We MITSUBISHI JUKOGYO KABUSHIKI KAISHA

of 5-1, Marunouchi 2-chome, Chiyoda-ku, Tokyo, JAPAN

hereby apply for the grant of a Patent for an invention entitled:

"CONTROL DEVICE FOR A VERTICAL SHAFT TYPE ENGINE"

which is described in the accompanying complete specification. This Application is a Convention Application and is based on the Application(s) numbered: 62-2878 for a Patent or similar protection made in Japan on 14th January, 1987.

Our address for service is:

GRIFFITH HASSEL & FRAZER
71 YORK STREET
SYDNEY N.S.W. 2000
AUSTRALIA

DATED this 12th day of January, 1988.

PATENTS ACT 1952 (AS AMENDED)

DECLARATION IN SUPPORT OF AN APPLICATION FOR A PATENT

(Name of applicant) In support of an Application made by:
Mitsubishi Jukogyo Kabushiki Kaisha

>Title for a patent for an invention entitled:
CONTROL DEVICE FOR A VERTICAL SHAFT TYPE ENGINE

(Full name of I, signatory) Nobuaki Akatsu

(Address of signatory) Mitsubishi Jukogyo Kabushiki Kaisha,
5-1, Marunouchi 2-chome, Chiyoda-ku, Tokyo, Japan

I, Nobuaki Akatsu, do solemnly and sincerely declare as follows:

1. I am authorised by the above mentioned applicant for the patent to make this Declaration on its behalf.

2. The name and address of each actual inventor of the invention is as follows:
Kazuyuki Kobayashi, c/o Nagoya Machinery Works of Mitsubishi Jukogyo Kabushiki Kaisha,
1, Aza Takamichi, Iwatsuka-cho,
Nakamura-ku, Nagoya-shi, Aichi-ken, Japan

and the fact(s) upon which the applicant is entitled to make this application are as follows:
The applicant is entitled to apply for a patent by virtue of an assignment from the inventor to the applicant.

3. The basic application(s) as defined by Section 141 of the Act was(were) made as follows:
Country Japan on January 14, 1987 in the name(s) Mitsubishi Jukogyo Kabushiki Kaisha
and in on in the name(s) and in on in the name(s)

4. The basic application(s) referred to in the preceding paragraph of this Declaration was(were) the first application(s) made in a Convention country in respect of the invention the subject of this application.

Declared at Tokyo, Japan this 4th day of January 1988
Mitsubishi Jukogyo Kabushiki Kaisha

Signed: Nobuaki Akatsu
Position: Managing Director

GRIFFITH HASSEL & FRAZER, P.O. BOX 2133, C.P.O., SYDNEY, N.S.W. 2001 AUSTRALIA
1. A control device for a vertical shaft type engine which controls a vertical shaft type engine mounted on a working machine from stoppage to choking; characterized in that a control means is constructed of a first control lever and a second control lever which are relatively rotatable and are arranged to rotate jointly within a predetermined range, said first control lever is connected to a governor spring and is rotatable between an engine stop switch terminal and a highest speed rotation regulating screw, said second control lever is provided with a connecting section which is arranged to be connected with a Bowden wire which is in turn connected to a manipulation lever on a working machine, a pair of engaging sections which are arranged to engage with said first control lever phase-shifted by 180° and a pair of contact sections which are arranged to engage
with a choke lever phase-shifted by 180° so that the
direction of movement of the connecting point between said
second control lever and said Bowden wire can be reversed by
remounting said second control lever as phase-shifted by
180°, and clamp sections for said Bowden wire are provided.
TO BE COMPLETED BY APPLICANT

Complete Specification for the invention entitled:

"CONTROL DEVICE FOR A VERTICAL SHAFT TYPE ENGINE"

The following statement is a full description of this invention, including the best method of performing it known to us:

7796A/bm
CONTROL DEVICE FOR A VERTICAL SHAFT TYPE ENGINE

BACKGROUND OF THE INVENTION:

Field of the Invention:

The present invention relates to a control device for a vertical shaft type engine.

Description of the Prior Art:

Among lawn mowers on which a vertical shaft type engine is mostly mounted, in many of them control of the engine is effected by means of single manipulation lever, and so, an engine control device provided with all the functions of stoppage, rotational speed regulation and choking, is necessitated.

In the prior art, as shown in Fig. 7, the control device has a structure in which a control lever 3 is rotatably mounted on a control panel 9 on which a stop switch terminal 10 is equipped, and one end of the control lever 3 can be brought into contact with a choke control plate 4.

A Bowden wire 1 has its outer cable fixedly secured to the control panel 9 by means of a wire clamp 8. An inner cable 2 of the Bowden wire 1 is moved in the forward and backward directions by manipulating a manipulation lever 21 on a working machine H as shown in Figs. 8 and 9, and one end of the inner cable 2 is connected to the control lever 3 (Fig. 7). When the control lever 3
has come closest to the wire clamp 8(A), it comes into contact with the stop switch terminal 10 to stop an engine E as shown in Fig. 7, while at the farthest position from the wire clamp 8(A), a rotational speed regulating screw 6 provided on the control lever 3 comes into contact with the choke control plate 4 and rotates the choke control plate 4, and the construction is such that a choke valve in a carburettor not shown is closed by a choke rod 5 connected to the choke control plate 4.

A rotational speed of the engine E is controlled by expanding and contracting a governor spring 7 engaged with the control lever 3 in accordance with rotation of the control lever 3, thus moving a governor lever (not shown) engaged with the other end of the governor spring 7 and regulating an opening angle of a carburettor throttle valve (not shown) connected to the governor lever. When the control lever 3 is close to the stop switch terminal 10 of the engine E, the engine E rotates at a low speed, but just before the control lever 3 comes into contact with the choke control lever 4, the engine starts to rotate at a high speed.

With regard to the manipulation lever 21 on the working machine H for controlling the engine E, there is a lever 21 of the type that engine E is accelerated to a high speed when the inner cable 2 of the Bowden wire 1 is
moved in the direction of projecting as shown in Fig. 9, and there is a lever 21 of another type that the engine E is accelerated to a high speed when the inner cable 2 of the Bowden wire 1 is moved in the direction of retracting. Consequently, in the case of a control device having such structure that when a manipulation lever 21 on a working machine H is manipulated in the direction of projecting an inner cable 2 of a Bowden wire 1, the engine E is accelerated to a high speed as shown in Fig. 9, a wire clamp position with respect to the control panel 9 is selected at 8(A) in Fig. 7, while in the case of a control device having such structure that when the manipulation lever 21 on the working machine H is manipulated in the direction of retracting the inner cable 2 of the Bowden wire 1, the engine E is accelerated to a high speed, the wire clamp position with respect to the control panel 9 is selected at 8(B) in Fig. 7.

In Fig. 8 are shown two examples of an attitude of mounting of an engine in the prior art, in the case where the engine E is choked when the manipulation lever 21 of the working machine H is manipulated in the direction of projecting the inner cable 2 of the Bowden wire 1. Since the stop switch terminal 10 is located in the direction of mounting of an ignition plug 22 on the engine E, in order to minimize the routing length of the inner cable
2 of the Bowden wire 1 on the working machine H, possible attitudes of mounting of an engine are only the two varieties shown in Figs. 8(a) and 8(b), respectively.

In the engine control device in the prior art in which an engine is manipulated from "stoppage" to "choking" by means of a single Bowden wire, there was a disadvantage that in order to simplify routing of the Bowden wire 1 a mounting attitude of an engine is restricted depending upon a direction of manipulation of a manipulation lever 21 on a working machine H, that is, depending upon whether the engine is accelerated to a high speed when the inner cable 2 of the Bowden wire 1 projects or it is accelerated to a high speed when the inner cable 2 is retracted, as described above.

In the case where the working machine H has such structure that it is accelerated to a high speed when the inner cable 2 projects, the mounting positions of the engine as shown in Figs. 8(a) and 8(b) are determinative and it was difficult to select the position of the ignition plug 22 as directed in the travelling direction of the working machine for the purpose of facilitating maintenance service.

SUMMARY OF THE INVENTION:

It is therefore one object of the present invention to provide an improved control device for a
vertical shaft type engine that is free from the
above-described disadvantage in the prior art.

A preferred object of the present invention is to
provide a control device for a vertical shaft type engine,
which makes it possible to arbitrarily select a mounting
attitude of the engine on a working machine regardless of a
structure of a manipulation lever on the working machine,
and which is advantageous for design and maintenance service.

According to the present invention there is provided a
control device for a vertical shaft type engine which
controls a vertical shaft type engine mounted on a working
machine from stoppage to choking; characterized in that a
control means is constructed of a first control lever and a
second control lever which are relatively rotatable and are
arranged to rotate jointly within a predetermined range,
said first control lever is connected to a governor spring
and is rotatable between an engine stop switch terminal and
a highest speed rotation regulating screw, said second
control lever is provided with a connecting section which is
arranged to be connected with a Bowden wire which is in turn
connected to a manipulation lever on a working machine, a
pair of engaging sections which are arranged to engage with
said first control lever phase-shifted by 180° and a pair of
contact sections which are arranged to engage with a choke
lever phase-shifted by 180° so that the direction of
movement of the connecting point between said second control
lever and said Bowden wire can be reversed by remounting
said second control lever as phase-shifted by 180°, and
clamp sections for said Bowden wire are provided.

Advantages of the preferred embodiment of the present invention of the control device for a vertical shaft type engine, are a mounting attitude of an engine can be arbitrarily selected regardless of the structure of a manipulation lever on a working machine, and hence, maintenance and service for an engine when it is mounted on a working machine, become easy.

The above-mentioned and other objects, features and advantages of the present invention will become more apparent by reference to the following description of one preferred embodiment of the invention taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS:

In the accompanying drawings, Figs. 1 to 6 show one preferred embodiment of the present invention, while Figs. 7 to 9 show one example of a control device in the prior art, wherein:

Fig. 1 is a plan view of a vertical shaft type engine embodying the present invention;
Fig. 2 is a side view of the same engine as viewed in the direction of arrow II in Fig. 1;

Fig. 3 is a disintegrated perspective view of a control device in the same engine as viewed in the direction of arrow III in Fig. 1;

Fig. 4 is a partial cross-section view of the same control device as viewed in the direction of arrow IV in Fig. 2 (omitting a control panel cover 30);

Fig. 5 is a partial side view of the same control device as viewed in the direction of arrow V in Fig. 4;

Fig. 6 is a schematic view showing different states of mounting of the control device shown in Figs. 1 to 5;

Fig. 7(a) is a front view of a control device in the prior art;

Fig. 7(b) is a schematic view showing a state of mounting the control device in Fig. 7(a) on an engine;

Fig. 8 is a plan view showing different states of mounting the control device in Fig. 7(a) on a working machine; and

Fig. 9 is an enlarged perspective view showing a structure of a manipulation lever on a working machine.
DESCRIPTION OF THE PREFERRED EMBODIMENT:

Now description will be made on one preferred embodiment of the present invention with reference to Figs. 1 through 6.

As shown in Figs. 1 and 2, an engine 100 is a vertical shaft type air-cooled general purpose engine, which is composed of an air cleaner 101, a fuel tank 102, a recoil starter 103, a muffler 104, a carburettor 105, a cylinder 106, an ignition plug 107, an output shaft 108, a control device 109 and the like.

With regard to the control device 109 which forms an essential part of the present invention, it will be described in detail with reference to Figs. 3 to 5.

A control panel 112 serving as a medium for mounting the control device 109 to an engine E, is fixedly secured to the engine E by means of bolts 111 and 114. Onto this control panel 112 is mounted a stop switch terminal 119 via an insulator 118, a choke lever 116 is rotatably mounted onto the panel 112 by means of a screw 149, a spacer 110, a washer 150 and a nut 151, furthermore a choke rod 152 adapted to be connected with the carburettor 105 is mounted on the choke lever 116, and a return spring 117 is stretched between the control panel 112 and the choke lever 116 in order that the choke lever 116 keep a choke valve not shown in the carburettor opened except
for the time when it is necessitated to close the choke valve.

In addition, a first control lever 122 for controlling a rotational speed of the engine E issandwiched between spacers 115 and 123 both made of resin for reducing friction upon rotation, it is associated with a second control lever 126 under the condition that a return spring 124 interposed therebetween for joint movement is applied with initial loading (both levers move due to a torsional pre-stress provided by the return spring. This pre-stress is larger than that of a governing spring), and they are fixedly assembled so as to be freely rotatable by means of screw washers 127, 141 and 140 and a nut 142.

On the first control lever 122 is mounted a governor spring 153 for regulating an opening angle of a throttle valve in the carburettor in order to maintain a rotational speed of the engine constant independently of a loading condition, and a contact end portion 122a of the first control lever 122 is adapted to come into contact with the stop switch terminal 119 when the first control lever 122 is rotated in the anticlockwise direction as viewed in Fig. 3. On the other hand, when the first control lever 122 is rotated in the clockwise direction as viewed in Fig. 3, another contact end portion 122b of the first control lever 122 is adapted to come into contact with a regulating screw 121 which restricts the highest rotational speed of the engine, and thereby the
rotational speed of the engine is controlled.

The second control lever 126 to which one end of the inner cable 2 of the Bowden wire 1 in the control device according to the present invention is connected at a hole 126e, is formed in such manner that it can be mounted in two alternative set conditions which are phase-shifted by 180° from each other. Under a first set condition, a hook section 122c of the first control lever 122 is engaged with an engaging section 126a or 126b (in the illustrated case, assumed to be "126a") of the second control lever 126, hence when the second control lever 126 rotates in the clockwise direction as viewed in Fig. 3, the first control lever 122 is jointly rotated due to the initial loading of the return spring 124, and after the first control lever 122 has been brought into contact with the highest speed regulating screw 121 and has been restricted in rotation, the engaging section 126a of the second control lever 126 is separated from the engaging section 122c of the first control lever 122, only the second control lever 126 rotates, then a contact section 126c with the choke lever 116 of the second control lever 126 comes into contact with a folded section 116a of the choke lever 116, and thereby the choke lever 116 is rotated in the clockwise direction as viewed in Fig. 3.

It is to be noted that the rotation of the second control
lever 126 is restricted by a notch 130a or 130b in a control panel cover 130.

Whereas, under a second set condition where the second control lever 126 is set as phase-shifted by 180° with respect to the first control lever 122, the second control lever 126 is engaged with the first control lever 122 at the engaging section 126b and engaged with the folded section 116a of the choke lever 116 at the engaging section 126d, and therefore, it becomes possible to change the position where the Bowden wire 1 in the control device according to the present invention is mounted to a mounting hole 126e in the second control lever 126 projecting from the control panel cover 130, by appropriately selecting the orientation of the second control lever 126 assembled with the first control lever 122.

Therefore, as shown in Fig. 3, in the control panel cover 130 are formed threaded holes 130e, 130f, 130g and 130h for clamping the outer cable of the Bowden wire at two locations on the left and right sides, respectively, that is, at four locations in total corresponding to the notches 130a and 130b so that the outer cable of the Bowden wire can be clamped at any one location among these four locations by means of a wire clamp 131 and a screw 132. In Fig. 6(a), reference characters E, F, G and H designate the clamp positions at the above-mentioned four
locations. Figs. 6(a) and 6(b) illustrate the cases where the engine is mounted with the position of the ignition plug 22 directed in the travelling direction of the working machine, Fig. 6(a) showing a control device having such structure that the engine is accelerated to a high speed when the manipulation lever on the working machine is moved in the direction of projecting the inner cable 2 of the Bowden wire 1, while Fig. 6(b) showing a control device having such structure that the engine is accelerated to a high speed when the manipulation lever on the working machine is moved in the direction of retracting the inner cable 2 of the Bowden wire 1. Figs. 6(c) and 6(d) illustrate the case where the engine is mounted with the position of the ignition plug 22 directed in the leftward direction with respect to the travelling direction of the working machine, Fig. 6(c) showing a control device having such structure that the engine is accelerated to a high speed when the manipulation lever on the working machine is moved in the direction of projecting the inner cable 2 of the Bowden wire 1, while Fig. 6(d) showing a control device having such structure that the engine is accelerated to a high speed when the manipulation lever on the working machine is moved in the direction of retracting the inner cable 2 of the Bowden wire 1. The set condition of the second control lever 126 and the clamped position of the
Bowden wire 1 in each case are as shown in the corresponding figure, and under the illustrated condition the inner cable 2 of the Bowden wire 1 is connected to the hole 126e in the second control lever 126.

Under the set condition where the second control lever 126 projects from the notch 130b in the control panel cover 130 with the ignition plug 22 directed in the travelling direction, when the second control lever 126 rotates in the clockwise direction, the engine is controlled sequentially in the mode of "stoppage" + "low speed" + "high speed" + "choking" (Fig. 6(b)).

Also, under the set condition where the second control lever 126 projects from the notch 130a in the control panel cover 130 with the ignition plug directed in the travelling direction, when the second control lever 126 rotates in the clockwise direction, the engine is controlled sequentially in the mode of "stoppage" + "low speed" + "high speed" + "choking" (Fig. 6(a)).

Under both the above-mentioned two exemplified conditions, as a result of rotation of the second control lever 126 in the clockwise direction the engine takes similar operating conditions sequentially in the mode of "stoppage" + "low speed" + "high speed" + "choking", but the directions of movement of the connecting point 126e between the second control lever 126 and the inner cable...
are opposite to each other for the respective conditions.

The same is also true when the set conditions illustrated in Figs. 6(c) and 6(d) where the engine is mounted with the ignition plug 22 directed in the leftward direction, are compared with each other.

Therefore, according to the present invention, since the attitude of mounting of the engine is not subjected to any restriction independently of the structure of a manipulation lever in a working machine such as a lawn mower, facility in maintenance for an ignition plug or a control device is not deteriorated and also routing of a Bowden wire can be simplified.

As described in detail above, in the control device according to the present invention it is possible to reverse the direction of movement of a control wire for an engine by merely modifying a method of assembling same component parts, an attitude of mounting of an engine can be arbitrarily chosen regardless of a structure of a manipulation lever on a working machine, and therefore, facility in maintenance for a control device, an ignition plug and the like can be improved.

Since many changes and modifications can be made to the above-described constructions without departing from the spirit of the present invention, all matter contained in the above description and illustrated in the
accompanying drawings shall be interpreted to be illustrative and not as a limitation to the scope of the invention.
THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:

1. A control device for a vertical shaft type engine which controls a vertical shaft type engine mounted on a working machine from stoppage to choking; characterized in that a control means is constructed of a first control lever and a second control lever which are relatively rotatable and are arranged to rotate jointly within a predetermined range, said first control lever is connected to a governor spring and is rotatable between an engine stop switch terminal and a highest speed rotation regulating screw, said second control lever is provided with a connecting section which is arranged to be connected with a Bowden wire which is in turn connected to a manipulation lever on a working machine, a pair of engaging sections which are arranged to engage with said first control lever phase-shifted by 180° and a pair of contact sections which are arranged to engage with a choke lever phase-shifted by 180° so that the direction of movement of the connecting point between said second control lever and said Bowden wire can be reversed by remounting said second control lever as phase-shifted by 180°, and clamp sections for said Bowden wire are provided.

2. A control device for a vertical shaft type engine as claimed in Claim 1, characterized in that said first and second control levers are disposed rotatably about a same axis on a control panel fixedly secured to the engine with said first control lever sandwiched between spacers made of resin and combined with said second control lever under the condition that a pre-stress is applied to a return spring
provided between the first and second control levers for joint movement.

3. A control device for a vertical shaft type engine as claimed in Claim 2, characterized in that a control panel cover is fixedly provided on said control panel, and said clamp sections for the Bowden wire are disposed on said control panel cover.

4. A control device for a vertical shaft type engine as claimed in Claim 3, characterized in that said control panel cover is provided with a notch or notches for restricting a rotatable range of said second control lever.

5. A control device for a vertical shaft type engine as claimed in Claim 4, characterized in that said notches are provided so that the second lever is rotated by 180° with respect to the first lever.

6. A control device substantially as hereinbefore described with reference to Figures 1 to 6 and Figure 9 of the accompanying drawings.
