NOTICE OF ENTITLEMENT

We  BRACKETT GREEN LIMITED

of  Severalls Lane, Colchester, ESSEX CO4 4PD ENGLAND

being the Applicant and Nominated Person in respect of the Australian National Phase of International Application No. PCT/GB91/00834, namely Application No. 79011/91, state the following:

Peter BLAKE is the actual inventor of the invention and made the invention for and on behalf of Sutcliffe Environmental Limited in the course of his duties as an employee of Sutcliffe Environmental Limited.

At the time the invention was made, Sutcliffe Environmental Limited was a wholly owned subsidiary of Sutcliffe Speakman PLC and Sutcliffe Speakman PLC was the applicant of the basic application listed in the declaration under Article 8 of the PCT, namely application no. 9011682.3 filed in the United Kingdom on 24 May 1990.

Sutcliffe Environmental Limited has changed its name to Brackett Green Limited and Sutcliffe Speakman PLC has assigned the right to claim convention priority from GB 9011682.3 to Brackett Green Limited.

GB 9011682.3 was the first application made in a Convention country in respect of the invention the subject of the International Application.

DATED this 1st day of December 1992

BRACKETT GREEN LIMITED
By its Patent Attorney

Claim:

1. A screening panel for use in a screening apparatus for removing solid material from a flowing liquid, the screening panel being moulded from a plastics material and being provided with a plurality of holes formed during the moulding process, the panel having a screening surface of an area greater than 500 cm², the holes each having a width of between about 1/2 and 10 mm, a depth at least as great as the width and being tapered from a relatively wide end on one face of the panel to a relatively narrow end on the other face.
An improved screening panel (1) for mounting on screening apparatus (6) to remove solid material from a flowing liquid, the panel (1) being moulded from a plastics material and being provided with a plurality of moulded holes (2) therein. The holes (2) may taper outwardly with distance from the screening side (3) of the panel to reduce clogging, in use, and initially, to facilitate the removal of the panel (1) from the mould.
The present invention relates generally to the field of water purification and treatment and is concerned particularly with a screening panel for removing solid material from a liquid in an early stage of a water purification system. Such screening panels are to be found, for example, in band screens and rotary screens in water and waste treatment plants, and are relatively large having an overall effective screening area that would usually be substantially more than 500 cm².

The design of a screening panel for such a system is at first sight straightforward. All that is required is a panel with a large number of suitably sized perforations. In a typical case, a panel would measure more than 20 cm x 30 cm and, even in the case where the perforations were relatively large, there would be more than 250 perforations on the panel. A complete screen would be made up of a number of (for example, from 4 to 80) panels.

Such screening panels have conventionally been made from perforated steel plate or from woven or welded wire mesh. Where steel plate is used, the perforations can be formed by punching or drilling out the steel plate. Where woven or welded wire mesh is used, square holes are often formed and a high percentage of open area can be provided, even with relatively small aperture sizes of for example a few mm.
With the advent of plastics materials, it has been proposed to manufacture screening panels from plastics material. In that case the panel is extruded as a sheet, cut to size and thereafter holes are drilled or punched in the panel to form the perforations. Drilling or punching the holes mimics the technique used when forming a panel from steel plate and does not pose any particular production problems.

British Patent Specification No. 1,521,255 describes a drum screen provided with plastics panels of 6 mm thickness and holes of 6 mm diameter formed by punching or drilling. The relatively thick panels define holes that are as deep as they are wide and that improves the performance of the panel as a screen.

At the present time, screening panels continue to be made in almost all cases of steel, either from steel mesh or by punching or drilling out steel plate.

A problem that arises with all screening panels of the kind referred to above is that debris tends to become trapped in the openings in the panels. Considerable efforts have been made in the past to overcome the problem, for example by providing some form of cleaning arrangement to clean the panels either by vigorous backwashing or mechanical brushing periodically; also it has been found that increasing the length of the holes in the panels reduces the tendency of the openings to become blocked as a result of doubling-over or "hairpinning" of the fibres.
It is an object of the present invention to provide an improved form of screening panel for use in a water treatment plant.

In a first aspect, the present invention provides a screening panel for use in a screening apparatus for removing solid material from a flowing liquid, the screening panel being moulded from a plastics material and being provided with a plurality of holes formed during the moulding process, the panel having a screening surface of an area greater than 500 cm², the holes each having a width of between about 1/2 and 10 mm, a depth at least as great as the width and being tapered from a relatively wide end on one face of the panel to a relatively narrow end on the other face.

In a second aspect, the present invention provides a band screen for removing solid material from waste water, the band screen including a plurality of screening panels, each panel being as defined according to the first aspect of the invention and being mounted to travel around an endless path which passes into and out of the water.

In a third aspect, the present invention provides a rotary screen of the drum, cup or disc type including a plurality of screen panels, each panel being as defined according to the first aspect of the invention and mounted to travel around an endless path which passes into and out of the water.

In a fourth aspect, the present invention provides a screening apparatus for removing solid material from a flowing liquid, the screening apparatus including a plurality of screening panels, each panel being mounted to travel around an endless path which passes into and out of the liquid, each screening panel being moulded from a plastics material and being provided with a plurality of holes formed during the moulding process, the holes extending from a first screening face of the panel which face, in use, confronts the flowing liquid, to a second offset face and being of circular cross-
section terminating at each face in a circular opening, the holes each having a depth at least as great as their diameter and reducing progressively in diameter from a relative wide end on the second face of the panel to a relatively narrow end on the first screening face of the panel.

Forming the holes in the screening panel by moulding (for example, by injection or pouring) has certain readily appreciated advantages:

a) because of the number of holes (more than 250) that will usually be found on a panel, and because a separate pin must be provided in the mould or forming tool for each hole to be formed, the forming of the mould is much more expensive than if the mould is designed to produce a plain (non-perforated) panel,

b) the many separate pins, which necessarily are close to one another, means that the mould designer has to worry about the flow of plastics material between the pins during the moulding process,

c) the many separate pins make it difficult to remove the formed panel after moulding, and

d) whereas moulding has significant cost advantages where mass production is involved, there is not usually
the opportunity to make screening panels having a particular arrangement of holes in great numbers because different screening apparatus will generally require different sizes of apertures.

We have found, however, that whilst the disadvantages referred to above do apply, they are outweighed by the surprising advantages that forming the holes in the moulding process provides. First and foremost of those is that the screening panel is much less likely to become blocked than when a conventional panel is used. We have found that where the holes are formed by drilling or punching, there is inevitably some roughness in the vicinity of the hole, whereas when the holes are moulded they have smoother openings as well as a significantly smoother finish on the interior walls, as compared with holes formed by drilling or punching.

In an especially advantageous and important embodiment of the invention the screening elements are provided with tapered holes. The screens are mounted with the narrower ends of the holes facing the flow so that liquid being screened enters the holes through the narrow ends. In the past it has been relatively difficult to provide tapered holes because such holes cannot be readily or cheaply produced either by punching or drilling. The present invention, however, provides a simple, quick and inexpensive method of producing such holes. The tapering of the holes actually facilitates the removal of the screening panel from the mould. The tapered configura-
tion of the holes provides a marked improvement in the performance of the screening panel. Whereas in the case of a straight hole, any fibres or particles entering that hole and having a width similar to the hole diameter would be likely to become lodged therein, with a tapered hole, such fibres or particles are much more likely to pass through any hole that they begin to enter since the hole increases in size downstream.

The invention may be employed to supply screening panels with aperture sizes ranging from 10 mm to as little as 1/2 mm but is especially applicable when holes of 5 mm or less, and in particular, 3 mm or less, are required. The use of a tapered hole confers advantages for all hole sizes, but becomes increasingly important as hole sizes decrease, in order to reduce clogging. When holes of 2 mm or less are required it is especially desirable for the holes to be tapered to prevent clogging.

Preferably, the holes are of circular cross-section so as to ensure uniformity of screening.

Preferably, the depth of each hole is greater than or equal to the greatest width of each hole on the screening side of the element. Such an arrangement, which can readily be provided when the holes are formed during moulding, is advantageous in preventing "hair-pinning".

The invention is especially useful where a screening element of increased thickness, is required, for example
having a thickness of 2mm or more, where the use of a metallic element is less desirable, and in particular, of 9mm or more, where the use of such an element becomes impracticable.

The screening panel is suitable for use in screening installations including a variety of screening apparatus. For example, it can be used in apparatus in which a plurality of such screening panels are brought in succession into a flowing liquid, such as, for example, on rotary screens of the drum, cup or disc type or on band screens. In the case of a band screen, it may be provided with moulded holes which, on the screening side, will usually have a minimum width of more than 2 mm (although minimum widths of 1mm may be possible with very fine sealing clearances). The screening panel may also be used on a screen known as a "brushed" or "fine brushed" screen, in which the panels are stationary.
The screening panel may be moulded from any plastics material that has suitable moulding characteristics, including a composite plastics material, such as, for example, a fibre-reinforced plastics material. One especially preferred material is polyurethane.

The invention also provides screening apparatus for removing solid material from a liquid flowing in a confined duct or channel, including a screening element that is moulded from plastics material and is provided with a plurality of holes formed during the moulding process.

A number of embodiments of the invention will now be described, by way of example only, with reference to the accompanying drawings, in which:

Fig. 1 is a schematic perspective view of a first screening panel for use on a drum screen;

Fig. 2a is a partial sectional view of the panel along line II-II of Fig. 1, to a larger scale than Fig. 1;

Fig. 2b is a schematic diagram showing the arrangement of the apertures;

Fig. 3 is a schematic perspective view of the drum screen;

Fig. 4 is a schematic perspective view of a second screening panel for use on a band screen; and,

Fig. 5 is a longitudinal sectional view of the band screen.
Referring to Fig. 1, the screening panel shown is suitable for use on a rotating drum screen of the type illustrated in Fig. 3.

The panel 1 is moulded with a plurality of apertures 2 from polyurethane. Each panel 1 is about 9 mm thick, has a length of about 1500 mm and a width of about 1000 mm.

The moulded apertures 2 occupy 30% of the total area of each panel 1 and are of circular cross-section. The apertures 2 have a diameter $D_1$ of about 2 mm on the screening side 3 of the panel and, as may be seen from Fig. 2a, flare outwardly with distance therefrom, to a diameter $D_2$ of about 2.5 mm on the opposite surface 4. The arrangement of the apertures 1 is as shown in Fig. 2b, where $d_1$ and $d_2$ are 3.4 mm and 5.8 mm respectively.

The screening panels 1 are mounted as a single row about the periphery 5 of the 5 m diameter drum screen 6, so that their longer edges 7 extend around its circumference. In certain instances, two or more such rows of panels may, however, be desirable. As indicated by arrows in Fig. 3, liquid enters the screen 6 through the two open sides thereof and flows outwardly through the screening panels 1 passing around the lowermost part of the screen. Thus, the screening side 3 of each panel faces radially inwards, with the holes tapering from 2.5 to 2 mm radially inwards.

The rims 8 of the screen 6 are finely sealed against
the passage of debris, thereby permitting finer screening. Whereas previously 2 mm apertures would have been provided by means of perforated steel plate or wire mesh elements, the present invention permits the use of plastics material enabling a smooth low friction surface to be provided over the surface of the screen and in the moulded apertures. Furthermore by virtue of the moulding process, there is no difficulty in having a panel thickness of 9 mm, leading to a substantial reduction in the extent to which the screen becomes clogged.

The tapered configuration of the holes further alleviates clogging, and in fact, without such tapering, the use of a 2 mm aperture size in conjunction with the 9 mm panel thickness, is unlikely to have been feasible. The tapered configuration is, of course, particularly suited for use with rotary screens where (in contrast, for example, to uniflow band screens) the liquid to be screened flows through the screening panels in only one direction.

A further advantage of the tapered hole construction is that it facilitates the removal of the panel from the mould.

Figure 4 shows an alternative type of screening panel for use on a uniflow band screen, as illustrated in Figure 5.

The panel 10 is moulded from polyurethane and comprises a rectangular screening face 11 provided with a plurality of apertures 12 therein, and two solid edge
faces 13 extending perpendicularly away from the longer edges 14 of the screening face 11, respectively. The panel 10 has a length of about 80 cm, a width of about 20 cm, and a thickness of about 5 mm, the edge faces 13 each having a width of about 4 cm.

The apertures 12 in the screening face 11 are formed during the moulding process. Each aperture 12 has a constant circular cross-section of 5 mm diameter, and of course, has a length of about 5 mm. The apertures 12 are arranged in rows about 7 mm apart, the centres of adjacent apertures in a row being separated by about 12 mm, adjacent apertures in alternate rows being offset by 6 mm. The apertures occupy about 50% of the effective screening area.

Referring to Fig. 5, each panel 10 is pivotally mounted lengthwise across the screen 15, with its edge faces 13 directed towards the interior of the screen so that the screening faces 11 of the panels face outwardly around the panel belt. In this band screen, cam means (not shown) are provided on the sides of the panels and travel along inner and outer guide tracks disposed around the path of the belt of panels so as to control the orientations of the panels 1.

During operation, on the upgoing side 16 of the panel belt, the leading edge faces 13 of the panels 10 are caused to move outwardly to form rising steps 17 that lift debris out of the flow. At the top of the screen, those edge faces 13 move inwardly again, causing the
debris to be knocked off the panels. The panels 10 are then caused to flatten to form a smooth surface 18, whereupon the panels are brushed and backwashed to remove finer screenings. The panels 10 then move downwardly and re-enter the flow 19 in the reverse orientation.

In this particular screen, stainless steel perforated plate panels having a 2 mm thickness and an aperture size of 6 mm were originally employed. When, in accordance with the invention, the panels were replaced by plastics panels provided with apertures of a similar size, the performance of the screen was found to be markedly improved over the original screen. In addition to the improvement in the frictional characteristics of the screening surfaces, the provision of the moulded apertures in the panels was found to result in fewer screenings being trapped in the apertures than was the case in the apertures of the perforated steel plate panels.

By virtue of the moulding process, it has also been possible to form the plastics panel of a thickness whereby the length of each aperture is at least as great as its diameter. This ratio significantly reduces the amount of "hairpinning" that occurs and also contributes to the improvement in performance.

In fact, the improved performance of the moulded plastics panel over the metal panel means that it may be possible to dispense entirely with backwashing spray jets (which contribute substantially to the running costs of
the screen), or at least to reduce backwashing to short periods.

The holes in the panels are of constant cross-section. However, if smaller aperture sizes are used, it may be desirable to make the holes tapered.
1. A screening panel for use in a screening apparatus for removing solid material from a flowing liquid, the screening panel being moulded from a plastics material and being provided with a plurality of holes formed during the moulding process, the panel having a screening surface of an area greater than 500 cm², the holes each having a width of between about 1/2 and 10 mm, a depth at least as great as the width and being tapered from a relatively wide end on one face of the panel to a relatively narrow end on the other face.

2. A panel as claimed in claim 1, wherein the widths of the holes on the screening side of the panel are less than or equal to 5 mm.

3. A panel as claimed in claim 2, wherein the widths of the holes on the screening side of the panel are less than or equal to 2 mm.

4. A panel as claimed in any of claims 1 to 3, wherein the holes are of circular cross-section.

5. A panel as claimed in any of claims 1 to 4, wherein the screening panel has a thickness of 2 mm or more.

6. A panel as claimed in any of claims 1 to 5, wherein the plastics material is polyurethane.

7. A screening panel for use in a screening apparatus for removing solid material from a flowing liquid, the panel being substantially as herein described with reference to and as illustrated by the accompanying drawings.
8. A band screen for removing solid material from waste water, the band screen including a plurality of screening panels, each being as defined in any of claims 1 to 7 and being mounted to travel around an endless path which passes into and out of the water.

9. A rotary screen of the drum, cup or disc type including a plurality of screening panels, each being as claimed in any of claims 1 to 7 and mounted to travel around an endless path which passes into and out of the water.

10. A screening apparatus for removing solid material from a flowing liquid, the screening apparatus including a plurality of screening panels, each panel being mounted to travel around an endless path which passes into and out of the liquid, each screening panel being moulded from a plastics material and being provided with a plurality of holes formed during the moulding process, the holes extending from a first screening face of the panel which face, in use, confronts the flowing liquid, to a second offset face and being of circular cross-section terminating at each face in a circular opening, the holes each having a depth at least as great as their diameter and reducing progressively in diameter from a relatively wide end on the second face of the panel to a relatively narrow end on the first screening face of the panel.
