Commonwealth of Australia.

APPLICATION TO BE IN PERSONAL NAMES UNLESS BY BODIES INCORPORATED BY LAW.
In support of the Convention application made by UNIROYAL CHEMICAL COMPANY, INC., a corporation organized under the laws of the state of New Jersey, one of the United States of America, located at World Headquarters, Middlebury, Connecticut 06749 (USA) for a patent/patent-of-addition for an invention entitled...

PROCESS FOR THE PRODUCTION OF 2-QUINOXALINES

I/We... I. J. Krakower

of (See above)

do solemnly and sincerely declare as follows:—

1. I am/We are the applicant(s) for the patent/patent-of-addition (or, in the case of an application by a body corporate) (oder im Falle einer Anmeldung einer juristischen Person)

1. I am/We are authorized by the abovementioned applicant(s) for the patent/patent-of-addition to make this declaration on its/their behalf.

2. The basic application(s) as defined by section 141 of the Act was/were made in the following country or countries on the following date(s) by the following applicant(s) namely:

   in the United States on June 19, 1987
   by Russell Edward Malz, Jr.
   on June 19, 1987
   by...

3. I am/We are the actual inventor(s) of the invention referred to in the basic application (or, where a person other than the inventor is the applicant) (oder wenn der Anmelder eine andere Person als der Erfinder ist)

   Russell Edward Malz, Jr., of
   261 Wedgewood Drive, Naugatuck, Connecticut 06770 USA
   of

is/are the actual inventor(s) of the invention and the facts upon which the applicant(s) is/are entitled to make the application are as follows:—

The Applicant Corporation is the Assignee of the actual inventor.

4. The basic application(s) referred to in paragraph 2 of this Declaration was/were the first application(s) made in a Convention country in respect of the invention the subject of the application.

Middlebury, Connecticut

Declared at:

this day of April 1988

UNIROYAL CHEMICAL COMPANY, INC.

Middlebury, Connecticut

I. J. Krakower Vice-President

To: The Commissioner of Patents, Commonwealth of Australia.
1. A process for preparing a 2-quinoxalinol compound of the formula:

wherein R is hydrogen, halogen or trihalomethyl; which process comprises reducing a 2-quinoxalinol-4-oxide compound of the formula:
wherein R is as defined above, with hydrogen in the presence of a catalytically effective amount of at least one catalyst selected from the group consisting of platinum, rhodium, ruthenium and nickel at between about 20° and about 150°C and at between about 6 and 60 atmospheres.
TO BE COMPLETED BY APPLICANT
UNIROYAL CHEMICAL COMPANY, INC.

Name of Applicant:

Address of Applicant:
World Headquarters, Middlebury, Connecticut
06749, United States of America

Actual Inventor:
Russell Edward Malz, Jr.

Address for Service:
care of R.K. MADDERN & ASSOCIATES,
345 King William Street, Adelaide,
South Australia, 5000.

Complete Specification for the invention entitled:
"PROCESS FOR THE PRODUCTION OF 2-QUINOXALINES"

The following statement is a full description of this invention, including the best method of performing it known to us.
ABSTRACT

Certain 2-quinoxalinol-4-oxides are selectively reduced to form 2-quinoxalinols employing hydrogen as a reducing agent by reacting such 2-quinoxalinol-4-oxides with a catalyst selected from the group consisting of platinum, rhodium, ruthenium and nickel at between about 20°C and about 150°C and at between about 6 and about 60 atmospheres.
PROCESS FOR THE PRODUCTION OF 2-QUINOXALINES

Field of the Invention

This invention is directed to an improved process for the production of certain 2-quinoxalinols by the selective reduction of 2-quinoxalinol-4-oxides employing a catalyst selected from the group consisting of platinum, rhodium, ruthenium and nickel in the presence of an aqueous hydroxide at between about 20°C and about 150°C and at between about 6 and about 60 atmospheres, employing hydrogen as the reducing agent.

Background of the Invention

2-quinoxalinol compounds, such as 5-chloro-2-hydroxyquinoxaline, are well known intermediates for the production of pharmaceutically and agriculturally effective chemicals. These compounds are generally prepared by the selective reduction of 2-quinoxalinol-4-oxides. Selective reduction is necessary so that excessive reduction, resulting in the formation of compounds such as 3,4-dihydro-2-quinoxalinol, can be avoided. This is particularly a problem with halogenated 2-quinoxalinol compounds wherein excessive hydrogenation will eliminate the halogen substituent.

Among the known processes for selectively reducing 2-quinoxalinol-4-oxides to 2-quinoxalinols is that described in United States Patent No. 4,636,562 to Davis.
This patent discloses a process for preparing 2-chloro-6-haloquinoxaline compounds from the corresponding 4-halo-2-nitroaniline, which process includes a step involving the reduction of 6-chloro-2-hydroxyquinoline-4-oxide to 6-chloro-2-hydroxyquinoline employing hydrogen as a reducing agent in the presence of an aqueous alkali metal hydroxide solvent and a transition element metal hydrogenation catalyst, preferably Raney nickel. However, this Davis process is also not desirably commercially employed because Davis indicates that hydrogen pressures of 1-4 atmospheres are effective with pressures of 1-2 atmospheres being preferred. It is well known to those of ordinary skill in the art that processes involving gaseous hydrogen at such low pressures are inherently dangerous because there is a risk of air leaking into the system. If hydrogen and oxygen contact the hydrogenation catalyst together, water is formed in an explosive manner.

Somewhat similarly, Sakata et al, "The Facile One Pot Synthesis of 6-Substituted 2(1H)-quinoxalinones", *Heterocycles*, Vol. 23, No. 1 (1985), disclose a process for the reduction of 6-chloro-2-quinoxalinol-4-oxide to 6-chloro-2-quinoxalinol employing hydrogen as a reducing agent and palladium as a catalyst. However, Sakata et al indicate such process has the drawback that an undesirable amount of overly reduced by-product is also formed.
United States Patent No. 4,620,003 to Ishikura discloses a process for the reduction of 2-quinoxalinol-4-oxide compounds to 2-quinoxinol compounds, which process involves reacting a 2-quinoxalinol-4-oxide with hydrazine in the presence of (i) a Raney catalyst (especially Raney nickel or sulfided Raney nickel) and (ii) an alkali metal hydroxide, an alkaline earth metal hydroxide, or ammonium hydroxide. While this process reduces the 2-quinoxalinol-4-oxides in desirable efficiencies, a major drawback in the commercial use of the Ishikura process is the relatively high cost of hydrazine relative to other potential reducing agents, in particular hydrogen.

Consequently, it would be desirable to possess a process for the selective reduction of 2-quinoxalinol-4-oxides to 2-quinoxalinols safely and efficiently employing hydrogen as a reducing agent.

Accordingly, it is an object of this invention to provide a method of selectively reducing 2-quinoxalinol-4-oxides to 2-quinoxalinols employing hydrogen as a reducing agent.

It is a further object of this invention to provide a high pressure method of selectively reducing 2-quinoxalinol-4-oxides to 2-quinoxalinols employing hydrogen as a reducing agent such that the danger of air leaking into the system is minimized.
The above objects and additional objects will become more fully apparent from the following description and accompanying examples.

Description of the Invention

The present invention is directed to a process for preparing a 2-quinoxalinol compound of the formula:

\[
\begin{align*}
R & \quad \text{OH} \\
\end{align*}
\]

wherein \( R \) is hydrogen, halogen or trihalomethyl; which process comprises reducing a 2-quinoxalinol-4-oxide compound of the formula:

\[
\begin{align*}
R & \quad \text{OH} \\
\end{align*}
\]

wherein \( R \) is as defined above, with hydrogen in the presence of a catalytically effective amount of at least one catalyst selected from the group consisting of platinum, rhodium, ruthenium and nickel at between about 20° and about 150°C and at between about 6 and about 60 atmospheres.
The 2-quinoxalinol-4-oxide compounds employed as starting materials in the process of this invention are of the formula:

\[
\begin{align*}
\text{R} & \quad \text{O} \\
\text{OH} & \quad \text{N}
\end{align*}
\]

wherein R is hydrogen, halogen or trihalomethyl. Preferably, R is hydrogen, chlorine, fluorine, trichloromethyl or trifluoromethyl. A particularly preferred starting material is 6-chloro-2-hydroxyquinoxaline-4-oxide, which is subsequently reduced to 6-chloro-2-hydroxyquinoxaline.

These starting materials may be in isolated form or may be present as a reaction product. Thus, for example, 6-chloro-2-hydroxyquinoxaline-4-oxide may be present as the product of the reaction of 4-chloro-2-nitroacetanilide with a hydroxide (such as sodium hydroxide or potassium hydroxide).

The process of this invention is catalyzed by a hydrogenation catalyst selected from the groups consisting of platinum, rhodium, ruthenium and nickel. Such catalysts are typically employed in amounts of about 0.01 to about 100 parts by weight per 100 parts by weight of 2-quinoxalinol-4-oxide.
When the starting material employed in the process of this invention is the reaction product of a nitroacetoanilide with a hydroxide, the reaction of this invention is conducted in a solution containing at least one compound selected from the group consisting of alkali metal hydroxides, alkaline earth metal hydroxides and ammonium hydroxide. Water is preferred as a reaction solvent but organic solvents (such as alcohols or hydrocarbons) or solvent mixtures of water with an organic solvent may also be employed.

The process of this invention is carried out at pressures between about 6 and about 60 atmospheres, with pressures of between about 8 and about 15 atmospheres being preferably employed. Reaction temperature may vary widely, with temperatures typically ranging between about 20° and about 150°C, and preferably ranging between about 30° and about 120°C.

The reaction temperatures and pressures which are most preferably employed will vary in accordance with a number of factors including the particular catalyst selected; the starting material employed; the catalyst concentration; and the like. As is apparent to one skilled in the art, reaction conditions which are too severe may reduce the selectivity of the reaction and produce products which may be too greatly reduced. Conversely, reaction conditions which are too mild will reduce the activity of the catalyst. Thus, for example, ruthenium under certain reaction conditions (i.e., a
pressure of 200 psig and a concentration of 0.4 pph by weight of starting material) require a higher activation temperature (of above 60°C). However, one of ordinary skill in the art may readily determine the optimum reaction conditions for a particular set of reactants by routine experimentation.

By employing methods well known to those skilled in the hydrogenation art, the process of this invention may be employed in a continuous or in a batch manner.

Because the process of this invention employs hydrogen as a reducing agent, it is greatly more economical than prior art processes employing relatively expensive chemicals (such as hydrazine) as reducing agents. Moreover, because the process of this invention is conducted at relatively high pressures, the danger of an explosion occurring due to the leaking in of air is greatly reduced.

Examples

The following Examples are intended to further illustrate the invention and are not intended to limit the scope of the invention in any manner whatsoever.

Examples 1-5 and Comparative Experiment A

To a 300 ml autoclave equipped with an agitator was added a stock solution containing 0.15 mole of 6-chloro-2-hydroxyquinoxaline-4-oxide (which had been produced by the reaction of 482.4 grams of 4-chloronitroacetoacetanilide with 813 grams of 89 potassium hydroxide...
in 3200 grams of water) in a 17.6 weight percent aqueous potassium hydroxide solution. The amount and type of catalyst indicated in Table I below was added and the autoclave sealed. In this regard, it is to be noted that, with the exception of Example 4 (which employed Raney Nickel), all catalysts were 5 weight percent on carbon. The autoclave was purged, first with nitrogen and subsequently with hydrogen. Hydrogen was added until the reaction pressure was 200 psig. The autoclave was heated to 60° with agitation for the indicated reaction time, and was then cooled and depressurized. (Note: Example 5 was conducted at 120°C and 200 psig; Comparative Experiment A was conducted at 30°C and at 450-700 psig). The reaction product was removed with water, filtered through celite (to remove catalyst), and dried. The reaction product was analyzed, and the yield (based upon the complete cyclization, reduction, neutralization, filtration and drying steps) calculated. The results of such analyses are presented in Table I.

* Based upon molar conversion of 4-chloronitroacetanilide into 6-chloro-2-hydroxyquinoline.

The above data indicate the admirable yields of selectively reduced product produced employing the process of this invention. These yields are unexpected in view of the lack of selectivity exhibited by a very closely related catalyst, palladium.
CLAIMS
THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:

1. A process for preparing a 2-quinoxalinol compound of the formula:

\[
\begin{align*}
\text{N} & \quad \text{R} \\
\text{N} & \quad \text{OH}
\end{align*}
\]

wherein R is hydrogen, halogen or trihalomethyl; which process comprises reducing a 2-quinoxalinol-4-oxide compound of the formula:

\[
\begin{align*}
\text{N} & \quad \text{R} \\
\text{N} & \quad \text{OH}
\end{align*}
\]

wherein R is as defined above, with hydrogen in the presence of a catalytically effective amount of at least one catalyst selected from the group consisting of platinum, rhodium, ruthenium and nickel at between about 20° and about 150°C and at between about 6 and 60 atmospheres.

2. A process in accordance with claim 1 wherein said 2-quinoxalinol-4-oxide is in a solution further comprising at least one compound selected from the group consisting of alkali metal hydroxides, alkaline earth metal hydroxides and ammonium hydroxide.
3. A process in accordance with claim 1 wherein R is selected from the group consisting of hydrogen, chlorine, fluorine, trichloromethyl and trifluoromethyl.

4. A process in accordance with claim 1 wherein the starting material is 6-chloro-2-hydroxyquinoline-4-oxide.

5. A process in accordance with claim 1 wherein the reduction takes place at between about 30°C and about 120°C.

6. A process in accordance with claim 1 wherein the reduction takes place at between about 8 and about 15 atmospheres.

7. A process for preparing 6-chloro-2-hydroxyquinoline from 6-chloro-2-hydroxyquinoline-4-oxide which process reacting 6-chloro-2-hydroxyquinoline-4-oxide with hydrogen in the presence of (a) a catalytically effective amount of at least one member selected from the group consisting of platinum, rhodium, ruthenium and nickel and (b) an aqueous solution of an alkali metal hydroxide at between about 20°C and about 150°C and at between about 6 and about 60 atmospheres.

8. A process in accordance with claim 7 wherein such reaction occurs at between about 30°C and about 120°C and at between about 8 and about 15 atmospheres.
9. A process according to claim 1 substantially as described in any one of Examples 1 to 5 herein.

Dated this 8th day of June, 1988.
