PATENTS ACT 1952

COMPLETE SPECIFICATION.
COMMONWEALTH OF AUSTRALIA
PATENTS ACT 1982
DECLARATION IN SUPPORT OF CONVENTION OR NON-CONVENTION APPLICATION FOR A PATENT

34005/84

In support of the Application made for a patent for an invention entitled: "BRANCH OFF DEVICE FOR MULTI CORE OPTICAL FIBER AND PRODUCTION THEREOF"

Inventor(s):

1. Teunoe Nakahara of SUMITOMO ELECTRIC INDUSTRIES, LTD.
of No. 15, Kitahama 5-chome, Higashi-ku, Osaka-shi, Osaka-fu, Japan

2. (a) I am the actual inventor of the invention and the facts upon which the applicant is entitled to make this application are as follows: I am authorized by SUMITOMO ELECTRIC INDUSTRIES, LTD.

(b) Shunzo Suzuki, Ichiro Ogasawara and Yasuo Matsuda all of c/o Yokohama Works of Sumitomo Electric Industries, Ltd., No. 1, Taya-cho, Totsuka-ku, Yokohama-shi, Kanagawa-ken, Japan

The applicant for the patent to make this declaration on behalf.

Cross out whichever of paragraphs 1(a) or 1(b) does not apply.

The basic application as defined by Section 141 of the Act was made in Japan on the 11th day of October, 1983 by SUMITOMO ELECTRIC INDUSTRIES, LTD. in the manner in which applicant(s) title from inventor(s) and is made.

3. The basic application referred to in paragraph 3 of this Declaration was the first application made in a Convention country in respect of the invention the subject of the application.

Declared at Osaka, JAPAN this 13th day of September, 1984
SUMITOMO ELECTRIC INDUSTRIES, LTD.

Davies & Collison, Melbourne and Canberra.

Signature of declarant(s) (no attestation required)

Note: Initial all alterations.

Taunoe Nakahara, Representative Director
A device for branching off a multi core optical fiber and connecting each elemental optical fiber thereof with a corresponding single core optical fiber, which device comprises a plurality of cores surrounded by a cladding material, in which, at one end of the device, each core has substantially the same diameter as that of the elemental optical fiber to be connected and spatial configuration of the cores are substantially the same as that of the elemental optical fibers, at the other end of the device, each core has substantially the same diameter as that of the single optical fiber to be connected and the core center distance is the same as or slightly larger than the cladding diameter of the single optical fiber, and all the the cladding materials surrounding the cores of the device are integrated together.
3. A process for producing the branch off device of the invention, which comprises drawing a preform comprising cores having substantially the same ratio of a core distance between the adjacent cores to the core diameter as that in a multi core optical fiber to be connected therewith and substantially the same spatial configuration as those of the multi core optical fiber in such a way that the outer diameter of the preform periodically changes so that, at a portion of the drawn preform having the smallest diameter, each core has substantially the same diameter as that of an elemental optical fiber of the multi core optical fiber to be connected and spatial configuration of the cores are substantially the same as that of the elemental optical fibers and, at a portion of the drawn preform having the largest diameter, each core has substantially the same diameter as that of a single optical fiber to be connected and the core distance is the same as or slightly larger than the cladding diameter of the single optical fibers, and cutting the drawn preform at or near the portions having the smallest and largest sizes.

Complete specification for the invention entitled:
"BRANCH OFF DEVICE FOR MULTI-CORE OPTICAL FIBER
AND PRODUCTION THEREOF"

The following statement is a full description of this invention,
including the best method of performing it known to us:

-1-
BRANCH OFF DEVICE FOR MULTI CORE OPTICAL FIBER
AND PRODUCTION THEREOF

FIELD OF THE INVENTION

The present invention relates to a branch off device for a multi core optical fiber and a process for producing the same. More particularly, it relates to a device for branching off a multi core optical fiber and connecting its elemental optical fibers with a plurality of single core optical fibers.

BACKGROUND OF THE INVENTION

A multi core optical fiber has various structures including, for example, a flat structure as shown in Fig. 1A and a star-like structure as shown in Fig. 1B. In these structures, the multi core optical fibers are produced by fusing adjacent parts of claddings 2 surrounding cores 1 of the optical fibers to integrate them.

When the multi core optical fiber is used in a field of communication, it is essential to branch it off to connect each elemental optical fiber with a single optical fiber and in turn with a terminal device. However, the core size of the elemental optical fiber contained in the multi core optical fiber is smaller than that of the single core optical fiber, and the cladding diameter, namely the core center distance of the former is smaller than that of the latter. Therefore, it is impossible to directly connect the elemental optical fiber of the multi core optical fiber...
with the single core optical fiber since the distance between the adjacent core centers of the former is smaller than that of the latter.

Hitherto, the single core optical fiber is connected with one of the elemental optical fibers of the multi core optical fiber by heating and drawing the end 10 of the single core optical fiber 11 to be connected to decrease its diameter to the same size as that of the elemental optical fiber (see Fig. 2A), bundling several single core optical fibers (see Fig. 2B) and then fusing and connecting the bundled fibers with the multi core optical fiber.

In this connecting method, since the claddings of the single core optical fibers are not fused together, it is difficult to correctly arrange the drawn optical fibers in a desired configuration, and the bundled portions of the claddings contact each other and tend to be damaged on their surfaces which may deteriorate strength of the optical fibers.

SUMMARY OF THE INVENTION

One object of the invention is to provide a branch off device with which a multi core optical fiber comprising elemental optical fibers each having a smaller diameter and a cladding diameter than those of a single optical fiber is easily branched off to connect its elemental optical fibers with a plurality of the single core optical fibers with less insertion loss.
Another object of the invention is to provide a process for producing such the branch off device.

BRIEF DESCRIPTION OF THE DRAWINGS

Figs. 1A and 1B are each crosssectional view of a multi core optical fiber having a different configuration of the cores,

Fig. 2A is an elevation view of a single optical fiber one end of which is drawn,

Fig. 2B is an elevation view of a conventional branch off device comprising a bundle of drawn single core optical fibers,

Fig. 3 is an elevation view of a branch off device of the invention and shows how to connect it with a multi core optical fiber and a plurality of single core optical fibers,

Fig. 4 schematically shows the production of a branch off device of the invention,

Fig. 4A is a cross sectional view of a preform from which the branch off device of the invention is produced,

Fig. 5 is an elevation view of a drawn preform, and

Fig. 6 shows a relationship between drawing rate change in the production of the branch off device and resulting outer size change of the drawn preform.

DETAILED DESCRIPTION OF THE INVENTION

According to one aspect of the invention, there is provided a device for branching off a multi core optical
fiber and connecting each elemental optical fiber thereof with a corresponding single core optical fiber, which device comprises a plurality of cores surrounded by a cladding material, in which, at one end of the device, each core has substantially the same diameter as that of the elemental optical fiber to be connected and spatial configuration of the cores are substantially the same as that of the elemental optical fibers, at the other end of the device, each core has substantially the same diameter as that of the single optical fiber to be connected and the core center distance is the same as or slightly larger than the cladding diameter of the single optical fiber, and all the cladding materials surrounding the cores of the device are integrated together.

According to another aspect of the invention, there is provided a process for producing the branch off device of the invention, which comprises drawing a preform comprising cores having substantially the same ratio of a core distance between the adjacent cores to the core diameter as that in a multi core optical fiber to be connected therewith and substantially the same spatial configuration as those of the multi core optical fiber in such a way that the outer diameter of the preform periodically changes so that, at a portion of the drawn preform having the smallest size, each core has substantially the same diameter as that of an elemental optical fiber of the multi core optical fiber to be connected and spatial configuration of the cores
are substantially the same as that of the elemental optical fibers and, at a portion of the drawn preform having the largest size, each core has substantially the same diameter as that of a single optical fiber to be connected and the core distance is the same as or slightly larger than the cladding diameter of the single optical fibers, and cutting the drawn preform at or near the portions having the smallest and largest sizes.

Now, the present invention will be illustrated by making reference to the attached drawings.

Fig. 3 shows how to branch off the multi core optical fiber 5 and to connect each elemental optical fibers with a plurality of single core optical fibers 6 by making use of a tapered branch off device 7 of the invention. The branch off device 7 is positioned between the multi core optical fiber 5 and a plurality of the single core optical fibers 6, and thereby, each elemental optical fiber of the multi core optical fiber are branched off and connected with the corresponding single core optical fiber 6. The claddings 9 surrounding the cores 8 of the multi core optical fiber are fused and integrated together. The length of the tapered portion of the device varies with tolerance limit of tapering of the core 8 and maximum insertion loss of the device, and is preferably from about 2 to 70 cm, more preferably from 3 to 20 cm. Since the cladding materials of the device are integrated, it is not necessary to bundle the single core optical fibers to be connected. Thus, they are
not damaged and the whole system has improved strength. The core of the branch off device and the elemental optical fiber of the multi core optical fiber or the single optical fiber may be connected by a per se conventional method such as fusion bonding, butt welding or with a connector. Among them, the fusion bonding is most preferred.

Although the branch off device of the invention is used to branch off the flat type multi core optical fiber in the above description, it may be used to branch off a different type of the multi core optical fiber when it is formed so that the configuration of its cores corresponds to that of the elemental optical fiber.

In the production of the branch off device of the invention, a preform comprising cores having substantially the same ratio of the core distance between the adjacent cores to the core diameter as that in the multi core optical fiber to be connected therewith and substantially the same spatial configuration as those of the multi core optical fiber is drawn in such a way that the outer size of the preform periodically changes. At a portion of the drawn preform having the smallest size, each core has substantially the same diameter and distance as those of an elemental optical fiber of the multi core optical fiber to be connected and spatial configuration of the cores are substantially the same as that of the elemental optical fibers, and at a portion of the drawn preform having the largest size, each core has substantially the same diameter as that
of a single optical fiber to be connected and the core distance is the same as or slightly larger than the cladding diameter of the single optical fibers. Thereafter, the drawn preform is cut at or near the portions having the smallest and largest sizes to obtain the branch off device of the invention.

The periodical change in the size of the preform may be caused by changing a drawing or supplying rate of the preform or a drawing temperature. Among them, change of the drawing rate is most preferred since it has quickest response.

By making reference to the attached drawings, the production of the branch off device of the invention will be explained.

In Fig. 4, a preform 12 comprising cores having the same spatial configuration as that of the multi core optical fiber is heated in a drawing furnace 13 and drawn downwardly by a capstan 16. The size of the drawn preform 7 is measured by a measuring device 14, and then coated with plastic by a coating device 15. The drawn preform is pulled by the capstan 16, its size is again measured by a second measuring device 18 and then cut by a cutter 17. The value measured by the device 14 is fed back to the capstan 16 to adjust its rotating rate, namely the drawing rate of the preform so as to change the size periodically as designed. The size of the drawn preform is again measured by the second measuring device 18 and the measured value is fed to
the cutter 17 to cut the preform at or near the portions having the smallest and largest sizes to produce the branch off device of the invention.

The drawn preform comprises a plurality of cores 8 and has the largest size at the portions (a) and the smallest size at the portions (b) as shown in Fig. 5. The cores 8 are surrounded by the claddings 9 and the adjacent parts of the claddings are fused and integrated together. The preform is cut at the portions (a) and (b) to produce the branch off devices of the invention. The preform may be cut by damaging its surface with a knife, high power laser, etc. and bending it to apply tensile stress on it or by melt cutting it with high power laser.

As the drawing rate is changed in the form of a sine wave (a), a triangular wave (b) or a trapezoid wave (c) as shown in the upper figure in Fig. 6, the external size of the drawn preform changes as shown in the lower figure in Fig. 6. Among them, the sine wave is most preferred in view of accuracy of the size and the insertion loss.

Example

According to the invention, a branch off device having a shape shown in Fig 3 was produced. At the smaller end of the device, each core had a diameter of 28 micrometers and a distance between the adjacent core centers of 70 micrometers and, at the larger end, the core had a diameter of 50 micrometers and a distance between the adjacent core center of 125 micrometers. The length of the
device was 10 cm. With the smaller end of the device, was connected a flat type five core optical fiber each elemental optical fiber of which had a core diameter of 28 micrometers and a cladding diameter of 70 micrometers, and with the larger end, were connected five single core optical fibers each having a diameter of 50 micrometers and a cladding diameter of 125 micrometers by fusion bonding.

The insertion loss of the branch off device was measured. At the connection between the device and the multi core optical fiber, it was about 0.5 dB and at the connection between the device and the single optical fiber, nearly zero dB.

THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:

1. A device for branching off a multi core optical fiber and connecting each elemental optical fiber thereof with a corresponding single core optical fiber, which device comprises a plurality of cores surrounded by a cladding material, in which, at one end of the device, each core has substantially the same diameter as that of the elemental optical fiber to be connected and spatial configuration of the cores are substantially the same as that of the elemental optical fibers, at the other end of the device, each core has substantially the same diameter as that of the single optical fiber to be connected and the core center distance is the same as or slightly larger than the cladding diameter of the single optical fiber, and all the cladding materials surrounding the cores of the device are integrated together.

2. A device according to claim 1, which is used to branch of a flat type multi core optical fiber.

3. A process for producing the branch off device of the invention, which comprises drawing a preform comprising cores having substantially the same ratio of a core distance between the adjacent cores to the core diameter as that in a multi core optical fiber to be connected therewith and substantially the same spatial configuration as those of
the multi core optical fiber in such a way that the outer
diameter of the preform periodically changes so that, at a
portion of the drawn preform having the smallest diameter,
each core has substantially the same diameter as that of an
elemental optical fiber of the multi core optical fiber to
be connected and spatial configuration of the cores are
substantially the same as that of the elemental optical
fibers and, at a portion of the drawn preform having the
largest diameter, each core has substantially the same
diameter as that of a single optical fiber to be connected
and the core distance is the same as or slightly larger than
the cladding diameter of the single optical fibers, and
cutting the drawn preform at or near the portions having the
smallest and largest sizes.

4. A process according to claim 3, wherein the
preform is drawn in the form of a sine wave.
5. A device for branching off a multi core optical fiber and connecting each elemental optical fiber thereof with a corresponding single core optical fiber, substantially as hereinbefore described with reference to the drawings and/or example.

6. A process for producing a branch off device, substantially as hereinbefore described with reference to the drawings and/or example.

7. The steps or features disclosed herein or any combination thereof.
