**Title:** SUBSTITUTED BENZOPYRAN DERIVATIVES FOR THE TREATMENT OF INFLAMMATION

A class of benzopyran derivatives is described for use in treating cyclooxygenase-2 mediated disorders. Compounds of particular interest are defined by Formula (I'), wherein X, A1, A2, A3, A4, R, R'', R' and R'' are as described in the specification.
SUBSTITUTED BENZOPYRAN DERIVATIVES
FOR THE TREATMENT OF INFLAMMATION

FIELD OF THE INVENTION

This invention is in the field of anti-inflammatory pharmaceutical agents and specifically relates to compounds, compositions and methods for treating cyclooxygenase-2 mediated disorders, such as inflammation and inflammation-related disorders.

BACKGROUND OF THE INVENTION

Prostaglandins play a major role in the inflammation process and the inhibition of prostaglandin production, especially production of PGG₂, PGH₂ and PGE₂, has been a common target of antiinflammatory drug discovery. However, common non-steroidal antiinflammatory drugs (NSAIDs) that are active in reducing the prostaglandin-induced pain and swelling associated with the inflammation process are also active in affecting other prostaglandin-regulated processes not associated with the inflammation process. Thus, use of high doses of most common NSAIDs can produce severe side effects, including life threatening ulcers, that limit their therapeutic potential. An alternative to NSAIDs is the use of corticosteroids, which have even more drastic side effects, especially when long term therapy is involved.

Previous NSAIDs have been found to prevent the production of prostaglandins by inhibiting enzymes in the human arachidonic acid/prostaglandin pathway, including the enzyme cyclooxygenase (COX). The recent
discovery of an inducible enzyme associated with inflammation (named "cyclooxygenase-2 (COX-2)" or "prostaglandin G/H synthase II") provides a viable target of inhibition which more effectively reduces inflammation and produces fewer and less drastic side effects.

The references below that disclose antiinflammatory activity, show continuing efforts to find a safe and effective antiinflammatory agent. The novel benzopyran, dihydroquinoline, benzo thiopyran and dihydronapthalene derivatives disclosed herein are such safe and also effective antiinflammatory agents furthering such efforts. The substituted benzopyran, dihydroquinoline, benzo thiopyran and dihydronapthalene derivatives disclosed herein preferably selectively inhibit cyclooxygenase-2 over cyclooxygenase-1.

benzothiopyran carboxylates as starting material in the preparation of antiinflammatories.

However, compounds of the current invention have not been described as cyclooxygenase inhibitors.

In a tenth aspect, the present invention provides a pharmaceutical composition comprising a therapeutically-effective amount of a compound according to the first or second aspects of the present invention, or an isomer or pharmaceutically acceptable salt thereof, in association with at least one pharmaceutically-acceptable carrier, adjuvant or diluent.
Also included in the family of compounds of Formula I are the stereoisomers thereof. Compounds of the present invention can possess one or more asymmetric carbon atoms and are thus capable of existing in the form of optical isomers as well as in the form of racemic or nonracemic mixtures thereof. Accordingly, some of the compounds of this invention may be present in racemic mixtures which are also included in this invention. The optical isomers can be obtained by resolution of the racemic mixtures according to conventional processes, for example by formation of diastereoisomeric salts by treatment with an optically active base and then separation of the mixture of diastereoisomers by crystallization, followed by liberation of the optically active bases from these salts. Examples of appropriate bases are brucine, strychnine, dehydroabietylamine, quinine, cinchonidine, ephedrine, α-methylbenzylamine, amphetamine, deoxyphedrine, chloramphenicol intermediate, 2-amino-1-butanol, and 1-(1-naphthyl)ethylamine. A different process for separation of optical isomers involves the use of a chiral chromatography column optimally chosen to maximize the separation of the enantiomers. Still another available method involves synthesis of covalent diastereoisomeric molecules. The synthesized diastereoisomers can be separated by conventional means such as chromatography, distillation, crystallization or sublimation, and then hydrolyzed to deliver the enantiomerically pure compound. The optically active compounds of Formula I can likewise be obtained by utilizing optically active starting materials. These isomers may be in the form of a free acid, a free base, an ester or a salt. Additional methods for resolving optical isomers, known to those skilled in the art may be used, for example, those discussed by J. Jaques et al in Enantiomers.
Also included in the family of compounds of Formula I and I' are the amide protected acids thereof. Thus primary and secondary amines can be reacted with the chromene-3-carboxylic acids of Formula I and I' to form amides which can be useful as prodrugs. Preferred amines are heterocyclicamines, including optionally substituted aminothiazoles, optionally substituted amino-isoxazoles, and optionally substituted aminopyridines; aniline derivatives; sulfonamides; aminocarboxylic acids; and the like. Additionally, 1-acyldihydroquinolines can behave as prodrugs for the 1H-dihydroquinolines.

The term "pharmaceutically-acceptable salts" embraces salts commonly used to form alkali metal salts and to form addition salts of free acids or free bases. Examples of such inorganic acids are hydrochloric, hydrobromic, hydroiodic, nitric, carbonic, sulfuric and phosphoric acid. **SCHEME 1**

![Chemical structure diagram](image)
Synthetic Scheme 1 illustrates the general method for the preparation of a wide variety of substituted 2H-1-benzopyran derivatives 3 and 4. In step 1, a representative ortho-hydroxybenzaldehyde (salicylaldehyde) derivative 1 is condensed with an acrylate derivative 2 in the presence of base, such as potassium carbonate in a solvent such as dimethylformamide, to afford the desired 2H-1-benzopyran ester 3. An alternative base-solvent combination for this condensation includes an organic base such as triethylamine and a solvent such as dimethyl sulfoxide. In step 2 the ester is hydrolyzed to the corresponding acid, such as by treatment with aqueous base (sodium hydroxide) in a suitable solvent such as ethanol to afford after acidification the substituted 2H-1-benzopyran-3-carboxylic acid 4.

Synthetic Scheme 2 shows the general method for functionalizing selected 2H-1-benzopyrans. Treatment of the 2H-1-benzopyran carboxylic acid 4 or ester 3 with an electrophilic agent makes a 6-substituted 2H-1-benzopyran 5. A wide variety of electrophilic agents react selectively with 2H-1-benzopyrans 4 in the 6-position to provide new analogs in high yield. Electrophilic reagents such as halogen (chlorine or bromine) give the 6-halo derivatives. Chlorosulfonic acid reacts to afford the 6-position sulfonyl chloride that can further be converted to a sulfonamide or sulfone. Friedel-Crafts acylation of 4 provides 6-acylated 2H-1-benzopyrans in good to excellent yield. A number of other electrophiles can be used to selectively react with these 2H-1-benzopyrans in a similar
manner. A 6-position substituted 2H-1-benzopyran can react with an electrophilic reagent at the 8-position using similar chemistries to that described for electrophilic substitution of the 6-position. This yields an 2H-1-benzopyran which is substituted at both the 6 and 8 positions.

**SCHEME 3**

![Scheme 3 diagram](image)

Synthetic Scheme 3 illustrates a second general synthesis of substituted 2H-1-benzopyran-3-carboxylic acids which allows substitution at position 4 of the 2H-1-benzopyran. In this case a commercially or synthetically available substituted ortho-hydroxy acetophenone 6 is treated with two or more equivalents of a strong base such as lithium bis(trimethylsilyl)amide in a solvent such as tetrahydrofuran (THF), followed by reaction with diethyl
carbonate to afford the beta-keto ester 7. Ester 7 is
condensed with an acid chloride or anhydride in the presence
of a base such as potassium carbonate in a solvent such as
toluene with heat to afford 4-oxo-4H-1-benzopyran 8.
Reduction of the olefin can be accomplished by a variety of
agents including sodium borohydride (NaBH₄) in solvent
mixtures such as ethanol and tetrahydrofuran (THF), or by
use of triethylsilane in a solvent such as trifluoroacetic
acid, or by catalytic reduction using palladium on charcoal
and hydrogen gas in a solvent such as ethanol to yield the
new beta-keto ester 9 (two tautomeric structures shown).
Acylation of the oxygen of the ketone enolate in the
presence of a base such as 2,6-di-tert-butyl-4-
methylpyridine, an acylating agent such as
trifluoromethanesulfonyl anhydride, and using a solvent such
as methylene chloride yields the enol-triflate 10. Triflate
10 can be reduced with reagents such as tri-n-butyltin
hydride, lithium chloride and a palladium (0) catalyst such
as tetrakis(triphenylphosphine)palladium (0) in a solvent
such as tetrahydrofuran to yield 2H-1-benzopyran ester 11
where R'' is hydrogen. The ester 11 can be saponified with a
base such as 2.5 N sodium hydroxide in a mixed solvent such
as tetrahydrofuran-ethanol-water (7:2:1) to yield the
desired substituted 2H-1-benzopyran-3-carboxylic acid.
To incorporate a carbon fragment R'' one can treat
triflate 10 with reagents known to undergo "cross-coupling"
chemistries such as tributylethenyltin , lithium chloride
and a palladium(0) catalyst such as
tetrakis(triphenylphosphine)palladium (0) in a solvent such
as tetrahydrofuran to yield 2H-1-benzopyran ester 11 where
R' is a vinyl moiety. The ester 6 can be saponified with a
base such as 2.5 N sodium hydroxide in a mixed solvent such
as tetrahydrofuran-ethanol-water (7:2:1) to yield the
desired 4-vinyl-2H-1-benzopyran-3-carboxylic acid (12, R'' =
CH₂CH-). Similarly triflate 10 can be converted under
similar conditions using tri-n-butylphenyltin to 2H-1-
benzopyran where R' = phenyl and by hydrolysis of the ester
converted to the carboxylic acid 12 where $R' = \text{phenyl}$.

Using a similar strategy, substituents which be incorporated as substituent $R'$ can be substituted olefins, substituted aromatics, substituted heteroaryl, acetylenes and substituted acetylenes.

**SCHEME 4**

![SCHEME 4](image)

Synthetic Scheme 4 shows an alternative general procedure for the preparation of 4-oxo-4H-1-benzopyran 8. Treatment of an ortho-fluorobenzoyl chloride with an appropriately substituted beta-keto ester 14 with a base such as potassium carbonate in a solvent such as toluene provides 4-oxo-4H-1-benzopyran 8. 4-oxo-4H-1-benzopyran 8 can be converted to 2H-1-benzopyran 12 as described in Scheme 3.

**SCHEME 5**

![SCHEME 5](image)

$Y = \text{Br, I, CF}_3\text{SO}_3$

Synthetic Scheme 5 shows a general method for substitution of the aromatic ring of the 2H-1-benzopyran. This can be accomplished through organo-palladium mediated "cross-coupling" chemistries using a palladium (0) catalyst to couple benzopyran 15 at position $Y$, where $Y$ is iodide, bromide or triflate, with an acetylene, olefin, nitrile, or aryl coupling agent. Substituted acetylenes as the coupling agent will provide the corresponding substituted acetylene.
Substituted aryl moieties can be incorporated using aryloboronic acids or esters; nitriles can be incorporated by use of zinc (II) cyanide. The resulting ester 16 can be converted to carboxylic acid 17 as described in Scheme 1.

Another approach to substitution of the aryl moiety of the benzopyran 15 is to convert Y, where Y is iodide or bromide, to a perfluoroalkyl moiety. Exemplary of this transformation is the conversion of 15 (Y = iodide) to 16 (R' = pentafluoroethyl) using a potassium pentafluoropropionate and copper (I) iodide in hexamethylphosphoramide (HMPA). The resulting ester 16 can be converted to carboxylic acid 15 as described in Scheme 1.

A similar method adds substitution of the aromatic ring in dihydroquinoline-3-carboxylates. This can be accomplished through organopalladium couplings with aryl iodides, bromides, or triflates and various coupling agents (R. F. Heck, *Palladium Reagents in Organic Synthesis.* Academic Press 1985). When using a suitable palladium catalyst such as tetrakis(triphenyl-phospine)palladium(0) in this reaction, coupling agents such as alkynes provide disubstituted alkynes, phenyl boronic acids afford biphenyl compounds, and cyanides produce arylcyano compounds. A number of other palladium catalysts and coupling reagents could be used to selectively react with appropriately substituted dihydroquinoline-3-carboxylates in a similar manner.

**SCHEME 6**

![Scheme 6](image)

Synthetic Scheme 6 shows a general synthetic route for conversion of a commercially or synthetically available
substituted phenol into a substituted salicylaldehyde. Several different methods which utilize formaldehyde or a chemically equivalent reagent are described in detail below.

Reaction of an appropriately substituted phenol $\mathbf{18}$ in basic media with formaldehyde (or chemical equivalent) will yield the corresponding salicylaldehyde $\mathbf{1}$. The intermediate, ortho-hydroxymethylphenol $\mathbf{19}$, will under appropriate reaction conditions be oxidized to the salicylaldehyde $\mathbf{1}$ in situ. The reaction commonly employs ethyl magnesium bromide or magnesium methoxide (one equivalent) as the base, toluene as the solvent, paraformaldehyde (two or more equivalents) as the source of formaldehyde, and employs hexamethylphoramide (HMPA) or $N,N,N',N'$-tetramethylethylenediamine (TMEDA). (See: Casiraghi, G. et al., J.C.S.Perkin I, 1978, 318-321.) Alternatively an appropriately substituted phenol $\mathbf{18}$ may react with formaldehyde under aqueous basic conditions to form the substituted ortho-hydroxybenzyl alcohol $\mathbf{19}$ (See: a) J. Leroy and C. Wakselman, J. Fluorine Chem., 40, 23-32 (1988). b) A. A. Moshfegh, et al., Helv. Chim. Acta., 65, 1229-1232 (1982)). Commonly used bases include aqueous potassium hydroxide or sodium hydroxide. Formalin (38% formaldehyde in water) is commonly employed as the source of formaldehyde. The resulting ortho-hydroxybenzyl alcohol $\mathbf{19}$ can be converted to the salicylaldehyde $\mathbf{1}$ by an oxidizing agent such as manganese (IV) dioxide in a solvent such as methylene chloride or chloroform (See: R-G. Xie, et al., Synthetic Commun. 24, 53-58 (1994)).

An appropriately substituted phenol $\mathbf{18}$ can be treated under acidic conditions with hexamethylenetetramine (HMTA) to prepare the salicylaldehyde $\mathbf{1}$ (Duff Reaction; See: Y. Suzuki, and H. Takahashi, Chem. Pharm. Bull., 31, 1751-1753 (1983)). This reaction commonly employs acids such as acetic acid, boric acid, methanesulfonic acid, or trifluoromethanesulfonic acid. The source of formaldehyde commonly used is hexamethylenetetramine.
Synthetic Scheme 7 shows the Reimer-Tiemann reaction in which an commercially or synthetically available appropriately substituted phenol 18 will under basic conditions react with chloroform to yield a substituted salicylaldehyde 1 (See: Cragoe, E.J.; Schultz, E.M., U.S. Patent 3 794 734, 1974).

Synthetic Scheme 8 shows the conversion of a commercially or synthetically available appropriately substituted salicylic acid 21 to its respective salicylaldehyde 1 via an intermediate 2-hydroxybenzyl alcohol 19. Reduction of the salicylic acid 21 can be accomplished with a hydride reducing agent such as borane in a solvent such as tetrahydrofuran. Treatment of the intermediate 2-hydroxybenzyl alcohol 19 with an oxidizing agent such as manganese (IV) oxide in a solvent such as methylene chloride or chloroform provides salicylaldehyde 1.
Synthetic Scheme 9 illustrates a general synthetic method for preparation of a wide variety of substituted 2-(trifluoromethyl)-2H-1-benzothiopyran-3-carboxylic acids (25). In step 1, an appropriately commercially or synthetically available substituted thiophenol 22 is ortho-metallated with a base such as n-butyllithium employing TMEDA (N,N,N',N'-tetramethylethylenediamine) followed by treatment with dimethylformamide to provide the 2-mercaptobenzaldehyde 23. Condensation of the 2-mercaptobenzaldehyde 23 with an acrylate 2 in the presence of base provides ester 24 which can be saponified in the presence of aqueous base to afford the substituted 2H-1-benzothiopyran-3-carboxylic acids 25.
Synthetic Scheme 10 shows a method for preparing a substituted 2-mercaptobenzaldehyde from an appropriate commercially or synthetically available substituted salicylaldehyde. In step 1, the phenolic hydroxyl of salicylaldehyde \(1\) is converted to the corresponding O-aryl thiocarbamate \(26\) by acylation with an appropriately substituted thiocarbamoyl chloride such as \(\text{N,N-dimethylthiocarbamoyl chloride}\) in a solvent such as dimethylformamide using a base such as triethylamine. In Step 2, O-aryl thiocarbamate \(26\) rearranges to S-aryl thiocarbamate \(27\) when heated sufficiently such as to 200 °C using either no solvent or a solvent such as \(\text{N,N-dimethylaniline}\) (See: A. Levai, and P. Sebok, Synth. Commun., 22 1735-1750 (1992)). Hydrolysis of S-aryl thiocarbamate \(27\) with a base such as 2.5 N sodium hydroxide in a solvent mixture such as tetrahydrofuran and ethanol yields the substituted 2-mercaptobenzaldehyde \(23\) which can be converted to the substituted 2H-1-benzothiopyran-3-carboxylic acids \(25\) as described in Scheme 9.
Synthetic Scheme 11 illustrates the general method for the preparation of a wide variety of dihydroquinoline-3-carboxylic acid derivatives 30. $R^1$ represents the aromatic substitution of commercially and synthetically available 2-aminobenzaldehydes 28. The 2-aminobenzaldehyde derivative 28, where $R^1$ represents various substitutions, is condensed with an acrylate derivative 2 in the presence of base such as potassium carbonate, triethylamine, or diazabicyclo[2.2.2]undec-7-ene in solvents such as dimethylformamide to afford the dihydroquinoline-3-carboxylate esters 29. The ester 29 can be saponified to the corresponding acid, such as by treatment with aqueous inorganic base such as 2.5 N sodium hydroxide in a suitable solvent such as ethanol to afford after acidification the desired dihydroquinoline-3-carboxylic acid 30.
Synthetic Scheme 12 illustrates the preparation of dihydroquinoline-3-carboxylic acid 30 from 2-aminobenzoic acids 31. R² represents the aromatic substitution of commercially and synthetically available 2-aminobenzoic acids 31. Reduction of the representative 2-aminobenzoic acid 31 to the desired 2-aminobenzyl alcohol 32 was accomplished with a hydride reducing agent such as borane in a solvent such as tetrahydrofuran. Treatment of the desired 2-aminobenzyl alcohol 32 with an oxidizing agent such as manganese(IV) oxide in a solvent such as methylene chloride provides the representative 2-aminobenzaldehydes 28. (C. T. Alabaster, et al. J. Med. Chem. 31, 2048-2056 (1988)) The 2-aminobenzaldehydes were converted to the desired dihydroquinoline-3-carboxylic acid 30 as described in Scheme 11.
Synthetic Scheme 13 illustrates the general method for the preparation of a wide variety of dihydroquinoline-3-carboxylic acid derivatives 30 from isatins 33. $R^2$ represents the aromatic substitution of commercially and synthetically available isatins 33. A representative isatin 33 was treated with basic peroxide generated from hydrogen peroxide and a base such as sodium hydroxide to afford the desired representative 2-aminobenzoic acids 31. (M. S. Newman and M. W. Lougue, J. Org. Chem., 36, 1398-1401 (1971)) The 2-aminobenzoic acids 31 are subsequently converted to the desired dihydroquinoline-3-carboxylic acid derivatives 30 as described in synthetic Scheme 12.

**SCHEME 14**

![Scheme 14 Diagram](image)

Synthetic Scheme 14 is another general method for the preparation of dihydroquinoline-3-carboxylic acid derivatives 30. In step 1, an appropriate commercially or synthetically available substituted aniline 34 can be treated with an acylating reagent such as pivaloyl chloride.
yielding an amide 35. The ortho-dianion of amide 35 is prepared by treating amide 35 with organo-lithium bases such as n-butyllithium or tert-butyllithium in tetrahydrofuran at low temperature. The dianion is quenched with dimethylformamide to afford the acylated-2-amino-benzaldehydes 36. (J. Turner, J. Org. Chem., 48, 3401-3408 (1983)) Reaction of these aldehydes in the presence of bases such as lithium hydride with a acrylate followed by work up with aqueous inorganic bases and hydrolysis, such as by treatment with aqueous base (sodium hydroxide) in a suitable solvent such as ethanol affords, after acidification, a dihydroquinoline-3-carboxylic acid 30.

**SCHEME 15**

![Chemical Structure](image)

Synthetic Scheme 15 shows a general method for alkylation of the nitrogen of dihydroquinoline-3-carboxylate ester derivatives 29. The step involves treatment of dihydroquinoline-3-carboxylate ester derivatives 29 with alkyl halides such as iodoethane in the presence of phase transfer catalysts such a tetrabutylammonium iodide, and a base such as caustic (50% aqueous sodium hydroxide) in a solvent such as dichloromethane. These conditions afford the N-alkylated dihyrdoquinoline-3-carboxylate esters 37.
Saponification of 37 with aqueous base provides N-alkylated-dihydroquinoline-3-carboxylic acid derivatives 38.

6-Chloro-2-trifluoromethyl-2H-1-benzopyran-3-carboxylic acid

**Step 1. Preparation of ethyl 6-chloro-2-trifluoromethyl-2H-1-benzopyran-3-carboxylate.**

A mixture of 5-chlorosalicylaldehyde (20.02 g, 0.128 mole) and ethyl 4,4,4-trifluorocrotonate (23.68 g, 0.14 mole) was dissolved in anhydrous DMF, warmed to 60 °C and treated with anhydrous K$_2$CO$_3$ (17.75 g, 0.128 mole). The solution was maintained at 60 °C for 20 hours, cooled to room temperature, and diluted with water. The solution was extracted with ethyl acetate. The combined extracts were washed with brine, dried over anhydrous MgSO$_4$, filtered and concentrated in vacuo to afford 54.32 g of an oil. The oil was dissolved in 250 mL of methanol and 100 mL of water, whereupon a white solid formed that was isolated by filtration, washed with water and dried in vacuo, to afford the ester as a yellow solid (24.31 g, 62%): mp 62-64 °C. $^1$H NMR (CDCl$_3$/90 MHz) 7.64 (s, 1H), 7.30-7.21 (m, 2H), 6.96 (d, 1H, $J$ = Hz), 5.70 (q, 1H, $J$ = Hz), 4.30 (q, 2H, $J$ = 7.2 Hz), 1.35 (t, 3H, $J$ =7.2 Hz).

6-(Methylthio)-2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylic acid

Step 1. Preparation of 5-(methylthio)salicylaldehyde.

Ethyl magnesium bromide (38 mL of a 3.0 M solution in diethyl ether, 113.8 mmole) was chilled with an ice-water bath. To the chilled solution was added a solution of 4-(methylthio)phenol (15.95 g, 113.8 mmole) in diethyl ether (30 mL) over 0.15 hour during which time gas was evolved. The reaction was held at 0 °C for 0.5 hour, at room temperature for 0.5 hour, and the addition funnel replaced with a distillation head. Toluene (100 mL) was added and the diethyl ether was distilled out of the reactor. The reaction was cooled, toluene (250 mL) and hexamethylphosphoramide (HMPA) (19.8 mL, 20.4 g, 113.8 mmole) were added, and the resulting mixture was stirred for 0.25 hours. The distillation head was replaced with a condenser and paraformaldehyde (8.5 g, 284.4 mmole) was added. The reaction was heated to 90 °C for 3 hours. The reaction mixture was cooled to room temperature, was acidified with 1N HCl and the layers separated. The organic phase was washed with water, and with brine, dried over MgSO₄, filtered, and concentrated in vacuo to yield a solid. This solid was purified by silica chromatography (hexanes-ethyl acetate, 5:1) yielding the salicylaldehyde as a yellow
crystalline solid (6.01 g) of suitable purity to be used in
the next reaction without further purification.

**Step 2. Preparation of ethyl 6-(methylthio)-2-
(trifluoromethyl)-2H-1-benzopyran-3-carboxylate.**

5-Methylthiosalicylaldehyde (Step 1) (2.516 g, 14.96
mmole) was added to dimethylformamide (3.5 mL), potassium
carbonate (2.27 g, 16.45 mmole) and ethyl 4,4,4-
trifluorocrotonate (3.3 mL, 3.8 g, 22.4 mmole). The mixture
was heated to 65 °C for 3 h. The reaction was cooled to
room temperature, poured into H2O (50 mL), and extracted
with diethyl ether (2 X 75 mL). The combined ethereal
phases were washed with aqueous NaHCO3 solution (3 X 50 mL),
aqueous 2 N HCl solution (3 X 50 mL), and brine (3 X 50 mL),
dried over MgSO4, filtered, diluted with isooctane and
partially concentrated in vacuo causing the precipitation of
the ethyl ester (2.863 g, 60%) as a yellow powder: mp
87.8-89.6 °C This ester was of suitable purity to use
without further purification.

2H-1-benzopyran-3-carboxylic acid.**

carboxylic acid via a method similar to that described in

EXAMPLE 8

6-Chloro-7-(1,1-dimethylethyl)-(trifluoromethyl)-2H-1-benzopyran-3-carboxylic acid

Step 1. Preparation of 4-tert-butylsalicylaldehyde.

A five liter three-neck round bottom flask equipped with overhead mechanical stirrer and condenser was charged with trifluoroacetic acid (2.4 L). A mixture of 3-tert-butylphenol (412 g, 2.8 mole) and HMTA (424 g, 3.0 mole) was
added portion-wise causing an exotherm. With cooling, the temperature was maintained under 80 °C. The reaction was heated at 80 °C for one hour, then cooled, and water (2 L) added. After 0.5 hour additional water (4 L) was added and the mixture was extracted with ethyl acetate (6 L). The organic extract was washed with water and brine. The resulting organic phase was divided into 2 L volumes and each diluted with water (1 L), and solid NaHCO₃, added until the mixture was neutralized. The organic phases were isolated and combined, dried over MgSO₄, filtered and concentrated in vacuo yielding an oil. This oil was distilled at 95 °C (0.8 mm) yielding the desired salicylaldehyde as an oil (272.9 g, 56 %) which was of sufficient purity to be used without further purification.

Step 2. Preparation of ethyl 7-(1,1-dimethylethyl)-2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylate.

A one liter three-neck flask was charged with 4-tert-butylsalicylaldehyde (Step 1)(100.0 g, 0.56 mole), dimethylformamide (110 mL), and potassium carbonate (79.9 g, 0.58 mole) causing the temperature of the mixture to rise to 40 °C. Ethyl 4,4,4-trifluorocrotonate (118.0 g, 0.70 mole) in dimethylformamide (110 mL) was added and the mixture heated to 60 °C at which time the reaction temperature rose to 70 °C. The reaction was cooled to 60 °C, maintained at 60 °C (with added heating) for 8.5 hours and cooled to room temperature. Ethyl acetate (600 mL) and 3 N HCl (600 mL) were added, mixed, and the layers separated. The aqueous phase was extracted with ethyl acetate and the organic phases were combined. The combined organic phases were washed with brine-water (1:1), brine, dried over MgSO₄, filtered and concentrated in vacuo, yielding a semi-solid. Hexane (600 mL) was added with mixing and the mixture was filtered. The filtrate was washed with brine, dried over MgSO₄, filtered and concentrated in vacuo yielding a solid. This solid was dissolved in hot ethanol (600 mL). Water
(190 mL) was added which induced crystallization. Filtration of the mixture and drying of the product provided the desired ester as a crystalline solid (131.3 g, 71%): mp 91.0-94.9 °C. This material was of suitable purity to be used in subsequent steps without further purification.

**Step 3. Preparation of ethyl 6-chloro-7-(1,1-dimethylethyl)-2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylate.**

A one liter three-neck flask equipped with mechanical stirrer and gas inlet tube was charged with the ester (Step 2) (100 g, 0.3 mole) and acetic acid (300 mL). While cooling (water bath) the reaction mixture, chlorine gas (37.6 g, 0.53 mole) was added which caused the temperature to rise to 48 °C. After stirring for two hours, the reaction was cooled in an ice-water bath to 15 °C. Zinc powder (19.5 g, 0.3 mole) was added in one portion which caused the temperature to rise to 72 °C. After cooling to room temperature additional zinc powder (5.0 g, 0.08 mole) was added and the mixture was stirred for 0.5 hour longer. The crude mixture was filtered through diatomaceous earth and was concentrated in vacuo yielding an oil. The oil was dissolved in ethyl acetate (700 mL) washed with brine-water (1:1, 1 L) and brine (0.5 L). The resulting aqueous phase was extracted with ethyl acetate (700 mL). This ethyl acetate phase was washed with brine-water (1:1, 1 L) and brine (0.5 L). The combined organic phases were dried over MgSO₄, filtered and concentrated in vacuo yielding the title compound as a yellow oil (116 g, 106 %). This material, which contained some entrained ethyl acetate, was of suitable purity to be used in subsequent steps without further purification.

**Step 4. Preparation of 6-chloro-7-(1,1-dimethylethyl)-2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylic acid.**

To a solution of the ester (Step 3) (116 g, 0.3 mole) in methanol (500 mL) and tetrahydrofuran
(500 mL) in a one liter flask was added aqueous sodium hydroxide (2.5 N, 240 mL, 0.6 mole). After stirring overnight, the pH of the solution was adjusted to 1 with concentrated hydrochloric acid and the solution was extracted with ethyl acetate. The ethyl acetate phase was dried over MgSO₄, filtered and concentrated in vacuo yielding a solid. This solid was dissolved in hot ethanol (500 mL). Water (500 mL) was added and upon cooling to room temperature crystals formed which were collected by vacuum filtration. The crystals were washed with ethanol-water (3:7, 3 X 200 mL) and dried providing the title acid as a crystalline solid (91.6 g, 91 %): mp 194.9-196.5 °C. ¹H NMR (acetone-d₆/300 MHz) 7.86 (s, 1H), 7.52 (s, 1H), 7.12 (s, 1H), 5.83 (q, 1H, J = 7.1 Hz), 1.48 (s, 9H). 6-Chloro-2-trifluoromethyl-2H-1-benzothiopyran-3-carboxylic acid

Step 1: Synthesis of 5-chloro-thiosalicylaldehyde.
Tetramethylethylenediamine (TMEDA) (10.44 mL, 8.035 g, 69.15 mmol) was added via syringe to n-BuLi (43.22 mL of 1.6 M in hexanes, 69.15 mmol) and the solution was chilled to 0 °C. A solution of 4-chlorothiophenol (5.00 g, 34.57 mmol) in cyclohexane (25 mL) was added with stirring over 1 hour. The resulting tan slurry was stirred overnight at room temperature, chilled to 0 °C, and DMF (2.94 mL, 2.78 g, 38.03 mmol) was added via syringe over 2 minutes. The resulting gummy slurry was stirred at room temperature for 30 hours and became a powdery suspension. A mixture of 2 N HCl and ice was added to the reaction mixture until the pH
became acidic (pH = 1). During this addition, the mixture warmed and became first red and then pale yellow. This mixture was extracted with ethyl acetate. The combined organic layers were washed with brine, dried over MgSO₄, filtered and concentrated in vacuo yielding a clear red-brown oil. This oil was triturated with hexanes yielding a red-brown semisolid. This semisolid was purified by plug flash chromatography over silica gel, eluting with 1:1, hexanes:dichloromethane to afford 5-chlorothiosalicylaldehyde (0.858 g, 14%) as an intensely yellow solid suitable for use without further purification.

**Step 2: Preparation of ethyl 6-chloro-2-trifluoromethylbenzo-1-thiopyran-2-H-3-carboxylate.**

5-Chloro-thiosalicylaldehyde (Step 1) (0.84 g, 4.86 mmol) was added to DMF (3 mL) and ethyl 4,4,4-trifluorocrotonate (1.10 mL, 1.22 mmol). With stirring, K₂CO₃ (0.67 g, 4.86 mmol) was added causing the reaction to become a deep red. After stirring overnight at room temperature, the reaction was diluted with diethyl ether and washed with water, saturated NaHCO₃ solution, aqueous KHSO₄ solution (0.25 M), brine, dried over MgSO₄, filtered and concentrated in vacuo yielding an oil. The oil was purified by flash chromatography (5:1; hexanes: ethyl acetate) yielding upon concentration ethyl 6-chloro-2-trifluoromethyl-benzo-1-thiopyran-2-H-3-carboxylate as a bright orange solid (0.492 g, 31%): mp 94.6-97.4 °C ¹H NMR (acetone d₆/300 MHz) δ 8.01 (s, 1H), 7.71 (d, 1H, J = 2.2 Hz), 7.50 (d, 1H, J = 8.5 Hz), 7.44 (d of d, 1H, J = 2.3, 8.3 Hz), 5.07 (q, 1H, J = 8.5 Hz), 4.42-4.23 (m, 2H), 1.35 (t, 3H, J = 7.1 Hz). FABLRMS m/z 329 (M+Li).

**Step 3: Preparation of 6-chloro-2-trifluoromethyl-benzo-1-thiopyran-2-H-3-carboxylic acid.**

To a stirred solution of the ester from Step 2 (0.413 g, 1.280 mmol) in THF: EtOH : H₂O (7 : 2 : 1, 10 mL) was
added NaOH solution (0.56 mL of 2.5 N solution, 1.408 mmol) with stirring. After stirring overnight, the reaction was partially concentrated in vacuo to remove the organic solvents, diluted with H₂O and washed with several portions of diethyl ether. Acidification of the stirred aqueous phase with concentrated HCl caused precipitation of a flocculent yellow precipitate. Vacuum filtration of the suspension yielded 6-chloro-2-trifluoromethyl-benzo-1-thiopyran-2H-3-carboxylic acid as a yellow powder (0.25 g, 66 %): mp 188.8-198.7 °C ¹H NMR (acetone d₆/300 MHz) δ 8.02 (s, 1H), 7.71 (d, 1H, J = 2.22 Hz), 7.50 (d, 1H, J = 8.5 Hz), 7.44 (d of d, 1H, J = 2.2, 8.5 Hz), 5.05 (q, 1H, J = 8.6 Hz). ¹⁹F NMR (Acetone d₆/282 MHz) δ -75.22 (d, J = 8.7 Hz). FABLRMS m/z 301 (M+Li); ESRMS (neg. ion) m/z 293 (M-H).

6-(Pentafluoroethyl)-2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylic acid

Step 1. Preparation of ethyl 6-(pentafluoroethyl)-2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylate.

Potassium pentafluoropropionate (0.476 g, 2.35 mmol) was dissolved in toluene (6 mL) and DMF (6 mL). The vessel was fitted with a distilling head, and CuI (0.471 g, 2.474 mmol) was added with stirring. The reaction was heated to
120 °C, removing the toluene by distillation. Ethyl 6-iodo-
2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylate (Example
72, Step 3) (0.469 g, 1.178 mmol) was added and the reaction
was heated to 150 °C for 2 hours. The reaction was allowed
to cool to room temperature and was partitioned between
diethyl ether and H₂O. The organic phase was dried over
MgSO₄, filtered and concentrated in vacuo. The resulting
residue was purified by flash chromatography (silica gel 60,
eluant: hexanes-ethyl acetate, 8:1) yielding, upon
concentration of the solution, the desired ester (0.096 g,
21%) as a tan solid mass of suitable purity to use without
further purification: ¹H NMR (acetone-d₆/300 MHz) 8.04 (s,

Step 2. Preparation of 6-(pentafluoroethyl)-2-
(trifluoromethyl)-2H-1-benzopyran-3-carboxylic acid.

To a stirred solution of the ethyl ester (Step 1) (0.090
g, 0.231 mmol) in THF:EtOH:H₂O (7:2:1) (4 mL) was added
aqueous NaOH solution (0.11 mL, 2.5 M). After stirring 16
hours, the reaction was partially concentrated in vacuo to
remove the organic solvents, diluted with H₂O, and washed
with diethyl ether. The resulting aqueous phase was
acidified with concentrated HCl, extracted with diethyl
ether, dried over MgSO₄, filtered and concentrated in vacuo
yielding an oil. The oil was purified by flash
chromatography (silica, hexanes-ethyl acetate, 3:1 with 5%
acetic acid). This procedure yielded the title acid (0.020
g, 24%) as a white powder: mp 162.3-164.7 °C. ¹H NMR

![Chemical Structure]
8-Chloro-6-(4-chlorophenoxy)-2-trifluoromethyl)-2H-1-
benzopyran-3-carboxylic acid

5 Step 1. Preparation of 5-phenoxy salicylaldehyde.

Ethyl magnesium bromide (67.5 mL of an approximately 3.0 M solution in diethyl ether, 202.5 mmol) was added to toluene (50 mL). A solution of 4-phenoxyphenol (25.00 g, 134.26 mmol) in diethyl ether (35 mL) was added resulting in the evolution of gas. The reaction was heated to 80 °C causing distillation of the diethyl ether. Toluene (300 mL), HMPA (23.4 mL, 24.059 g, 134.26 mmol), and paraformaldehyde (10.07 g, 335.65 mmol) were added and the reaction was heated to 85 °C for 4 hours. The reaction was cooled to room temperature and was acidified with 2N HCl. The resulting layers were separated and the organic phase collected. The organic phase was washed with brine. The combined aqueous phases were extracted with methylene chloride. The organic phases were combined, dried over MgSO₄, filtered and concentrated in vacuo yielding a yellow oil. The oil was purified by silica flash chromatography (hexanes-ethyl acetate, 95:5). Concentration in vacuo of the desired fractions provided the salicylaldehyde as a pale yellow powder (12.0 g, 42%) of suitable purity to use in subsequent steps.

Step 2. Preparation of 3-chloro-5-(4-
chlorophenoxy)salicylaldehyde.

To a stirred solution of the salicylaldehyde (Step 1) (0.981 g, 4.58 mmol) in acetic acid (20 mL) was added chlorine gas via a tube until the yellow color of chlorine persisted. After stirring for four hours at room temperature the reaction was sparged with nitrogen and diluted with water (50 mL). The resulting oily suspension was extracted with methylene chloride. The methylene chloride phase was washed with sodium bisulfite solution, dried over MgSO₄, filtered and concentrated in vacuo
providing the dichlorinated salicylaldehyde as a yellow oil (0.66 g, 51%) of suitable purity for use in subsequent steps without further purification.

Step 3. Preparation of ethyl 8-chloro-6-(4-chlorophenoxy)-2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylate.

A mixture of the dichlorinated salicylaldehyde (Step 2) (0.66 g, 2.3 mmol), triethylamine (0.49 g, 4.8 mmol), ethyl 4,4,4-trifluorocrotonate (0.59 g, 3.5 mmol) in dimethyl sulfoxide (5 mL) was heated to 85 °C for 3.5 hours. The reaction was allowed to cool to room temperature and was diluted with ethyl acetate (50 mL). The resulting mixture was washed with 3 N HCl (50 mL), aqueous potassium carbonate solution (10 weight %, 2 X 30 mL), and brine. The organic phase was dried over MgSO₄, filtered and concentrated in vacuo yielding a brown oil. This oil was purified by flash silica chromatography (hexanes-ethyl acetate, 9:1) providing the substituted 2H-1-benzopyran (0.39 g, 39%) of suitable purity to use in subsequent steps without further purification.

Step 4. Preparation of 8-chloro-6-(4-chlorophenoxy)-2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylic acid.

To a solution of the substituted 2H-1-benzopyran ethyl ester (Step 3) (0.37 g, 0.85 mmol) in ethanol-THF (4 mL, 1:1) was added sodium hydroxide solution (2 mL of 2.5 N, 5 mmol). After stirring for six hours the mixture was concentrated in vacuo. Acidification of the mixture with 3 N HCl yielded a solid which was collected by vacuum filtration. This solid was recrystallized from ethanol-water yielding the title compound as yellow crystals (0.134 g, 38%): mp 227.8-228.9 °C. ¹H NMR (acetone-d₆/300 MHz) 7.93 (s, 1H), 7.42 (d, 2H, J = 8.9 Hz), 7.24 (s, 2H), 7.12 (d, 2H, J = 8.9 Hz), 5.97 (q, 1H, J = 7.1 Hz). 6-Chloro-2-(trifluoromethyl)-4-ethenyl-2H-1-benzopyran-3-carboxylic acid

Step 1: Preparation of ethyl 3-(5-chloro-2-hydroxyphenyl)-3-oxo-propionate

A solution of lithium hexamethyldisilazide (800 mL of 1.0 M solution in THF, 800.0 mmol) was chilled to -78 °C under a nitrogen atmosphere. A solution of 5-chloro-2-hydroxyacetophenone (45.493 g, 266.67 mmol) in THF (130 mL)
was added dropwise to the stirred solution over 0.5 hour. The reaction was held at -78 °C for 1 hour, warmed to -10 °C for 2 hours, warmed to 0 °C for 1 hour, then cooled to -78 °C. Diethyl carbonate (35.54 mL, 34.65 g, 29.34 mmol) was added via syringe in one portion. The temperature was maintained at -78 °C for 0.5 hour, warmed to room temperature over 0.5 hour, and stirred for 3 hours. The crude reaction mixture was carefully poured over a mixture of rapidly stirred ice (1200 mL)/conc HCl (222 mL). The layers were separated and the aqueous phase was extracted with ethyl acetate. The combined organic phase was washed with brine, dried over Na$_2$SO$_4$, filtered and concentrated in vacuo yielding an oil that began to crystallize. Hexanes (150 mL) was added and crystallization proceeded. The crystalline product was collected by vacuum filtration to afford the title compound (29.04 g, 45%) as tan crystalline needles: mp 71.8-73.1 °C. $^1$H NMR (CDCl$_3$/300 MHz) 7.63 (d, 1H, $J = 2.4$ Hz), 7.45 (dd, 1H, $J = 8.9, 2.6$), 6.98 (d, 1H, $J = 8.9$ Hz), 4.25 (q, 2 H, $J = 7.3$ Hz), 3.98 (s, 2H), 1.29 (t, 3H, $J = 7.3$ Hz). **Step 2. Preparation of ethyl 2-(trifluoromethyl)-6-chloro-4-oxo-4H-1-benzo[3-carboxylate.**

The keto-ester (Step 1) (19.2 g, 79.1 mmol), was added to trifluoroacetic anhydride (67.2 mL, 49.9 g, 475.8 mmol), potassium carbonate (44 g, 318 mmol) and toluene (400 mL). This suspension was stirred at room temperature for 36 hours, then heated to reflux for 4 hours. After cooling to room temperature, the suspension was poured over rapidly stirred (mechanical stirrer) ice (300 mL) and aqueous HCl (12 N, 50 mL). The resulting organic phase was separated from the clear mixture, was washed with water (5 X 500 mL), brine (1 X 500 mL), dried over MgSO$_4$, filtered and concentrated in vacuo yielding tan solid which was dried under high vacuum. This sample was partially dissolved in

The filtrate was allowed to cool to room temperature yielding the desired 4-oxo-4H-1-benzopyran as a fluffy tan solid (14.17 g, 56%): mp 106.7-108.6 °C. This material was of suitable purity to use in the next step without further purification.

A stirred, chilled (0 °C) solution of the ketone (Step 2) (6.92 g, 21.58 mmol) in tetrahydrofuran (40 mL) and ethanol (50 mL) was treated portion-wise with sodium borohydride (NaBH₄, 0.41 g, 10.79 mmol). After 3 h additional sodium borohydride (0.30 g, 7.93 mmol) was added portion-wise over 1 hour. The reaction was poured into rapidly stirred cold aqueous HCl (15 mL of 12 N HCl diluted to 300 mL). During the addition a precipitate formed, that was collected by vacuum filtration and dried under high vacuum yielding the desired substituted 4-oxo-dihydro-1-benzopyran as a white powder (6.92 g, 99%): mp 80.2-84.9 °C. ¹H NMR (CDCl₃/300 MHz) 12.60 (br s, 1H), 7.69 (d, 1H, 2.6 Hz), 7.34 (dd, 1H, 2.6, 8.7 Hz), 6.93 (d, 1H, 8.7 Hz), 5.59 (q, 1H, 6.6 Hz), 4.46-4.23 (m, 2H), 3.35 (t, 3H, 7.0 Hz). 6-Chloro-7-methyl-2-(trifluoromethyl)-2H-1-benzothiopyran-3-carboxylic acid

Step 1. Preparation of N,N-dimethyl-O-(4-chloro-2-formyl-5-methylphenyl) thiocarbamate.

A mixture of 5-chloro-4-methylsalicylaldehyde (12.96 g, 76.0 mmol) and triethylamine (11.58 g, 114.4 mmol) was dissolved in anhydrous DMF (15 mL) treated with N,N-dimethylthiocarbamoyl chloride (11.25 g, 91.0 mmol) and stirred at room temperature for 16 hours. The reaction was treated with 3 N HCl (50 mL) and filtered to give an orange solid. The solid was dissolved in ethyl acetate washed with 3 N HCl, water, brine, dried over anhydrous MgSO4, filtered and concentrated in vacuo to afford a brown solid (16.79 g) which was recrystallized from diethyl ether/hexane to give the O-aryl thiocarbamate as a tan solid (4.92 g, 25%): 1H
NMR (acetone-\textit{d6}/300 MHz) 9.96 (s, 1H), 7.80 (s, 1H), 7.19 (s, 1H), 3.46 (s, 3H), 3.42 (s, 3H), 2.43 (s, 3H).

The \textit{O-}aryl thiocarbamate (Step 1) (4.92 g, 19.1 mmol) was dissolved in \textit{N,N}-dimethylaniline (25 mL) and immersed in and stirred at 200 °C for 1.5 hours. The reaction mixture was cooled to room temperature and poured into a mixture of 3 N HCl (200 mL) and ice. Filtration gave a brown semisolid which was dissolved in ethyl acetate, washed with 3 N HCl, brine, dried over anhydrous MgSO4, filtered and concentrated in vacuo to afford the \textit{S-}arylthiocarbamate as a brown oil (3.80 g, 77%) which was used in the next step without further purification.

Step 3. Preparation of \textit{ethyl 6-chloro-7-methyl-2-(trifluoromethyl)-2H-1-benzothiopyran-3-carboxylate}.

The \textit{S-}arylthiocarbamate (Step 2) (3.80 g, 14.7 mmol) was dissolved in THF (10 mL) and ethanol (10 mL), treated with 2.5 N sodium hydroxide (16.5 mL, 34.2 mmol), and stirred at room temperature for 0.9 hours. The reaction was diluted with diethyl ether and washed with 3 N HCl, brine, dried over MgSO4, filtered and concentrated in vacuo to yield the crude substituted 2-mercaptobenzaldehyde as a brown oil (2.82 g). This oil was added to DMF (10 mL) and ethyl 4,4,4-trifluorocrotonate (3.89 g, 23.1 mmol). With stirring, K$_2$CO$_3$ (3.23 g, 23.4 mmol) was added causing the reaction to become a deep red. The reaction was stirred at room temperature for 14.5 hours, acidified with 3 N HCl, extracted with ethyl acetate. The resulting organic phase was washed with brine, dried over MgSO4, filtered and concentrated in vacuo to give a yellow solid (6.36 g) which was used in the next step without further purification.
Step 4. Preparation of 6-chloro-7-methyl-2-
(trifluoromethyl)-2H-1-benzothiopyran-3-carboxylic acid

The ester from Step 3 (2.02 g, 6.0 mmol) was dissolved in THF (10 mL) and ethanol (10 mL), treated with 2.5 N sodium hydroxide (5.5 mL, 13.8 mmol), and stirred at room temperature for 4.8 hours. The reaction mixture was concentrated in vacuo, acidified with 3 N HCl yielding a suspension. The solid was collected by filtration and was recrystallized from ethanol-water to yield the title compound as a yellow solid (0.20 g, 11%): mp 240.5-241.7 °C. 

$^1$H NMR (acetone-d6/300 MHz) 7.99 (s, 1H), 7.67 (s, 1H), 7.43 (s, 1H), 4.99 (q, 1H, $J = 8.5$ Hz), 2.39 (s, 3H). FABHRMS m/z 307 (M-H). FABHRMS m/z 306.9831 (M-H, Calc’d 306.9807). Anal. Calc’d for C$_6$H$_4$CIF$_3$O$_2$: C, 46.69; H, 2.61; Cl, 11.48. Found: C, 46.78; H, 2.61; Cl, 11.41.

dihydro[1,8]napthyridine-3-carboxylic acid

**Step 1. Preparation of N-[5-chloropyridin-2-yl]-2,2-dimethylpropanamide.**

To 2-amino-5-chloropyridine (10.0 g, 0.078 mol) (Aldrich) and triethylamine (12 mL, 0.086 mol) in methylene chloride (200 mL), at 0 °C, was added dropwise to trimethylacetyl chloride (10.60 mL, 0.09 mmol) in methylene chloride (15 mL). The solid was collected by filtration affording the amide as a white solid (14.96 g, 90%): mp 51.4 - 53.4 °C. ¹H NMR (CDCl₃/300 MHz) 8.25-8.15 (m, 2H), 8.00 (br s, 1H), 7.68-7.60 (m, 1H), 1.28 (s, 9H). **Step 2. Preparation of N-[5-chloro-3-formylpyridin-2-yl]-2,2-dimethylpropanamide.**

To a chilled (-78 °C), stirred solution of the amide (Step 1) (5.0 g, 0.024 mole) in tetrahydrofuran (100 mL) was added t-butyl lithium (1.7M in pentane, 32.4 mL, 0.055 mole) dropwise. Dimethylformamide (2.3 mL, 0.03 mole) was added dropwise at -78 °C over 3 hours and the mixture allowed to warm room temperature. The reaction was quenched with ice water (200 mL) and extracted with ethyl acetate. The resulting organic phase was dried over MgSO₄, and was concentrated in vacuo to a volume of 20 mL. A white solid precipitated

EXAMPLE 175

\[(S)-6,8\text{-Dichloro-2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylic acid}\]

6,8-Dichloro-2-(trifluoromethyl)-2H-1-benzopyran-3-carboxylic acid (Example 32) (300 g, 1.04 mol) was added to ethyl acetate (750 mL). The mixture was stirred for 5 minutes, warmed to 70 °C and held at this temperature for 5 minutes. The resulting solution was cooled to 50 °C and (S)-(-)-α-methylbenzylamine (58 g, 0.48 mol) was added. Heptane (1880 mL) was added and the mixture stirred for 0.5 hour, then stirring was discontinued. The reaction was allowed to cool to 22 °C and stand for 8 hours. The salt crystallized during this time and was collected by vacuum filtration. The solid was washed with ethyl acetate-heptane (1:3, 2 X 50 mL). The solid obtained was dried at 40 °C under vacuum (20 mm) for 24 hours to give the salt (35 g, 16%).

A three-neck 2 L round bottom flask was purged with nitrogen and was charged with deionized water (750 mL) and the salt (103 g, 0.24 mole; This material was obtained using a similar procedure to that described above). To the resulting stirred suspension was added concentrated HCl (37 mL) drop-wise over 0.5 hours with good stirring below 20 °C causing the free carboxylic acid to precipitate. After stirring
for 2 hours, the suspension was vacuum filtered and the solid washed with deionized water (5 X 50 mL; until the washings were neutral). The solid was dried at 40 °C under vacuum (20 mm) for 12 hours yielding the title compound as a solid (74 g, 100%): mp 166.0-168.4 °C. 1H NMR (acetone-\textit{d}_6/300 MHz) 7.94 (s, 1H), 7.60 (s, 2H), 6.04 (q, 1H, \textit{J} = 6.8 Hz). ESIHRMS \textit{m/z} 310.9489 (M-H, Calc'd 310.9450). This compound was determined to have an optical purity of greater than 90% ee. The optical purity was determined by the method described in Example 66.

**BIOLOGICAL EVALUATION**

Rat Carrageenan Foot Pad Edema Test

The carrageenan foot edema test was performed with materials, reagents and procedures essentially as described by Winter, et al., (*Proc. Soc. Exp. Biol. Med.*, 111, 544 (1962)). Male Sprague-Dawley rats were selected in each group so that the average body weight was as close as possible. Rats were fasted with free access to water for over sixteen hours prior to the test. The rats were dosed orally (1 mL) with compounds suspended in vehicle containing 0.5% methylcellulose and 0.025% surfactant, or with vehicle alone. One hour later a subplantar injection of 0.1 mL of 1% solution of carrageenan/sterile 0.9% saline was administered and the volume of the injected foot was measured with a displacement plethysmometer connected to a pressure transducer with a digital indicator. Three hours after the injection of the carrageenan, the volume of the foot was again measured. The average foot swelling in a group of drug-treated animals was compared with that of a group of placebo-treated animals and the percentage inhibition of edema was determined (Otterness and Bliven, *Laboratory Models for Testing NSAIDs*, in Non-steroidal Anti-Inflammatory Drugs, (J. Lombardino, ed. 1985)). The %
inhibition shows the % decrease from control paw volume determined in this procedure and the data for selected compounds in this invention are summarized in Table I.

Evaluation of COX-1 and COX-2 activity in vitro

The compounds of this invention exhibited inhibition in vitro of COX-2. The COX-2 inhibition activity of the compounds of this invention illustrated in the Examples was determined by the following methods.

a. Preparation of recombinant COX baculoviruses

Recombinant COX-1 and COX-2 were prepared as described by Gierse et al, [J. Biochem., 305, 479-84 (1995)]. A 2.0 kb fragment containing the coding region of either human or murine COX-1 or human or murine COX-2 was cloned into a BamH1 site of the baculovirus transfer vector pVL1393 (Invitrogen) to generate the baculovirus transfer vectors for COX-1 and COX-2 in a manner similar to the method of D.R. O'Reilly et al (Baculovirus Expression Vectors: A Laboratory Manual (1992)). Recombinant baculoviruses were isolated by transfecting 4 μg of baculovirus transfer vector DNA into SF9 insect cells (2x10^8) along with 200 ng of linearized baculovirus plasmid DNA by the calcium phosphate method. See M.D. Summers and G.E. Smith, A Manual of Methods for Baculovirus Vectors and Insect Cell Culture Procedures, Texas Agric. Exp. Station Bull. 1555 (1987). Recombinant viruses were purified by three rounds of plaque purification and high titer (10^7-10^8 pfu/mL) stocks of virus were prepared. For large scale production, SF9 insect cells were
infecting in 10 liter fermentors (0.5 x 10^6/mL) with the recombinant baculovirus stock such that the multiplicity of infection was 0.1. After 72 hours the cells were centrifuged and the cell pellet homogenized in Tris/Sucrose (50 mM: 25%, pH 8.0) containing 1% 3-[3-cholamidopropyl]dimethylammonio]-1-propanesulfonate (CHAPS). The homogenate was centrifuged at 10,000xG for 30 minutes, and the resultant supernatant was stored at -80°C before being assayed for COX activity.

b. Assay for COX-1 and COX-2 activity

COX activity was assayed as PGE_2 formed/µg protein/time using an ELISA to detect the prostaglandin released. CHAPS-solubilized insect cell membranes containing the appropriate COX enzyme were incubated in a potassium phosphate buffer (50 mM, pH 8.0) containing epinephrine, phenol, and heme with the addition of arachidonic acid (10 µM). Compounds were pre-incubated with the enzyme for 10-20 minutes prior to the addition of arachidonic acid. Any reaction between the arachidonic acid and the enzyme was stopped after ten minutes at 37°C/room temperature by transferring 40 µl of reaction mix into 160 µl ELISA buffer and 25 µM indomethacin. The PGE_2 formed was measured by standard ELISA technology (Cayman Chemical). Results are shown in Table II.

c. Fast assay for COX-1 and COX-2 activity

COX activity was assayed as PGE_2 formed/µg protein/time using an ELISA to detect the prostaglandin released. CHAPS-solubilized insect cell membranes containing the appropriate COX enzyme were incubated in a potassium phosphate buffer (0.05 M Potassium phosphate, pH 7.5, 2 µM phenol, 1 µM heme, 300 µM epinephrine) with the addition of 20 µl of 100 µM arachidonic acid (10 µM). Compounds were pre-incubated with the enzyme for 10 minutes at 25°C prior to the addition of arachidonic acid. Any reaction between the arachidonic acid and the enzyme was
stopped after two minutes at 37 °C/room temperature by transferring 40 μl of reaction mix into 160 μl ELISA buffer and 25 μM indomethacin. The PGE₂ formed was measured by standard ELISA technology (Cayman Chemical). Results are shown in Table II.

Also embraced within this invention is a class of pharmaceutical compositions comprising the active compounds of Formula I in association with one or more non-toxic, pharmaceutically-acceptable carriers and/or diluents and/or adjuvants (collectively referred to herein as "carrier" materials) and, if desired, other active ingredients. The active compounds of the present invention may be administered by any suitable route, preferably in the form of a pharmaceutical composition adapted to such a route, and in a dose effective for the treatment intended. The active compounds and composition may, for example, be administered orally, intravascularly, intraperitoneally, subcutaneously, intramuscularly or topically.

The phrase "co-therapy" (or "combination-therapy"), in defining use of a cyclooxygenase-2 inhibitor agent and another pharmaceutical agent, is intended to embrace administration of each agent in a sequential manner in a regimen that will provide beneficial effects of the drug combination, and is intended as well to embrace co-administration of these agents in a substantially...
simultaneous manner, such as in a single capsule having a fixed ratio of these active agents or in multiple, separate capsules for each agent.

The phrase "therapeutically-effective" is intended to qualify the amount of each agent which will achieve the goal of improvement in disease severity and the frequency of incidence over treatment of each agent by itself, while avoiding adverse side effects typically associated with alternative therapies.

For oral administration, the pharmaceutical composition may be in the form of, for example, a tablet, capsule, suspension or liquid. The pharmaceutical composition is preferably made in the form of a dosage unit containing a particular amount of the active ingredient. Examples of such dosage units are tablets or capsules. The active ingredient may also be administered by injection as a composition wherein, for example, saline, dextrose or water may be used as a suitable carrier.

The amount of therapeutically active compounds which are administered and the dosage regimen for treating a disease condition with the compounds and/or compositions of this invention depends on a variety of factors, including the age, weight, sex and medical condition of the subject, the severity of the disease, the route and frequency of administration, and the particular compound employed, and thus may vary widely. The pharmaceutical compositions may contain active ingredients in the range of about 0.1 to 2000 mg, preferably in the range of about 0.5 to 500 mg and most preferably between about 1 and 100 mg. A daily dose of about 0.01 to 100 mg/kg body weight, preferably between about 0.5 and about 20 mg/kg body weight and most preferably between about 0.1 to 10 mg/kg body weight, may be appropriate. The daily dose can be administered in one to four doses per day.

In the case of psoriasis and other skin conditions, it may be preferable to apply a topical preparation of
compounds of this invention to the affected area two to four times a day.

For inflammations of the eye or other external tissues, e.g., mouth and skin, the formulations are preferably applied as a topical ointment or cream, or as a suppository, containing the active ingredients in a total amount of, for example, 0.075 to 30% w/w, preferably 0.2 to 20% w/w and most preferably 0.4 to 15% w/w. When formulated in an ointment, the active ingredients may be employed with either paraffinic or a water-miscible ointment base. Alternatively, the active ingredients may be formulated in a cream with an oil-in-water cream base. If desired, the aqueous phase of the cream base may include, for example at least 30% w/w of a polyhydric alcohol such as propylene glycol, butane-1,3-diol, mannitol, sorbitol, glycerol, polyethylene glycol and mixtures thereof. The topical formulation may desirably include a compound which enhances absorption or penetration of the active ingredient through the skin or other affected areas. Examples of such dermal penetration enhancers include dimethylsulfoxide and related analogs. The compounds of this invention can also be administered by a transdermal device. Preferably topical administration will be accomplished using a patch either of the reservoir and porous membrane type or of a solid matrix variety. In either case, the active agent is delivered continuously from the reservoir or microcapsules through a membrane into the active agent permeable adhesive, which is in contact with the skin or mucosa of the recipient. If the active agent is absorbed through the skin, a controlled and predetermined flow of the active agent is administered to the recipient. In the case of microcapsules, the encapsulating agent may also function as the membrane.

The oily phase of the emulsions of this invention may be constituted from known ingredients in a known manner. While the phase may comprise merely an emulsifier, it may comprise a mixture of at least one
emulsifier with a fat or an oil or with both a fat and an oil. Preferably, a hydrophilic emulsifier is included together with a lipophilic emulsifier which acts as a stabilizer. It is also preferred to include both an oil and a fat. Together, the emulsifier(s) with or without stabilizer(s) make-up the so-called emulsifying wax, and the wax together with the oil and fat make up the so-called emulsifying ointment base which forms the oily dispersed phase of the cream formulations. Emulsifiers and emulsion stabilizers suitable for use in the formulation of the present invention include Tween 60, Span 80, cetostearyl alcohol, myristyl alcohol, glyceryl monostearate, and sodium lauryl sulfate, among others.

The choice of suitable oils or fats for the formulation is based on achieving the desired cosmetic properties, since the solubility of the active compound in most oils likely to be used in pharmaceutical emulsion formulations is very low. Thus, the cream should preferably be a non-greasy, non-staining and washable product with suitable consistency to avoid leakage from tubes or other containers. Straight or branched chain, mono- or dibasic alkyl esters such as di-isoadipate, isocetyl stearate, propylene glycol diester of coconut fatty acids, isopropyl myristate, decyl oleate, isopropyl palmitate, butyl stearate, 2-ethylhexyl palmitate or a blend of branched chain esters may be used. These may be used alone or in combination depending on the properties required. Alternatively, high melting point lipids such as white soft paraffin and/or liquid paraffin or other mineral oils can be used.

Formulations suitable for topical administration to the eye also include eye drops wherein the active ingredients are dissolved or suspended in suitable carrier, especially an aqueous solvent for the active ingredients. The antiinflammatory active ingredients are preferably present in such formulations in a concentration of 0.5 to 20%, advantageously 0.5 to 10% and particularly about 1.5% w/w.
For therapeutic purposes, the active compounds of this combination invention are ordinarily combined with one or more adjuvants appropriate to the indicated route of administration. If administered per os, the compounds may be admixed with lactose, sucrose, starch powder, cellulose esters of alkanoic acids, cellulose alkyl esters, talc, stearic acid, magnesium stearate, magnesium oxide, sodium and calcium salts of phosphoric and sulfuric acids, gelatin, acacia gum, sodium alginate, polyvinylpyrrolidone, and/or polyvinyl alcohol, and then tableted or encapsulated for convenient administration. Such capsules or tablets may contain a controlled-release formulation as may be provided in a dispersion of active compound in hydroxypropylmethyl cellulose. Formulations for parenteral administration may be in the form of aqueous or non-aqueous isotonic sterile injection solutions or suspensions. These solutions and suspensions may be prepared from sterile powders or granules having one or more of the carriers or diluents mentioned for use in the formulations for oral administration. The compounds may be dissolved in water, polyethylene glycol, propylene glycol, ethanol, corn oil, cottonseed oil, peanut oil, sesame oil, benzyl alcohol, sodium chloride, and/or various buffers. Other adjuvants and modes of administration are well and widely known in the pharmaceutical art.
