**Mechanism of Erythropoietin production**

Renal interstitial peritubular cells detect low blood oxygen levels. Erythropoietin (EPO) stimulates the proliferation and differentiation of erythroid progenitors into reticulocytes, and prevents apoptosis.

EPO stimulates the proliferation and differentiation of erythroid progenitors into reticulocytes, and prevents apoptosis.

Increased oxygen delivery to tissues.

Figure 1

**Abstract:** Provided herein are isolated populations of kidney cells harvested from differentiated cells of the kidney, wherein cells have been expanded *in vitro*. The kidney cells may include peritubular interstitial cells of the kidney, and preferably produce erythropoietin (EPO). The kidney cells may also be selected based upon EPO production. Methods of producing an isolated population of EPO producing cells are also provided, and methods of treating a kidney disease resulting in decreased EPO production in a patient in need thereof are provided, including administering the population to the patient, whereby the cells produce EPO *in vivo*. 
SELECTIVE CELL THERAPY FOR THE TREATMENT OF RENAL FAILURE

Anthony Atala and James J. Yoo

Related Applications

This application claims the benefit under 35 U.S.C. § 119(e) of United States Provisional Patent Application Serial Number 60/942,716, filed June 8, 2007, the disclosure of which is incorporated herein by reference in its entirety.

Field of the Invention

The present invention is in the field of selective cell therapy for the restoration of organ function.

Background of the Invention

Chronic renal failure is characterized by a gradual loss in kidney function, and may eventually progress to end stage renal failure, where the kidney no longer functions at a level to sustain the body. End stage renal failure is a devastating disease that involves multiple organs in affected individuals. The most common cause of end stage renal disease in the U.S. is diabetes.

One of the functions performed by the kidney is the production of erythropoietin (EPO). When the kidney is functioning properly, low tissue oxygenation in the renal interstitium stimulates the interstitial cells to produce EPO. The secreted EPO in turn stimulates red blood cell production in the bone marrow, which restores tissue oxygen tension to normal levels. Anemia caused by ineffective hematopoiesis is one of the inevitable outcomes of chronic renal failure due to the kidney’s decreased ability to produce EPO. EPO has also been reported to protect against oxidative stress and apoptosis.

The kidney is the primary producer of EPO in the body and is therefore a primary target of treatment for renal failure induced anemia. Although dialysis can prolong survival for many patients with end stage renal disease, only renal transplantation can currently restore normal function. However, renal transplantation is severely limited by a critical donor shortage.
Treatments used to alleviate anemia associated with renal failure over the years include repeated transfusions of red blood cells and administration of testosterone and other anabolic steroids. However, none of these modalities has been entirely satisfactory. Patients receiving repeated transfusions are subject to iron overload, and may develop antibodies to major histocompatibility antigens. Testosterone has a minimal effect on erythropoiesis in the bone marrow, and it is associated with undesirable, virilizing side effects.

Previous efforts to mitigate anemia associated with renal failure have included the administration of purified recombinant EPO (See, e.g., U.S. Patent Nos. 6,747,002 to Cheung et al., 6,784,154 to Westenfelder). However, the administration of recombinant EPO only elevates EPO levels in the blood temporarily, and may lead to iron deficiency. Gene therapy approaches have also been pursued, in which EPO is produced using transfected host cells (See, e.g., U.S. Patent Nos. 5,994,127 to Selden et al., 5,952,226 to Aebischer et al., 6,777,205 to Carcagno et al.; Rinsch et al. (2002) Kidney International 62:1395-1401). However, these approaches involve the transfection of non-kidney cells, and require techniques such as cell encapsulation to prevent antigen recognition and immune rejection upon transplantation. Also, transfection with exogenous DNA may be unstable, and the cells may lose their ability to express EPO over time.

Renal cell-based approaches to the replacement of kidney tissue is limited by the need to identify and expand renal cells in sufficient quantities. In addition, the culturing of renal cells for the purpose of kidney tissue engineering is particularly difficult, owing to the kidney's unique structural and cellular heterogeneity. The kidney is a complex organ with multiple functions, including waste excretion, body homeostasis, electrolyte balance, solute transport, as well as hormone production.

There remains a great need for alternative treatment options to alleviate anemia caused by the failure of renal cells to produce sufficient amounts of erythropoietin.
Summary of the Invention

According to one embodiment of the invention there is provided an isolated population of cells comprising differentiated peritubular interstitial cells harvested from mammalian kidney tissue and passaged in vitro, wherein at least 20% or more of the cells of said population produce erythropoietin (EPO) under normoxic conditions without manipulation by an exogenous chemical that stimulates the production of EPO.

According to another embodiment there is provided a method of producing an isolated population of EPO producing cells, said method comprising the steps of:

1. providing differentiated mammalian kidney cells; and
2. passaging said differentiated kidney cells, wherein at least 20% or more of said cells produce EPO under normoxic conditions without manipulation by an exogenous chemical that stimulates the production of EPO after said passaging;

thereby producing an isolated population of EPO producing cells.

In some embodiments, the passaging step includes growth of differentiated kidney cells in a medium comprising insulin transferrin selenium (ITS).

Methods of treating a kidney disease or other ailment, which disease or ailment results in decreased EPO production in a subject (e.g., a patient) in need thereof are also provided.

According to one embodiment there is provided a method of treating a kidney disease resulting in decreased EPO production in a patient in need thereof, said method comprising:

1. providing a composition comprising an isolated population of EPO producing cells in a pharmaceutically acceptable carrier, wherein at least 20% or more of said cells produce EPO under normoxic conditions without manipulation by an exogenous chemical that stimulates the production of EPO; and
2. administering said composition to said patient, whereby said EPO producing cells produce EPO in vivo.

In some embodiments, the providing step is performed by harvesting differentiated kidney cells of the kidney and passaging the cells in vitro. In some embodiments, the population of EPO producing cells includes, consists of or consists essentially of differentiated peritubular endothelial and/or interstitial cells harvested from differentiated cells of the kidney and passaged in vitro. In some embodiments, the population is provided in a suitable carrier (e.g., a collagen gel) for administration. In some embodiments, the administering step is carried out by implanting the population of cells into the kidney of the patient. In some
embodiments, the administering step is carried out by subcutaneously injecting or implanting said composition. In some embodiments, the EPO producing cells are human.

Further provided are isolated populations of cells including differentiated human kidney cells harvested from human kidney tissue and passaged in vitro.

According to one embodiment, there is provided an isolated population of cells comprising differentiated human kidney cells harvested from human kidney tissue and passaged in vitro, wherein at least 20% or more of the cells of said population produce EPO under normoxic conditions without manipulation by an exogenous chemical that stimulates the production of EPO.

In some embodiments, the kidney cells consist of or consist essentially of peritubular interstitial and/or endothelial cells of the kidney harvested from kidney tissue and passaged in vitro. In some embodiments, the differentiated human kidney cells produce EPO. In some embodiments, the human kidney cells have been passaged from 1-20 times. In some embodiments, the human kidney cells have been passaged at least 3 times. In some embodiments, the population has been selected for EPO production. Some embodiments are subject to the proviso that the cells are not transfected with an exogenous DNA encoding a polypeptide.

Compositions comprising the population of human kidney cells as described herein and a pharmaceutically acceptable carrier are also provided. In some embodiments, the carrier comprises collagen or hydrogel.

Another aspect of the present invention is the use of the methods as described herein for the preparation of a composition or medicament for use in treatment or for carrying out a method of treatment as described herein (e.g., for treating a kidney disease or other ailment resulting in decreased EPO production), or for making an article of manufacture as described herein.
According to one embodiment, the invention provides for use of an isolated population of cells in the manufacture of a medicament for the treatment of kidney disease in a subject, wherein said cells comprise differentiated peritubular interstitial cells harvested from mammalian kidney tissue and passaged in vitro, wherein at least 20% or more of the cells of said population produce EPO under normoxic conditions without manipulation by an exogenous chemical that stimulates the production of EPO.

**Brief Descriptions of the Drawings**

**Figure 1.** Mechanism of erythropoietin (EPO) production. Renal interstitial peritubular cells of the kidney detect low blood oxygen levels, and EPO is secreted into the blood. EPO stimulates the proliferation and differentiation of erythroid progenitors into reticulocytes, and prevents apoptosis, causing more reticulocytes to enter the circulating blood. The reticulocytes differentiate into erythrocytes, increasing the erythron size. Oxygen delivery to the tissues is thereby increased.

**Figure 2.** Intracellular erythropoietin immunoreactivity was confirmed in the primary culture of renal cells at passage 1 (P1), passage 2 (P2) and passage 3 (P3), compared to the negative control (X400).

**Figure 3.** Microscopy images of erythropoietin expressing cells in kidney tissue (left panel) and in cultured kidney cells (right panel).

**Figure 4.** Quantification of erythropoietin (EPO) producing cells. The number of cells expressing EPO decreased with the subsequent passages (* p<0.05).

**Figure 5.** Western blot analysis of detergent-solubilized cell extracts detected EPO protein (34 kDa) of early passage primary cultured renal cells (P0-P3).

**Figure 6.** EPO expression analysis using FACS. Top Row: Mouse cells, passages 0-3. Bottom Row: Rat cells, passages 0-3.
Figure 7A-7B. Mouse renal cell characterization. EPO expression is confirmed by immunofluorescence (Figure 7A) (KNRK cells were used as positive control). GLEPP1 and Tamm Horsfall kidney markers were also detected (Figure 7B).

Figure 8. Rat renal cell characterization. Cultured rat kidney cells have various cell morphologies shown by phase contrast microscope (left panels), and express GLEPP1 and Tamm Horsfall kidney markers (right panels).

Figure 9. EPO expression in HepG2 cells was shown by western blot and compared with EPO expression in kidney tissue.

Figure 10. EPO protein expression of cultured cells under hypoxic conditions. Lewis rat kidney cells and HepG2 cells were cultured under normal and hypoxic conditions, and EPO production was assessed by western blot of cells. 34kDa=EPO; 43kDa=β-Actin.

Figure 11. EPO protein expression in the culture medium under hypoxic conditions. EPO in the culture medium of Lewis rat kidney cells and HepG2 cells was assessed by western blot. 34kDa=EPO; 43kDa=β-Actin.

Figure 12. Total protein lysates were prepared from rat renal primary cells at passages 1 and 2. Plates from normoxic samples (NC), samples in 3%O2 and 7%O2 were processed and run on 10% SDS-PAGE. KNRK cell line was used as positive control.

Figure 13. Measuring EPO in media concentrates by western blot. Primary cultured cells from Lewis rats were raised close to confluency at each passage on 10cm plates. The cells were starved with KSFM for 24hrs and then placed in a hypoxic chamber (1% O2) for 24, 48 or 72 hrs. Following hypoxia incubation, the media was collected and concentrated with a 10K mwco amicon ultra centrifugal device (Millipore). 40ug of total protein was then loaded on a 10% polyacrylamide gel. KNRK cells were used as positive control.

Figure 14. Histological analysis of the retrieved implants showed that the kidney cells survived and formed tissue in vivo. Presence of EPO producing cells were confirmed immunohistochemically using EPO specific antibodies (X400). Left panel: Initial cell density of 1x10^6 cells/injection. Right panel: Initial cell density of 1x10^6 cells/injection. Top row of each panel: 2 weeks. Bottom row of each panel: 4 weeks.
Figure 15. Effect of culture media and hypoxia on renal primary cells measured by real time PCR. Renal primary cells (p0) were grown to 80% confluency in 10cm plates. Three plates of cells were grown with either serum free KSFM or DMEM and placed in a hypoxic chamber at 3% O2. After 24 hrs, samples were processed for total RNA and cDNA synthesis. Real time PCR was done in triplicate, and samples were quantified relative to normoxic sample.

Figure 16. Effect of hypoxia on renal primary cells measured by real time PCR. Renal primary cells (passages 0 and 2) were grown to 80% confluency in 10cm plates. Cells were then grown in serum free KSFM and placed in a hypoxic chamber at 1% O2. After 24, 48 or 72 hrs, samples were processed for total RNA and cDNA synthesis. Real time PCR was done in triplicate, and samples were quantified relative to normoxic sample.

Figure 17. Effect of hypoxia on renal primary cells measured by real time PCR. Renal primary cells (passage 0) were grown to 80% confluency in 10cm plates. Cells were then placed in a hypoxic chamber at 1%O2 for up to 24hrs. Samples were then processed for total RNA and cDNA synthesis. Real time PCR was done in triplicate, and samples were quantified relative to normoxic sample.

Figure 18. Primary human kidney cells were expanded. Shown are cells of passages 2, 4, 7 and 9.

Figure 19. Human primary renal cells were maintained through 20 doublings.

Figure 20. Human kidney cell characterization. GLEPP1 and EPO positive cells are present in the population.

Figure 21. Human kidney cell delivery in vivo with a 20 mg/ml collagen carrier. At retrieval, 3 weeks after injection, the injection volume had been maintained, and neovascularization was present.

Figure 22. Injection of collagen with cultured human kidney cells resulted in EPO expressing tissue formation in vivo.

Detailed Description of the Preferred Embodiments

Cell based therapy for renal failure can be approached in two directions: total and selective. Described herein is the selective cell therapy approach for achieving restoration of specific functional organ components.
The disclosures of all United States patent references cited herein are hereby incorporated by reference to the extent they are consistent with the disclosure set forth herein. As used herein in the description of the invention and the appended claims, the singular forms "a," "an" and "the" are intended to include the plural forms as well, unless the context clearly indicates otherwise. Furthermore, the terms "about" and "approximately" as used herein when referring to a measurable value such as an amount of a compound, dose, time, temperature, and the like, is meant to encompass variations of 20%, 10%, 5%, 1%, 0.5%, or even 0.1% of the specified amount. Also, as used herein, "and/or" or "/" refers to and encompasses any and all possible combinations of one or more of the associated listed items, as well as the lack of combinations when interpreted in the alternative ("or").

"Kidney tissue" is tissue isolated or harvested from the kidney, which tissue contains kidney cells. In some embodiments, kidney cells are positive for one or more known kidney markers, e.g., GLEPP1, Tamm Horsfall, etc. "Cell" or "cells" may be of any suitable species, and in some embodiments are of the same species as the subject into which tissues produced by the processes herein are implanted. Mammalian cells (including mouse, rat, dog, cat, monkey and human cells) are in some embodiments particularly preferred. "Isolated" as used herein signifies that the cells are placed into conditions other than their natural environment. Tissue or cells are "harvested" when initially isolated from a subject, e.g., a primary explant.

"Subjects" are generally human subjects and include, but are not limited to, "patients." The subjects may be male or female and may be of any race or ethnicity, including, but not limited to, Caucasian, African-American, African, Asian, Hispanic, Indian, etc. The subjects may be of any age, including newborn, neonate, infant, child, adolescent, adult, and geriatric.

Subjects may also include animal subjects, particularly mammalian subjects such as canines, felines, bovines, caprines, equines, ovines, porcines, rodents (e.g., rats and mice), lagomorphs, non-human primates, etc., for, e.g., veterinary medicine and/or pharmaceutical drug development purposes.

Cells may be syngeneic (i.e., genetically identical or closely related, so as to minimize tissue transplant rejection), allogeneic (i.e., from a non-genetically identical member of the same species) or xenogeneic (i.e., from a member of a different species).
Syngeneic cells include those that are autogeneic (i.e., from the patient to be treated) and isogeneic (i.e., a genetically identical but different subject, e.g., from an identical twin). Cells may be obtained from, e.g., a donor (either living or cadaveric) or derived from an established cell strain or cell line. Cells may be harvested from a donor, e.g., using standard biopsy techniques known in the art.

The "primary culture" is the first culture to become established after seeding disaggregated cells or primary explants into a culture vessel. "Expanding" as used herein refers to an increase in number of viable cells. Expanding may be accomplished by, e.g., "growing" the cells through one or more cell cycles, wherein at least a portion of the cells divide to produce additional cells.

"Passaged in vitro" or "passaged" refers to the transfer or subculture of a cell culture to a second culture vessel, usually implying mechanical or enzymatic disaggregation, reseeding, and often division into two or more daughter cultures, depending upon the rate of proliferation. If the population is selected for a particular genotype or phenotype, the culture becomes a "cell strain" upon subculture, i.e., the culture is homogeneous and possesses desirable characteristics (e.g., the ability to express EPO).

"Express" or "expression" of EPO means that a gene encoding EPO is transcribed, and preferably, translated. Typically, according to the present invention, expression of an EPO coding region will result in production of the encoded polypeptide, such that the cell is an "EPO producing cell." In some embodiments, cells produce EPO without further manipulation such as the introduction of an exogenous gene. In some embodiments, the invention is subject to the proviso that the EPO producing cells are not manipulated by the introduction of an exogenous gene and/or by an exogenous chemical that stimulates the production of EPO.

In some embodiments, harvested cells are not passaged. In other embodiments, cells are passaged once, twice, or three times. In still other embodiments, cells are passaged more than 3 times. In some embodiments, cells are passaged 0-1, 0-2 or 0-3 times. In some embodiments, cells are passaged 1-2, 1-3, or 1-4 or more times. In some embodiments, cells are passaged 2-3 or 2-4 or more times. In further embodiments, cells are passaged 5, 8, 10, 12 or 15 or more times. In some embodiments, cells are passaged 0, 1, 2, 3 or 4 to 8, 10, 15 or 20 or more times. The number of passages used
may be selected by, e.g., the relative EPO production measured in the cell population after each passage.

Growing and expansion of kidney cells is particularly challenging because these cells are prone to the cessation of growth and early differentiation. This challenge is overcome in some embodiments of the present invention by using kidney cell specific media that contains additives that promote their growth. Accordingly, in some embodiments kidney cells are grown in media that includes additives such as growth factors and other supplements that promote their growth. Further, in some embodiments, EPO producing cells are grown in co-culture with other renal cell types.

In some embodiments, kidney cells are grown in Dulbecco’s Modified Eagle’s Medium (DMEM) supplemented with 10% fetal bovine serum (FBS) or fetal calf serum (FCS) and, optionally, penicillin-streptomycin (P/S). In other embodiments, kidney cells are grown in keratinocyte serum-free medium (KSFM). In further embodiments, kidney cells are grown in KSFM with one or more of the following additives: bovine pituitary extract (BPE) (e.g., 50g/mL), epidermal growth factor (EGF) (e.g., 5ng/mL), antibiotic-antimyotic solution (GIBCO) (e.g., 5 mL), fetal bovine serum (FBS) (Gemini Bio-Product) (e.g., 12.5 mL of 2.5%), and insulin transferrin selenium (ITS) (Roche) (e.g., 50mg for 5L medium). As understood by those of skill in the art, in some embodiments of the above media, penicillin-streptomycin (P/S) and antibiotic-antimyotic solution are interchangeable.

Passaging of kidney cells according to some embodiments may be accomplished using standard procedures known in the art. For example, the cells may be detached using trypsin/EDTA and transferred to other plates. This is a standard procedure for many cell types. Briefly, in some embodiments this may be accomplished with the following steps: 1) Remove medium. 2) Add 10 ml PBS/EDTA (0.5 M) for 4 minutes. Confirm the separation of cell junctions under a phase contrast microscope. 3) Remove PBS/EDTA and add 7 ml Trypsin/EDTA. 4) Add 5 ml medium when 80-90% of the cells lift under microscope. 5) Aspirate the cell suspension into a 15 ml test tube. 6) Centrifuge the cells at 1000 rpm for 4 minutes. 7) Remove the supernatant. 8) Resuspend cells in 5 ml of medium. 9) Pipet out 100 µl of the cell suspension and perform trypan blue stain for viability assay. 10) Count the number of cells on
11) Aliquot the desired number of cells on the plate and make the volume of medium to a total of 10ml. 12) Place the cells in the incubator.

"Selection" can be based upon any unique properties that distinguish one cell type from another, e.g., density, size, unique markers, unique metabolic pathways, nutritional requirements, protein expression, protein excretion, etc. For example, cells may be selected based on density and size with the use of centrifugal gradients. Unique markers may be selected with fluorescent activated cell sorting (FASC), immunomagnetic bead sorting, magnetic activated cell sorting (MASC), panning, etc. Unique metabolic pathways and nutritional requirements may be exploited by varying the makeup and/or quantity of nutritional ingredients of the medium on which cells are grown, particularly in a serum-free environment. Protein expression and/or excretion may be detected with various assays, e.g., ELISA.

"EPO producing cell" refers to differentiated cells, of which at least a portion produce EPO (e.g., at least 20, 30, 40, or 50% or more, or more preferably 60, 70, 80, or 90% or more of the cells produce EPO). In some embodiments, cells produce EPO without further manipulation such as the introduction of an exogenous gene. In some embodiments, the invention is subject to the proviso that the EPO producing cells are not manipulated by the introduction of an exogenous gene and/or by an exogenous chemical that stimulates the production of EPO. The cells may be harvested from, e.g., the peritubular interstitial cells of the kidney. In some embodiments, the cells are selected for their ability to produce EPO. In other embodiments, the cells are expanded in number by cell culture techniques, e.g., passaging. Cells with the specific function of EPO production can be used from the kidney and from other sources. For example, EPO is also normally produced in the liver.

In the kidney, EPO is generally known to be produced by the interstitial peritubular cells (Figure 1). In some embodiments, an isolated population of differentiated kidney cells comprises, consists of or consists essentially of interstitial peritubular cells of the kidney, consisting of or consisting essentially of 80, 90, 95, or 99 percent or more, or not more than 20, 10, 5 or 1 percent or less, by number of other cell types. In other embodiments, the isolated population of differentiated kidney cells includes other cell types, e.g., endothelial peritubular cells.
In some embodiments, the isolated population of differentiated kidney cells comprises, consists of or consists essentially of kidney cells that are selected for EPO production, consisting of or consisting essentially of 80, 90, 95, or 99 percent or more, or not more than 20, 10, 5 or 1 percent or less, by number of cells not expressing EPO. Selection may be accomplished by selecting the cells that express EPO using specific markers. In some embodiments, cells may include various types of kidney cells, so long as the cells express EPO. In further embodiments, the entire renal cell colony may be used for expansion and treatment.

In some embodiments, the isolated population of differentiated kidney cells have a “longevity” such that they are capable of growing through at least 5, 10, 15, 20, 25 or 30 or more population doublings when grown in vitro. In some embodiments, the cells are capable of proliferating through 40, 50 or 60 population doublings or more when grown in vitro.

"Differentiated" refers to cells or a population containing cells that have specialized functions, e.g., EPO production and/or expression of known markers of differentiated cells (e.g., GLEPP1 and/or Tamm Horsfall kidney cell markers). In this sense they are not progenitor or stem cells. Some embodiments of the present invention are subject to the proviso that harvested differentiated cells are not passaged under conditions to create a population of less specialized cells.

Alternatively, in other embodiments, cells are cultured to produce cell lines, which may later be differentiated to produce more specialized cells. The establishment of "cell lines," as opposed to cell strains, are by and large undifferentiated, though they may be committed to a particular lineage. Propagation naturally favors the proliferative phenotype, and in some embodiments cells may require a reinduction of differentiation by, e.g., alteration of the culture conditions. There are a number of differentiation factors known in the art that may induce differentiation in cell lines (e.g., cytokines such as epimorphin and HGF, vitamins, etc.).

Methods of Treatment.

In some embodiments, EPO producing cells are administered to a subject in need thereof (e.g., by injection) to the kidney (e.g., into the cortex and/or medulla). In other embodiments, EPO producing cells are administered to other areas of the body,
e.g., the liver, peritoneum, etc. In some embodiments, the EPO producing cells are administered subcutaneously, subcapsular, etc. In further embodiments, EPO producing cells are administered by implantation of a substrate (e.g., a collagen gel scaffold) containing said EPO producing cells described herein. In still other embodiments, EPO producing cells are administered through vascular access (e.g., systemically or locally).

Diseases that may be treated with the methods disclosed herein include, but are not limited to, anemias. Anemias include, but are not limited to, those associated with renal failure or end-stage renal disease, anemias caused by chemotherapies or radiation, anemias of chronic disorders, e.g., chronic infections, autoimmune diseases, rheumatoid arthritis, AIDS, malignancies, anemia of prematurity, anemia of hypothyroidism, anemia of malnutrition (e.g., iron deficiency), and anemias associated with blood disorders.

"Treat" refers to any type of treatment that imparts a benefit to a patient, e.g., a patient afflicted with or at risk for developing a disease (e.g., kidney disease, anemia, etc.). Treating includes actions taken and actions refrained from being taken for the purpose of improving the condition of the patient (e.g., the relief of one or more symptoms), delay in the onset or progression of the disease, etc.

Other endocrine systems may benefit from the therapies disclosed herein, for example, vitamin D producing cell therapy or the angiotensin system. See, e.g., U.S. Patent Application Publication No. 2005/0002915 to Atala et al., which is incorporated herein by reference. Cells with a specific function can be used from the kidney and other sources, i.e., cells that would produce target functions. For example, EPO is also normally produced in the liver.

Preferably the cells are mixed with or seeded onto a pharmaceutically acceptable carrier prior to administration. "Pharmaceutically acceptable" means that the compound or composition is suitable for administration to a subject to achieve the treatments described herein, without unduly deleterious side effects in light of the severity of the disease and necessity of the treatment. Such formulations can be prepared using techniques well known in the art. See, e.g., U.S. Patent Application 2003/0180289; Remington: The Science and Practice of Pharmacy, Alfonso R. Gennaro, editor, 20th ed. Lippincott Williams & Wilkins: Philadelphia, PA, 2000. The carrier may be a solid or a liquid, or both (e.g., hydrogels), and can be formulated with
the cells as a unit-dose formulation. In some embodiments the cells are provided as a suspension in the carrier to reduce clumping of the cells. In other embodiments cells are seeded onto a biodegradable scaffold or matrix.

In some embodiments, cells are mixed with a suitable gel for administration. Suitable gels that may be used in the present invention include, but are not limited to, agars, collagen, fibrin, hydrogels, etc. Besides gels, other support compounds may also be utilized in the present invention. Extracellular matrix analogs, for example, may be combined with support gels to optimize or functionalize the gel. One or more growth factors may also be introduced into the cell suspensions.

Formulations of the invention include those for parenteral administration (e.g., subcutaneous, intramuscular, intradermal, intravenous, intraarterial, intraperitoneal injection) by injection or implantation. In one embodiment, administration is carried out intravascularly, either by simple injection, or by injection through a catheter positioned in a suitable blood vessel, such as a renal artery. In some embodiments, administration is carried out by "infusion," whereby compositions are introduced into the body through a vein (e.g., the portal vein). In another embodiment, administration is carried out as a graft to an organ or tissue to be augmented as discussed above, e.g., kidney and/or liver.

A "biodegradable scaffold or matrix" is any substance not having toxic or injurious effects on biological function and is capable of being broken down into elemental components by a host. Preferably, the scaffold or matrix is porous to allow for cell deposition both on and in the pores of the matrix. Such formulations can be prepared by supplying at least one cell population to a biodegradable scaffold to seed the cell population on and/or into the scaffold. The seeded scaffold may then be implanted in the body of a recipient subject.

In some embodiments, cells are administered by injection of the cells (e.g., in a suitable carrier) directly into the tissue of a subject. For example, cells may be injected into the kidney (e.g., the subcapsular space of the kidney). Because the functional effects of EPO production will be systemic, cells may also be administered by injection into other tissues (e.g., the liver, subcutaneously, etc.).

Cells may also be delivered systemically. In further embodiments, cells are delivered to tissue outside of the kidney (e.g., the liver), as the outcome of the
functional effects of EPO production will be systemic. See, e.g., the "Edmonton protocol," an established delivery method, where cells are infused into a patient's portal vein (Shapiro et al. (2000) N Engl J Med 343:230-238).

According to some embodiments, the cells administered to the subject may be syngeneic (i.e., genetically identical or closely related, so as to minimize tissue transplant rejection), allogeneic (i.e., from a non-genetically identical member of the same species) or xenogeneic (i.e., from a member of a different species), as above, with respect to the subject being treated, depending upon other steps such as the presence or absence of encapsulation or the administration of immune suppression therapy of the cells. Syngeneic cells include those that are autogeneic (i.e., from the subject to be treated) and isogeneic (i.e., a genetically identical but different subject, e.g., from an identical twin). Cells may be obtained from, e.g., a donor (either living or cadaveric) or derived from an established cell strain or cell line. As an example of a method that can be used to obtain cells from a donor (e.g., a potential recipient of a bioscaffold graft), standard biopsy techniques known in the art may be employed. Alternatively, cells may be harvested from the subject, expanded/selected in vitro, and reintroduced into the same subject (i.e., autogeneic).

In some embodiments, cells are administered in a therapeutically effective amount. The therapeutically effective dosage of cells will vary somewhat from subject to subject, and will depend upon factors such as the age, weight, and condition of the subject and the route of delivery. Such dosages can be determined in accordance with procedures known to those skilled in the art. In general, in some embodiments, a dosage of \(1\times10^5\), \(1\times10^6\) or \(5\times10^6\) up to \(1\times10^7\), \(1\times10^8\) or \(1\times10^9\) cells or more per subject may be given, administered together at a single time or given as several subdivided administrations. In other embodiments, a dosage of between \(1\text{–}100\times10^8\) cells per kilogram subject body weight can be given, administered together at a single time or given as several subdivided administration. Of course, follow-up administrations may be given if necessary.

Cells may be administered according to some embodiments to achieve a target hematocrit range. The ideal or target hematocrit range may vary from subject to subject, depending upon, e.g., specific comorbidities. In some embodiments the target hematocrit is from 30-40%, in some embodiments the target hematocrit is from 33-
38%, and in some embodiments the target hematocrit is from 33-36%. Upon administration of cells according to the present invention, hematocrit may be measured and, if desired or necessary, corrected by, e.g., further implantation of cells and/or other methods known in the art (e.g., supplementing with recombinant EPO). Other methods of treatment for anemia and/or renal disease may be used in conjunction with the methods of treatment provided herein, for example, an adapted protein-caloric intake diet.

In further embodiments, if desired or necessary, the subject may be administered an agent for inhibiting transplant rejection of the administered cells, such as rapamycin, azathioprine, corticosteroids, cyclosporin and/or FK506, in accordance with known techniques. See, e.g., R. Calne, U.S. Patent Nos. 5,461,058, 5,403,833 and 5,100,899; see also U.S. Patent Nos. 6,455,518, 6,346,243 and 5,321,043. Some embodiments use a combination of implantation and immunosuppression, which minimizes graft rejection. The implantation may be repeated as needed to create an adequate mass of transplanted tissue.

The present invention is explained in greater detail in the following non-limiting Examples.

EXAMPLES

Anemia is an inevitable outcome of chronic renal failure due to the kidney's decreased ability to produce erythropoietin (EPO) by peritubular interstitial cells. We investigated whether supplementation of erythropoietin producing cells would be a possible treatment option for renal failure-induced anemia by examining the feasibility of selecting and expanding erythropoietin producing cells for cell-based therapy.

The following examples demonstrate that EPO producing cells are present in renal cells harvested from mouse and rat kidneys. In addition, cells isolated and expanded using the methods described below include cells expressing EPO at every culture stage examined. Further, the actual percentage of cells expressing the EPO marker in culture was consistent with the cell population present in normal kidney tissues (see Yamaguchi-Yamada et al., J Vet Med Sci, 67: 891, 2005; Sasaki et al., Biosci Biotechnol Biochem, 64: 1775, 2000; Krantz, Blood, 77: 419, 1991).

Example 1. Expansion of Renal Cell Primary Cultures. Renal cells from 7-10 day old mice C57BL/6 were culture expanded. Minced kidney (1 kidney of mouse)
was placed into a 50cc tube with 15ml of collagenase/dispase (0.2mg/ml). The kidney tissue fragments were incubated in a 37°C shaker for 30 min with collagenase/dispase mix (0.2mg/ml; 15ml). Sterile PBS with Gelatin (20ml), was added (with Gelatin (DIFCO) 2mg/ml) to the digestion solution. The mixture was filtered thorough a 70 micron filter to remove undigested tissue fragments. The collected solution was mixed well (being careful not to make air bubbles), and divided into two 50cc tubes. The tubes were centrifuged at 1000(-1500) RPM for 5 min. The supernatant was discarded and the pellet of each tube was resuspended in 3ml of KSFM medium. DMEM medium (10% FBS, 5ml P/S) is used for stromal cells, and KSFM with BPE, EGF, 5ml antibiotic-antimycotic, 12.5ml FBS (Gemini Bio-Product, 2.5%), Insulin Transferrin Selenium (Roche) (50mg for 5L medium) with BPE and EGF for epithelial components. P/S or antibiotic-antimycotic (GIBCO) may also be added. Each tissue was seeded on to a 25mm plate and medium was added (total 3ml).

Cells were maintained by changing the medium the next day, and then every 2 days depending on the cell density. Cells were passaged when they were 80-90% confluent by detachment using trypsin/EDTA and transferred to other plates with the following steps: 1) Remove medium. 2) Add 10 ml PBS/EDTA (0.5 M) for 4 minutes. Confirm the separation of cell junctions under a phase contrast microscope. 3) Remove PBS/EDTA and add 7 ml Trypsin/EDTA. 4) Add 5 ml medium when 80-90% of the cells lift under microscope. 5) Aspirate the cell suspension into a 15 ml test tube. 6) Centrifugue the cells at 1000 rpm for 4 minutes. 7) Remove the supernatant. 8) Resuspend cells in 5 ml of medium. 9) Pipet out 100 µl of the cell suspension and perform trypan blue stain for viability assay. 10) Count the number of cells on hemocytometer. 11) Aliquot the desired number of cells on the plate and make the volume of medium to a total of 10ml. 12) Place the cells in the incubator.

Alternatively, the following protocol was used. Kidneys from 10 day old male C57BL/6 mice were collected in Krebs buffer solution (Sigma Aldrich, St. Louis, MO USA) containing 10% antibiotic/antimycotic (Gibco Invitrogen, Carlsbad, CA USA) to avoid risk of contamination. The kidneys were immediately transported to a culture hood where the capsule was removed. The medullary region of the kidney was removed, and only the cortical tissue was used to isolate cells that had been previously identified as EPO producing cells (Maxwell et al., Kidney International, 44: 1149,
1993). The kidney tissue was minced and enzymatically digested using Liberase Blendzyme (Roche, Mannheim, Germany) for 25 minutes at 37 degrees Celsius in a shaking water bath. The supernatant was removed and the cell pellet was passed through a 100 μm cell strainer to obtain a single cell suspension for culture.

Subsequently, the cells were plated at a density of 5x10^5 cells/ml in 10 cm tissue culture treated plates filled with culture media. The culture media consisted of a mixture of keratinocyte serum-free medium (KSFM) and premixed Dulbecco’s Modified Eagle’s Medium (DMEM) at a ratio of 1:1. The premixed DMEM media contained ¼ DMEM and ¼ HAM’s F12 nutrient mixture supplemented with 10% fetal bovine serum (FBS), 1% Penicillin/Streptomycin, 1% glutamine 100x (Gibco), 1 ml of 0.4μg/ml hydrocortisone, 0.5 ml of a 10^{-10} M cholera toxin solution, 0.5 ml of a 5 mg/ml insulin solution, 12.5 ml/500ml of a 1.2 mg/ml adenine solution, 0.5 ml of a 2.5 mg/ml transferrin+0.136 mg/ml triiodothyronine mixture, and 0.5ml of a 10μg/ml epidermal growth factor (EGF) solution. All tissue culture reagents were purchased from Sigma-Aldrich (St. Louis, MO USA) unless otherwise stated. The cells were incubated at 37°C under 5% CO₂ with medium change every 3 days, and the cells were subcultured for expansion at a ratio of 1:3 when confluent.

**Example 2. Characterization for EPO Production.** The cells from early passages (1, 2 and 3) were characterized for EPO expression using immunocytochemistry and western blot analysis with specific antibodies (rabbit polyclonal anti-EPO antibodies, sc-7956, Santa Cruz Technologies, Santa Cruz, California).

Renal cells were plated in 8-well chamber slides at a density of 3000 cells per well. The cells were incubated at 37°C under 5% CO₂ for 24 h to allow attachment. This was followed by fixation with 4% paraformaldehyde for 10 minutes at room temperature. Permeabilization of cell membranes was performed by adding 0.1% Triton-X 100 in PBS for 3 minutes at room temperature. Cells were then incubated in goat serum for 30 minutes at room temperature. After washing, cells were incubated with the primary antibodies for 1h (1:50) at room temperature. Cells were washed a second time and biotinylated goat polyclonal anti-rabbit antibodies (polyclonal anti rabbit IgG, Vector Laboratories, Inc., Burlingame, California) (1:200) were added, followed by incubation at room temperature for 45 minutes. Chromogenic detection of
EPO followed a final washing step and was performed using the Vector ABC kit according to the manufacturer’s instructions (Vector Laboratories, Inc., Burlingame, California). Slides without the primary antibodies served as internal negative controls, and normal mouse renal tissue served as the positive control.

Renal cells in culture showed multiple phenotypes under the microscope. The cells reached confluency within 7 to 10 days of plating. Many of the cells observed in the first 3 passages after isolation from the kidney stained positively for EPO, as compared to the negative controls, which showed no background or nonspecific staining (Figure 2), which indicated that the observed staining was likely due to the presence of EPO in the cultures. The number of cells that stained positively for EPO remained constant throughout the 3 passages studied, even when phenotypic changes were observed in the culture during the same time period. Immunohistochemical staining of kidney tissue indicated a similar amount of EPO expression as that found in cultured cells (Figure 3).

The number of cells expressing EPO decreased slightly with subsequent passages (Figure 4). This is most likely due to the increased number of passages and loss of cells/function over time and manipulation. However, the relative percentage appears to remain stable after the first passage.

EPO expression was also confirmed by western blot, shown in Figure 5.

**Example 3. Mouse and Rat Renal Cell Characterization.** FACS analysis was used to quantify the number of EPO-producing cells in the established renal cell cultures at each passage (1-3 passages). The cells were collected by trypsinization and centrifugation, resuspended in media, and passed through a 70 μm cell strainer to ensure a single cell suspension. After counting the cells, they were spun down and resuspended in PBS at 5-7.5 x10^5 cells/ tube to remove FBS from the cells. The cells were fixed with 2% formaldehyde for 10 minutes at 4°C and permeabilized using 100% methanol for 10 minutes at room temperature. Subsequently, the cells were resuspended in 3% goat serum in PBS followed by incubation with the rabbit anti-EPO primary antibody sc-7956 (Santa Cruz Biotechnology, Santa Cruz, California) for 45 minutes on ice. Cells were washed twice with 3% goat serum in PBS prior to incubation with fluorescein isothiocyanate (FITC)-conjugated goat anti-rabbit secondary antibodies for 1 hour. The cells were then washed thoroughly with 3% serum.
in PBS and transferred to the FACS machine (FACS Calibur E6204, Becton-Dickinson, Franklin Lakes, New Jersey).

Fluorescent activated cell sorting experiments demonstrated that 44% of passage 1 (P1) cells were EPO positive. This percentage increased to 82% at passage 2 (P2), and then dropped back to 42% at passage 3 (P3). This may indicate that, during the first few days of culture, proliferation of EPO-producing cells and/or upregulation of EPO gene expression occurs in response to the lower oxygen concentration in the media compared to normal living tissue. These responses could then normalize over the next few days, resulting in numbers of EPO-producing cells that are close to those found in renal tissue (Figure 6, top row).

The FACS data demonstrate the maintenance of EPO expression over several passages. It should be noted that there was a surge in the number of cells expressing EPO (82%) in the passage 2 culture, which was confirmed by several repeat experiments. Though not wishing to be bound to any particular theory, one possible explanation for this phenomenon could be that EPO expression is an inherent trait of all renal cells that can be turned on and off as needed. In this case, following the abrupt change in survival conditions between the body and the culture plate, the cells may have been driven to express EPO momentarily until stabilization of the culture occurred. Consistent with this, the EPO surge was quickly reversed and passage 3 analyses showed a lower percentage of EPO producing cells (42%).

Mouse cell characterization by immunofluorescence confirmed EPO expression (Figure 7A). The population of cells was positive for the kidney cell markers GLEPP1 and Tamm Horsfall (Figure 7B).

Rat cell passages 0, 1 and 2 were also analyzed for EPO production using fluorescence activated cell sorting (FACS) (Figure 6, bottom row). Cultured rat cells had various cell morphologies and were positive for GLEPP1 and Tamm Horsfall kidney cell markers (Figure 8).

**Example 4. Exposure of EPO Producing Cultures to Hypoxic Conditions.**

While maintenance of phenotypic characteristics is essential during cell expansion stages, a critical component that ensures the success of cell therapy is the ability of EPO producing cells to regulate and maintain normal EPO levels. EPO belongs to the hematopoietic cytokine family, and it controls erythropoiesis in bone marrow, and
regulates the proliferation, differentiation and survival of erythroid progenitor cells through EPO receptor (EPOR)-mediated signal transduction. EPO is largely produced in the kidney, and when this organ fails, EPO production falls, leading to anemia. EPO expression in the body depends largely on the oxygen tension in the environment surrounding the cells capable of producing EPO. Factors influencing oxygen levels include lack of oxygen in the ambient air and decreased renal blood flow.

To determine whether the EPO expressing cells in culture could respond to changing oxygen levels, an experiment was performed in which the cells were serum-starved for 24 hours followed by exposing them to various levels of oxygen in vitro. Lewis rat kidney cells and HepG2 (human hepatocellular liver carcinoma cell line) cells were cultured under normal and hypoxic conditions, and EPO production was assessed and confirmed by western blot of cells. EPO presence in the culture medium was also measured and confirmed by analyzing the supernatants from cultured renal cells under normoxic and hypoxic conditions with the double antibody sandwich enzyme-linked immunosorberbent assay using a Quantikine® IVD® Erythropoietin ELISA kit (R&D Systems®, Minneapolis, Minnesota).

The cells were placed in serum free media for 24 hours prior to the experiment. The plates were then transferred to a hypoxic chamber and exposed to different hypoxic conditions (1%, 3%, 5%, and 7% oxygen). HepG2 cells were used as positive controls, as they have been previously reported to produce high levels of EPO in culture (Horiguchi et al., Blood, 96: 3743). EPO expression by HepG2 was confirmed by western blot (Figure 9). All cells were harvested in lysis buffer containing NP-40. Protein concentration in each sample was measured using a Bio-Rad protein assay. 40 μg total protein was run out on a 10% acrylamide gel using SDS-PAGE. Proteins were then transferred onto a PVDF membrane (Millipore Corp.). Detection of β-actin expression in the lysates was used as the loading control. EPO antibody (rabbit polyclonal sc-7956, Santa Cruz Biotechnology) was used at 1:200 and the secondary antibody (goat anti-rabbit 7074, Cell Signaling Technology, Beverly, Massachusetts) was used at 1:2000. To measure the amount of EPO secreted into the media by the primary renal cultures, the media was collected and concentrated down to 500ul using an Amicon Ultra centrifugal filter device (Millipore Corporation, Billerica, Massachusetts). Samples of this media were run on a 10% polyacrylamide gel. EPO
antibody (rabbit polyclonal sc-7956, Santa Cruz Biotechnology) was used at 1:100 and the secondary antibody (goat anti-rabbit 7074, Cell Signaling Technology; Beverly, MA, USA) was used at 1:2000.

Western blotting showed a slight increase in the EPO expression in the cell lysate after hypoxia (Figure 10). These results, however, were not seen when media concentrates were used to measure EPO (Figure 11). The media testing indicated that all media concentrates (hypoxic and normoxic conditions) contained the same low amount of EPO.

Alternatively, total protein lysates were prepared from rat renal primary cells at passages 1 and 2. Plates from normoxic samples (NC), samples in 3%02 and 7%O2 were processed and Run on 10% SDS-PAGE. The KNRK cell line was used as positive control. Results are shown in Figure 12.

Without wishing to be bound by any particular theory, this may indicate that 24 hours might not be enough time for secreted EPO levels to rise to a level that is detectable by western blot. It is likely that a longer exposure time would be required for the cells to begin to secrete EPO, as de novo protein production may take several hours to become apparent. Therefore the following experiment was performed, in which cells were placed in hypoxic conditions for 24, 48 and 72 hours.

Primary cultured cells from Lewis rats were raised close to confluency at each passage on 10cm plates. The cells were placed in a hypoxic chamber (1% O2) for 24, 48 or 72 hrs. Following hypoxia incubation, the media was collected and concentrated with a 10K molecular weight cutoff Amicon Ultra centrifugal device (Millipore). 40μg of total protein was then loaded on a 10% Polyacrylamide gel. KNRK cells were used as a positive control. Results are shown in Figure 13.

In summary, all experiments indicated that the EPO levels in primary culture cells were greater than or equal to those measured in the HepG2 positive controls, and the EPO producing cells are able to respond to changing environment.

Example 5. Administration of EPO Producing Cells in vivo. To determine whether EPO producing cells survive and form the tissues in vivo, renal cells mixed in collagen gel were implanted subcutaneously in athymic mice at concentrations of 1 x10^6 and 5 x10^6 followed by retrieval at 14 and 28 days after implantation for analysis.
Cells at different passages from 1-5 were used. The cells were suspended in a collagen gel for easy injection (concentration: 0.1mg/ml).

Histologically, the retrieved implants showed that surviving renal cells continue expressing EPO proteins, confirmed immunohistochemically using EPO specific antibodies (Figure 14).

These results demonstrate that EPO producing renal cells grown and expanded in culture stably expressed EPO in vivo. Thus, EPO producing cells may be used as a treatment option for anemia caused by chronic renal failure.

Example 6. Analysis of EPO Expression with Real Time PCR. Real time PCR was performed to assess rat cell expression of EPO in response to hypoxic conditions.

To test the effect of culture media, cells grown in either KSFM and DMEM were exposed to hypoxic conditions (3% O₂). Renal primary cells (passage 0) were grown to 80% confluency in 10cm plates. Three plates of cells were grown with either serum free KSFM or DMEM and placed in a hypoxic chamber at 3% O₂. After 24 hrs, samples were processed for total RNA and cDNA synthesis. Real time PCR was done in triplicate, and samples were quantified relative to normoxic sample. Results are shown in Figure 15.

Rat kidney culture EPO expression was compared with real time PCR across 24, 48 and 72 hours. Renal primary cells (passages 0 and 2) were grown to 80% confluency in 10cm plates. Cells were then grown in serum free KSFM and placed in a hypoxic chamber at 1% O₂. After 24, 48 or 72 hours, samples were processed for total RNA and cDNA synthesis. Real time PCR was done in triplicate, and samples were quantified relative to normoxic sample. Results are shown in Figure 16.

Testing timepoints for up to 24 hours, renal primary cells (passage 0) were grown to 80% confluency in 10cm plates. Cells were then placed in a hypoxic chamber at 1% O₂ for up to 24 hours. Samples were then processed for total RNA and cDNA synthesis. Real time PCR was run in triplicate, and samples were quantified relative to normoxic sample. Results are shown in Figure 17.

Example 7. Expansion of Human Kidney Cells. The growth and expandability of primary human kidney cells were also demonstrated using the media and conditions described above. Cultures from passages 2, 4, 7 and 9 are shown in
Figure 18. It was demonstrated that human primary renal cells can be maintained through twenty doublings (Figure 19). Human kidney cell cultures were characterized for EPO and GLEPP1 expression (Figure 20).

Example 8. Human Kidney Cell Delivery Via Collagen Injection. Human renal cells mixed in collagen gel were implanted subcutaneously in athymic mice as described above in Example 5. Collagen concentrations of 1mg/ml, 2mg/ml and 20mg/ml were compared. At 1 and 2 mg/ml, the in vivo volume disappeared after administration. At 20 mg/ml, the in vivo injection volume was maintained, and neovascularization was seen Figure 21. Histology confirmed that EPO expressing tissue was formed in vivo (Figure 22).

Example 9. EPO Producing Cell Selection with Magnetic Cell Sorting. Cells are selected for EPO production using magnetic cell sorting. A single-cell suspension is isolated using a standard preparation method. After preparation of single-cell suspension, count the total number of the cells and centrifuge cell samples to obtain a pellet. Block the cells with 10% of goat serum (of animal where the secondary antibody is made) for 10 minutes. Add 1 or 2 mL of the blocking solution. After 10 minutes of centrifugation, resuspend the cells in the primary antibody for EPO (use 1μg of the primary antibody/ million of cells). Typically, label for 15 minutes at 4–8 °C is sufficient. Wash the cells twice to remove any unbound primary antibody with 1–2 mL of buffer per $10^7$ cells and centrifuge at 300×g for 10 minutes. After two successive washes, the pellet is resuspended in 80 μL of PBS (0.5% of BSA and 2 mM of EDTA, pH 7.2) per $10^7$ cells. Add 20 μL of Goat Anti-Rabbit MicroBeads per $10^7$ cells. Mix well and incubate for 15 minutes at 4–8 °C. Wash the cells twice by adding 1–2 mL of buffer per $10^7$ cells and centrifuge at 300×g for 10 minutes. Pipette off supernatant completely. Resuspend up to $10^8$ cells in 500 μL of buffer (Note: For higher cell numbers, scale up buffer volume accordingly; for depletion with LD Columns, resuspend cell pellet in 500 μL of buffer for up to 1.25×108 cells). Proceed to magnetic cell separation.

Note: Work fast, keep cells cold, and use pre-cooled solutions. This will prevent capping of antibodies on the cell surface and non-specific cell labeling. Volumes for magnetic labeling given below are for up to $10^7$ total cells. When working with fewer than $10^7$ cells, use the same volumes as indicated. When working with
higher cell numbers, scale up all reagent volumes and total volumes accordingly (e.g. for $2 \times 10^7$ total cells, use twice the volume of all indicated reagent volumes and total volumes). Working on ice may require increased incubation times. Higher temperatures and/or longer incubation times lead to nonspecific cell labeling.

The foregoing is illustrative of the present invention, and is not to be construed as limiting thereof. The invention is defined by the following claims, with equivalents of the claims to be included therein.

Comprises/comprising and grammatical variations thereof when used in this specification are to be taken to specify the presence of stated features, integers, steps or components or groups thereof, but do not preclude the presence or addition of one or more other features, integers, steps, components or groups thereof.
THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:

1. An isolated population of cells comprising differentiated peritubular interstitial cells harvested from mammalian kidney tissue and passaged in vitro, wherein at least 20% or more of the cells of said population produce erythropoietin (EPO) under normoxic conditions without manipulation by an exogenous chemical that stimulates the production of EPO.

2. The population of cells according to claim 1, wherein at least 40% or more of the cells of said population produce EPO.

3. The population of cells according to claim 1 or 2, wherein said population further comprises endothelial cells of the kidney.

4. The population according to any one of claims 1-3, wherein said population has been passaged more than 3 times.

5. The population of cells according to claim 1, subject to the proviso that said cells are not transfected with an exogenous DNA encoding a polypeptide.

6. A composition comprising the population of cells according to any one of claims 1-5 and a pharmaceutically acceptable carrier.

7. A method of producing an isolated population of erythropoietin (EPO) producing cells, said method comprising the steps of:
   providing differentiated mammalian kidney cells; and
   passaging said differentiated kidney cells, wherein at least 20% or more of said cells produce EPO under normoxic conditions without manipulation by an exogenous chemical that stimulates the production of EPO after said passaging;
   thereby producing an isolated population of EPO producing cells.

8. The method of claim 7, wherein said passaging step comprises growth of differentiated kidney cells in a medium comprising insulin transferrin selenium (ITS).

9. The method of claim 8 or 9, wherein said differentiated kidney cells of said providing step further comprises endothelial cells of the kidney.
10. The method of any one of claims 7-9, subject to the proviso that said population of EPO producing cells are not transfected with an exogenous DNA encoding a polypeptide.

11. A method of treating a kidney disease resulting in decreased erythropoietin (EPO) production in a patient in need thereof, said method comprising:

   providing a composition comprising an isolated population of EPO producing cells in a pharmaceutically acceptable carrier, wherein at least 20% or more of said cells produce EPO without manipulation by an exogenous chemical that stimulates the production of EPO; and

   administering said composition to said patient, whereby said EPO producing cells produce EPO in vivo.

12. The method of claim 11, wherein said pharmaceutically acceptable carrier comprises a collagen gel.

13. The method of claim 11 or 12, wherein said administering step is carried out by injecting said composition into the kidney or liver of said patient.

14. The method of claim 11 or 12, wherein said administering step is carried out by injecting or infusing said composition intravascularly.

15. The method of claim 11 or 12, where said administering step is carried out by infusing said composition into a portal vein of said patient.

16. The method of claim 11, wherein said pharmaceutically acceptable carrier comprises a biodegradable scaffold and said administering step is carried out by implanting said composition into the kidney of said patient.

17. The method of any one of claims 11-16, wherein said population of EPO producing cells comprise differentiated peritubular interstitial cells.

18. The method of any one of claims 11-17, subject to the proviso that said cells are not transfected with an exogenous DNA encoding a polypeptide.
19. The method of any one of claims 11-18, wherein said kidney disease is an anemia selected from the group consisting of: an anemia of renal failure, an anemia of end-stage renal disease, an anemia of chemotherapy, an anemia of radiation therapy, an anemia of chronic infection, an anemia of an autoimmune disease, an anemia of rheumatoid arthritis, an anemia of AIDS, an anemia of a malignancy, an anemia of prematurity, an anemia of hypothyroidism, an anemia of malnutrition, and an anemia of a blood disorder.

20. The method of claim 11 or 12, wherein said administering step is carried out by injecting or implanting said composition.

21. The method of any one of claims 11-20, wherein said EPO producing cells are human.

22. An isolated population of cells comprising differentiated human kidney cells harvested from human kidney tissue and passaged in vitro, wherein at least 20% or more of the cells of said population produce erythropoietin (EPO) under normoxic conditions without manipulation by an exogenous chemical that stimulates the production of EPO.

23. The population of cells according to claim 22, wherein said population consists essentially of said differentiated human kidney cells.

24. The population of cells according to claim 22 or 23, wherein said human kidney cells have been passaged in vitro from 1 to 20 times.

25. The population of cells according to claim 22 or 23, wherein said human kidney cells have been passaged in vitro at least 3 times.

26. The population of cells according to any one of claims 22-25, wherein said population comprises peritubular interstitial cells and endothelial cells of the kidney.

27. The population of cells according to any one of claims 22-26, subject to the proviso that said cells are not transfected with an exogenous DNA encoding a polypeptide.
28. A composition comprising the population of cells according to any one of claims 22-27 and a pharmaceutically acceptable carrier.

29. The composition of claim 28, wherein said carrier comprises collagen.

30. A method of treating anemia in a patient in need thereof, said method comprising: providing a composition comprising the population of cells according to claim 22; and administering said composition to said patient in an amount effective to treat said anemia.

31. The method of claim 30, wherein said administering step is carried out by injecting or implanting said composition into said patient.

32. The method of claim 30 or 31, wherein said anemia is selected from the group consisting of: an anemia of renal failure, an anemia of end-stage renal disease, an anemia of a chemotherapy, an anemia of a radiation therapy, an anemia of chronic infection, an anemia of an autoimmune disease, an anemia of rheumatoid arthritis, an anemia of AIDS, an anemia of a malignancy, an anemia of prematurity, an anemia of hypothyroidism, an anemia of malnutrition, and an anemia of a blood disorder.

33. The population of cells according to claim 1, wherein at least 60% or more of the cells of said population produce EPO.

34. The population of cells according to claim 22, wherein at least 40% or more of the cells of said population produce EPO.

35. The population of cells according to claim 22, wherein at least 60% or more of the cells of said population produce EPO.

36. The population of cells according to claim 1, wherein said cells express GLEPP1 and/or Tamm Horsfall kidney cell markers.

37. The population of cells according to claim 22, wherein said cells express GLEPP1 and/or Tamm Horsfall kidney cell markers.
38. The population of cells according to claim 1, wherein said at least 20% or more of the cells of said population produce EPO without manipulation by the introduction of an exogenous gene or by an exogenous chemical that stimulates the production of EPO.

39. The population of cells according to claim 22, wherein said at least 20% or more of the cells of said population produce EPO without manipulation by the introduction of an exogenous gene or by an exogenous chemical that stimulates the production of EPO.

40. The composition of claim 28, wherein said carrier comprises a hydrogel.

41. Use of an isolated population of cells in the manufacture of a medicament for the treatment of kidney disease in a subject, wherein said cells comprise differentiated peritubular interstitial cells harvested from mammalian kidney tissue and passaged in vitro, wherein at least 20% or more of the cells of said population produce erythropoietin (EPO) under normoxic conditions without manipulation by an exogenous chemical that stimulates the production of EPO.

42. An isolated population of cells according to any one of claims 1-5, 22-27 or 33-39, a composition according to any one of claims 6, 28, 29 or 40, a method according to any one of claims 7-21 or 30-32, or use according to claim 41, wherein said isolated population of cells produce EPO in vivo upon administration.

43. An isolated population of cells according to any one of claims 1-5, 22-27 or 33-39 or 42, a composition according to any one of claims 6, 28, 29 or 40 or 42, a method according to any one of claims 7-21 or 30-32 or 42, or use according to claim 41 or 42, substantially as hereinbefore described.

P32640AU00
Mechanism of Erythropoietin production

Renal interstitial peritubular cells detect low blood oxygen levels

Erythropoietin (EPO) secreted into the blood

EPO stimulates the proliferation and differentiation of erythroid progenitors into reticulocytes, and prevents apoptosis

More reticulocytes enter circulating blood

Increased oxygen delivery to tissues

Reticulocytes differentiate into erythrocytes, increasing the erythron size

Figure 1
EPO-producing population represents >50% of population from
P0 → P2
