Description of the Related Art

Corticotropin releasing factor (herein referred to as CRF), a 41 amino acid peptide, is the primary physiological regulator of proopiomelanocortin (POMC)-derived peptide secretion from the anterior pituitary gland (J. Rivier et al., Proc. Nat. Acad. Sci. (USA) 80:4851 (1983); W. Vale et al., Science 213:1394 (1981)). In addition to its endocrine role at the pituitary gland, immunohistochemical localization of CRF has demonstrated that the hormone has a broad extrahypothalamic distribution in the central nervous system and produces a wide spectrum of autonomic, electrophysiological and behavioral...
effects consistent with a neurotransmitter or neuromodulator role in brain (W. Vale et al., Rec. Prog. Horm. Res. 39:245 (1983); G.F. Koob, Persp. Behav. Med. 2:39 (1985); E.B. De Souza et al., J. Neurosci. 5:3189 (1985)). There is also evidence demonstrating that CRF may also play a significant role in integrating the response of the immune system to physiological, psychological, and immunological stressors (J.E. Blalock, Physiological Reviews 69:1 (1989); J.E. Morley, Life Sci. 41:527 (1987)).

Clinical data have demonstrated that CRF may have implications in psychiatric disorders and neurological diseases including depression, anxiety-related disorders and eating disorders. A role for CRF has also been postulated in the etiology and pathophysiology of Alzheimer's disease, Parkinson's disease, Huntington's disease, progressive supranuclear palsy and amyotrophic lateral sclerosis as they relate to the dysfunction of CRF neurons in the central nervous system (for review see E.B. De Souza, Hosp. Practice 23:59 (1988)).

In affective disorder, or major depression, the concentration of CRF is significantly increased in the cerebral spinal fluid (CSF) of drug-free individuals (C.B. Nemeroff et al., Science 226:1342 (1984); C.M. Banki et al., Am. J. Psychiatry 144:873 (1987); R.D. France et al., Biol. Psychiatry 28:86 (1988); M. Arato et al., Biol. Psychiatry 25:355 (1989)). Furthermore, the density of CRF receptors is significantly decreased in the frontal cortex of suicide victims, consistent with a hypersecretion of CRF (C.B. Nemeroff et al., Arch. Gen. Psychiatry 45:577 (1988)). In addition, there is a blunted adrenocorticotropic (ACTH) response to CRF (i.v. administered) observed in depressed patients (P.W. Gold et al., Am J. Psychiatry 141:619 (1984); F. Holsboer et al., Psychoneuroendocrinology 9:147 (1984); P.W. Gold et al., New Eng. J. Med. 314:1129 (1986)). Preclinical studies in rats and non-human primates provide additional support for the hypothesis that hypersecretion of CRF may be involved in the symptoms seen in human depression (R.M. Sapolsky, Arch. Gen. Psychiatry 46:1047 (1989)). There is preliminary evidence that tricyclic antidepressants can alter CRF levels and
thus modulate the number of CRF receptors in brain (Grigoriadis et al., *Neuropsychopharmacology* 2:53 (1989)).

There has also been a role postulated for CRF in the etiology of anxiety-related disorders. CRF produces anxiogenic effects in animals and interactions between benzodiazepine/non-benzodiazepine anxiolytics and CRF have been demonstrated in a variety of behavioral anxiety models (D.R. Britton *et al.*, *Life Sci.* 31:363 (1982); C.W. Berridge and A.J. Dunn *Regul. Peptides* 16:83 (1986)). Preliminary studies using the putative CRF receptor antagonist α-helical ovine CRF (9-41) in a variety of behavioral paradigms demonstrate that the antagonist produces "anxiolytic-like" effects that are qualitatively similar to the benzodiazepines (C.W. Berridge and A.J. Dunn *Horm. Behav.* 21:393 (1987), *Brain Research Reviews* 15:71 (1990)). Neurochemical, endocrine and receptor binding studies have all demonstrated interactions between CRF and benzodiazepine anxiolytics providing further evidence for the involvement of CRF in these disorders. Chlordiazepoxide attenuates the "anxiogenic" effects of CRF in both the conflict test (K.T. Britton *et al.*, *Psychopharmacology* 86:170 (1985); K.T. Britton *et al.*, *Psychopharmacology* 94:306 (1988)) and in the acoustic startle test (N.R. Swerdlow *et al.*, *Psychopharmacology* 88:147 (1986)) in rats. The benzodiazepine receptor antagonist (Ro15-1788), which was without behavioral activity alone in the operant conflict test, reversed the effects of CRF in a dose-dependent manner while the benzodiazepine inverse agonist (FG7142) enhanced the actions of CRF (K.T. Britton *et al.*, *Psychopharmacology* 94:306 (1988)).

The mechanisms and sites of action through which the standard anxiolytics and antidepressants produce their therapeutic effects remain to be elucidated. It has been hypothesized, however, that they are involved in the suppression of the CRF hypersecretion that is observed in these disorders. Of particular interest is that preliminary studies examining the effects of a CRF receptor antagonist (α-helical CRF₉₋₄₁) in a variety of behavioral paradigms have demonstrated that the CRF antagonist produces "anxiolytic-like" effects
qualitatively similar to the benzodiazepines (for review, see G.F. Koob and K.T. Britton, In: *Corticotropin-Releasing Factor: Basic and Clinical Studies of a Neuropeptide*, E.B. De Souza and C.B. Nemeroff eds., CRC Press p.221 (1990)).

In order to study these specific cell-surface receptor proteins, compounds must be identified that can interact with the CRF receptor in a specific manner dictated by the pharmacological profile of the characterized receptor. Toward that end, there is evidence that the direct CRF antagonist compounds and compositions of this invention, which can attenuate the physiological responses to stress-related disorders, will have potential therapeutic utility for the treatment of depression and anxiety-related disorders. acid, respectively. This derivative was reacted with the appropriate 2,4-substituted aniline (IV) in a high boiling solvent, such as, but not limited to, ethylene glycol, methoxyethoxyethanol etc., or in an aprotic solvent such as tetrahydrofuran, dioxane, toluene, xylene, or N,N-dimethylformamide, facilitated by the optional use of a base such as sodium hydride (NaH), lithium diisopropylamide (LDA), which are preferred. The coupled product (V) was treated with a base such as NaH or LDA in an aprotic solvent such as tetrahydrofuran (THF) or N,N-dimethylformamide (DMF) or in a combination of potassium tert-butoxide in t-butanol (tBuOK/tBuOH) followed by an alkylating agent R^4L', such as an alkyl iodide, mesylate or tosylate to afford the corresponding alkylated product of Formula (I).
The compounds of Formula (I), wherein V and Y are N and Z, J, K, and L are all CH, can be prepared as shown in Scheme 2. The substituted aniline (VI) was converted to the corresponding guanidinium salt (VII) by treatment with the appropriate reagent such as cyanamide.

\[
\text{(VI)} \quad \xrightarrow{\text{HNCN}} \quad \text{(VII)} \quad \xrightarrow{\text{R, L', base, $\Delta$}} \quad \text{(IX)} \quad \xrightarrow{\text{R, L', base, $\Delta$}} \quad \text{(X)}
\]

The guanidinium salt (VII) was reacted with a $\beta$-diketone (VIII) in the presence of a base such as potassium carbonate ($K_2CO_3$) in N,N-dimethylformamide (DMF) or in an alcoholic solvent in the presence of the corresponding alkoxide to afford the corresponding pyrimidine (IX). This was subsequently alkylated to provide (X), a compound of Formula (I) wherein $X'$ is hydrogen, by conditions identical to those described in Scheme 1.
Compounds of the Formula (I), wherein V and Y are N and Z, J, K, and L are all CH and R³ is NR⁶R⁷, can be prepared as shown in Scheme 3. Treatment of 2,4-dichloro-6-alkylpyrimidine (XI) with a primary or secondary amine in the presence of a non-nucleophilic base such as a trialkylamine afforded selectively the corresponding 4-substituted amino adduct (XII).

This in turn, was reacted with the substituted aniline (IV) under conditions identical to those described in Scheme 1 to afford the corresponding secondary pyrimidinamine (XIII). This was alkylated under conditions described in Schemes 1 and 2.
Compounds of Formula (I) wherein J, K, and L are CH and Z is CR² and V and Y are N can also be prepared by the route outlined in Scheme 4. The guanidinium salt (XII) was reacted with a β-ketoester (XV) in the presence of a base such as an alkoxide in the corresponding alcoholic solvent to give the adduct (XVI). Treatment of the hydroxy group in (XVI) with either phosphorous oxychloride, phosphorous oxybromide, methanesulfonyl chloride, p-toluenesulfonyl chloride, or trifluoromethanesulfonic anhydride provided (XVII), wherein the L is a leaving group and is, respectively, Cl, Br, I, OMs, OTs, or OTf. \]

Compounds of the Formula wherein X is other than bromine can be prepared by the intermediates shown in Scheme 5. Reaction of the 2-halo compound (V) wherein X is bromine or hydrogen with a metalating agent such as, but not limited to, n-BuLi or t-BuLi in an aprotic solvent, preferably ether or tetrahydrofuran, provided the corresponding 2-lithio intermediate (X = Li, not isolated) which was further reacted with an electrophile such as iodine or trimethyltin chloride ((CH$_3$)$_3$SnCl) to give the corresponding 2-substituted product (XIX). These intermediates can also be further reacted using palladium-catalyzed coupling reactions well known to one of skill in the art to prepare the compounds of the invention.

Compounds of the Formula (I) wherein Z, K and L are all CH, J is N or CH, and R$_4$ is ethyl can be prepared as illustrated in Scheme 6. Sequential addition/re-oxidation of an alkyl lithium to 2-chloropyrimidine can provide intermediate (XXII) wherein the R$^1$ and R$^2$ can be independent of one another. Displacement of the chlorine by a suitable nitrogen nucleophile such as an
aniline under similar conditions of Scheme 1, followed by attachment of the R¹ group by alkylation in an analogous method of Scheme 1 or 2 can provide the compounds of the invention.

Treatment of the appropriately ortho-functionalized aniline XXXIX with a substituted 2-mercaptopyrimidine XL in the presence of a base such as potassium carbonate, sodium carbonate, alkali metal alkoxide, potassium, sodium or lithium hydride, a lithium, sodium or potassium dialkylamide, or an alkali metal in the presence of copper powder or copper salts gives the corresponding aryl sulfide XLI which is subjected to a Smiles rearrangement by treatment with an strong acid such as hydrochloric, hydrobromic, hydriodic, sulfuric, phosphoric or perchloric, to give the corresponding disulfide XLIII. This is reduced to the sulfide XLIV with a reducing agent such as sodium borohydride and alkylated on the sulfur with the appropriate alkylating agent such as an alkyl halide, tosylate or mesylate. The rearrangement of XLI may be carried out with a strong base such as lithium, sodium, or potassium hydride; lithium, sodium, or potassium dialkylamide; or lithium, sodium or potassium metal, in an appropriate solvent such as decahydronaphthalene, xylenes, high boiling alcohols, dimethylformamide, dimethylsulfoxide, dimethylacetamide, and N-methylpyrrolidinone. The rearrangement product can be selectively alkylated on the sulfur with the use of a base such as potassium, sodium or lithium carbonate, potassium, sodium or lithium alkoxide, or trialkylamine and the appropriate alkylating agent as described above. The alkylsulfide can be further alkylated on the nitrogen by using identical conditions as described above to yield compound XLV.

Compounds of formula (I), wherein R² is (CH₂)₆OR₈ and R³ is (CH₂)₆C(=O)OR²⁴, (CH₂)₆C(=O)NR⁶R⁷, or (CH₂)₆NR⁶R⁷ can be made according to Scheme 12.
Compounds XLVII, XLVIII, and XLIX are made using the product of Example 24 as starting material by procedures analogous to those used to make the products of Examples 25, 16, and 17 respectively.

The novel 7-azaindoles of the present invention are prepared by Scheme 13 outlined below. The potassium salt of formylsuccinonitrile is treated with the appropriate substituted aniline L to give L1. This undergoes base catalyzed cyclization to a 1-aryl-2-amino-4-cyanopyrrole LII. Reaction with an appropriate 1,3-dicarbonyl compound gives the desired 7-azaindole LIII.
The nitrile substituent at position 3 of structure LIII is readily removed by refluxing the 3-cyano compound with 65% sulfuric acid. Position 3 then can be resubstituted by halogenation or nitration. Reduction of the nitro group can provide the 3-amino substituent.

Alternatively, the nitrile group can be converted to desired L groups by methods described in "Comprehensive Organic Transformations", by Richard C. Larock, VCH Publishers, Inc., New York, New York, 1989. For instance, the nitrile group can be reduced with diisobutylaluminum hydride to give the 3-aldehyde. The 3-aldehyde can be reduced via the hydrazone under Wolff-Kishner conditions (KOH in hot diethylene glycol) to give L = methyl. Furthermore, the aldehyde can be converted to L = CH=CH₂ by adding it to a mixture of methyltriphenylphosphonium bromide and potassium tertiary-butoxide in tetrahydrofuran (Wittig reaction). Reduction of the ethenyl
group to give L = CH₂CH₃ can be effected by hydroboration-protonolysis (J. Am. Chem. Soc. 81:4108(1959)).

Scheme 13 generally provides a mixture isomeric in substituents R¹ and R', which then can be separated. Sometimes the preferred isomer is the one obtained in lower yield. In that event Scheme 14 can be used to prepare the preferred isomer. Intermediate LII is treated with the appropriate acyl- or aroyl-acetic ester under either thermal or acid-catalyzed conditions to give the 6-hydroxy compound LV. Compound LV is converted to the 6-chloro compound LVI and de-cyanylated to compound LVII. When R¹ substituents other than chloro are desired, the chloro group can be converted to other substituents. For instance, treatment of compound LVII with an alkyl Grignard reagent can provide compound LVIII where R¹ = alkyl. Heating with a primary or secondary amine can provide compound LVIII where R¹ = amino.
Scheme 14

Scheme 15 affords another route to compounds of this invention. Intermediate LII can be treated with the appropriate acylacetaldehyde dialkyl acetal under acid catalyzed conditions to give compounds LXa and LXb, 7-azaindoles unsubstituted at positions 4 and 6 respectively. Compound LXa can be oxidized with m-chloroperoxybenzoic acid to give the N-oxide compound LXI. Heating compound LXI with phosphorus oxychloride can give compound XIIa, which can be decyanylated to compound LXIII.
Compound LXIV where \( R'^3 \) is an amino substituent can be prepared by heating LXIII with the appropriate amine; where \( R'^3 = \text{alkoxide} \), the metal alkoxide can be heated with LXIII; where \( R'^2 = \text{aryl} \), compound LXIII can treated with the arylboronic acid in the presence of tetrakis(triphenylphosphine)palladium (TTPP) and sodium carbonate; and where \( R'^3 = \text{alkyl, alkenyl, aralkyl, and cycloalkyl} \), compound LXIII can be coupled with the appropriate organotin reagent, also in the presence of TTPP.

Compound LXIV where \( R'^3 \) is a nitro group can be prepared by nitration of LXI, decyanylation, and reduction of the N-oxide with a trivalent phosphorus compound such as triethyl phosphite.

Compound LXb can be substituted in the 6 position using methods described for the substitution of LXa.
The novel 7-azabenzimidazoles of this invention can be prepared as outlined in Scheme 16 where R²⁹ is nitrogen. Compounds L and LXV can react upon heating in the presence of a base, e.g. sodium hydride, to give the diarylamine LXVI. Reduction of the nitro group with stannous chloride can give LXVII, which can be closed to the 7-azabenzimidazole LXVIII.
Scheme 16

The purines of this invention can be prepared as shown in Schemes 17 and 18.

Compounds L and LXIX (J. Heterocyclic Chem. 28:465 (1991)) can be heated in the presence of a base, e.g. sodium hydride, to give compound LXX. Heating LXX with the appropriate carboxylic acid in the presence of a mineral acid catalyst can give LXXI where $R^2$ is hydrogen, alkyl, alkenyl, or alkynyl. The chloro substituent can then be converted to $R^3$ to give compounds LXXII by using one of the methods described above for the introduction of $R^3$ to obtain compounds LXIV.
Scheme 18 can be used to prepare purines where $R_{25}^5$ is halogen or alkoxide. Compounds LXX can be heated with a dialkyl carbonate, such as diethyl carbonate, to give the carbonyl compound LXXIII; if the conversion is undesirably slow, more reactive species such as trichloromethyl chlorocarbonate or carbonyl diimidazole can be used in place of diethyl carbonate. The chloro substituent can then be converted to $R_3^5$ to give LXXIV by using one of the methods described above for the introduction of $R_3^3$ to obtain LXIV. Heating LXXIV with phosphorus oxychloride can give the 2-chloropurine, LXXV. To prepare the 2-alkoxypurines, LXXVI, LXXV can
be heated with a metal salt of the alcohol $R'^3OH$, e.g. the sodium or potassium salt, wherein in $R'^3$ is $C_1$-$C_4$ alkyl.

The method of synthesis of the 7-azaindolines of this invention is shown in Scheme 19.

A number of compounds of the general structure LXXVIII with desired $R^1$ and $R^2$ groups have been described by W. Paudler and T.-K. Chen, *J. Heterocyclic Chem.* 7:767 (1970). These can be oxidized with a peracid, e.g. m-chloroperoxybenzoic acid, to the sulfone LXXIX. Sulfone LXXIX can be heated in the presence of the desired aniline and a base, e.g. sodium hydride to give the diaryl amine LXXX. Alkylation of LXXX with the desired unsubstituted or 4-substituted 3-butynyl iodide (or 3-butynol mesylate) can give
LXXXI. LXXXI can undergo an intramolecular Diels-Alder reaction to give LXXXII.

In a number of cases, the desired 4-substituted 3-butynyl iodide is not readily available or is unstable. In that event unsubstituted 3-butynyl iodide is used to give compound LXXXII where $R^3 = H$.

Scheme 19
The synthesis of the 5,7-diazaindoles of this invention is outlined in Scheme 20.

The desired formamidine LXXXIII can be treated with LXXXIV in the presence of sodium ethoxide in ethanol to give the pyrimidine LXXXV. Refluxing LXXXV in phosphorus oxychloride gives the dichloropyrimidine LXXXVI. Compound LXXXVI can be converted to the carbonyl compound LXXXVII by treatment with one equivalent of ozone at -78°C to give an ozonide, which on treatment with sodium iodide and acetic acid gives the desired carbonyl compound. The preparation of LXXXVII (R¹ = H, R²⁸ = CH₃, and R¹ = R²⁵ = CH₃) by a different route has been described by E. Basagni, et al., Bull. Soc. Chim. Fr., 4338 (1969).

Before the coupling reaction, the carbonyl of compound LXXXVII is protected by treatment with 2,2-dimethoxypropane in the presence of a catalytic amount of acid to give compound LXXXVIII. Compound LXXXVIII is then coupled with the appropriate aniline L by heating in the presence of a base, e.g. sodium hydride, to give compound LXXXIX. Compound LXXXIX can be cyclized to give the 5,7-diazaindole XC, the target compound wherein R¹ = Cl. Compound XC is also a useful intermediate for the preparation of Compounds XCI with other R¹ groups. For example, heating the chloro compound with the appropriate amine gives the desired amino compound. Heating with a metal alkoxide gives the desired alkoxy compound. Treating compound XC (R¹ = Cl) with R³MgBr (R³ = alkyl, aryl, or aralkyl) converts the chloro compound to the desired alkyl, aryl, or aralkyl compound XCI.

This material is coupled to cyanuric chloride, then the secondary amine is alkylated in an analogous manner to that in Scheme 1 to yield XCIII. In this last instance, \( \text{R}^{25} = \text{R}^{25}\text{a} \). Ketones of Formula (XCVIII) can be converted to alcohols of Formula (C) by treatment with a reducing agent in an inert solvent. Such reducing agents include, but are not limited to, alkali metal aluminum hydrides, preferably lithium aluminum hydride, alkali metal borohydrides (preferably sodium borohydride), alkali metal trialkoxyaluminum hydrides (such as lithium tri-t-butoxyaluminum hydride), dialkylaluminum hydrides (such as di-isobutylaluminum hydride), borane, dialkylboranes (such as di-isoamyl borane), alkali metal trialkylboron hydrides (such as lithium triethylboron hydride). Inert solvents include lower alkyl alcohols of 1 to 6 carbons, ethereal solvents (such as diethyl ether or tetrahydrofuran), aromatic or non-aromatic hydrocarbons of 6 to 10 carbons. Reaction temperatures for the reduction range from about -78°C to about 200°C, preferably about 0°C to about 120°C. The choice of reducing agent and solvent is known to those skilled in the art as taught in the above cited March reference (Advanced Organic Chemistry, pp. 1093-1110).

Compounds of Formula (I) can also be prepared by the procedures outlined in Scheme 23. A compound of Formula (CI) (Formula I, where Z = CR², Y = N, R³ = (CHR⁶)pCN) can be reacted with sodium azide and ammonium chloride in a polar solvent at high temperatures (preferably 70 to 150°C) to give a tetrazole of Formula (CII) as taught by the prior art (cf. R.N. Butler, Tetrazoles, in Comprehensive Heterocyclic Chemistry; A.R. Katritzky, C.W. Rees, Eds.; (New York: Pergamon Press, 1984), pp. 828-832). Such polar solvents may be dialkylformamides (preferably N,N-dimethylformamide), dialkylacetamides, (preferably N,N-dimethylacetamide), cyclic amides, (preferably N-methylpyrrolidinone), dialkyl sulfoxides (preferably dimethyl sulfoxide) or dioxane. A compound of Formula (CIII) (Formula I, where Y = N, Z = CR² and R³ = COCH₃) may be treated with a halogenating agent in an inert solvent to give a haloketone of Formula (CIV). Such halogenating agents include bromine, chlorine, iodine, N-halosuccinimides (e.g. N-bromosuccinimide), N-halophthalimides (e.g., N-bromophthalimide) or N-tetrasubstituted ammonium perbromides (e.g., tetraethylammonium perbromide) (cf. the above March reference, Advanced Organic Chemistry, pp. 539-533; S. Kajigaeshi, T. Kakinami, T. Okamoto, S. Fujisaki, Bull. Chem. Soc. Japan 60:1159-1160 (1987) and references cited therein). Inert solvents include lower halocarbons of 1 to 6 carbons and 2 to 6 halogens (preferably dichloromethane or dichloroethane), dialkyl ethers of 4 to 10 carbons, cyclic ethers of 4 to 10 carbons (preferably dioxane) or aromatic hydrocarbons to 6 to 10 carbons. Haloketones of Formula (CIV) may be converted to imidazoles of Formula (CVII) by treatment with formamide with or without an inert solvent as taught by the prior art (H. Brederick and G. Theilig, Chem. Ber. 86:88-108 (1953)). Alternatively, ketones of Formula (CIII) may be converted to vinylogous amides (CV) by reaction with N,N-di(lower alkyl)formamide di(lower alkyl)acetals (e.g., N,N-dimethylformamide dimethyl acetal) or Gold's reagent ((dimethylaminomethyleneaminomethylenedimethylammonium chloride) in an inert solvent with or without base as taught by the prior art (cf. J.T.

The purines and 8-aza-purines of the present invention are readily synthesized following the methods shown in Schemes 24 and 25. The purine (CXI) is derived from an appropriately substituted pyrimidine (CVIII). The trisubstituted hydroxypyrimidine is nitrated under standard conditions with fuming nitric acid. Following conversion of the hydroxy compound to the chloro derivative via treatment with phosphorus oxychloride, reduction of the nitro group with iron powder in acetic acid and methanol yielded the aminopyrimidine (CIX). Compound CIX is reacted with the appropriately substituted aniline in the presence of base catalyst to yield an anilinopyrimidine (CX), which was then converted to the desired purine (CXI) via reaction with triethylorthoformate in acetic anhydride. Starting from compound CX, the desired 8-aza-purine can be prepared via reaction with sodium nitrite in acetic acid.

If R^3 of the purine is a chloro group, that substituent can be further elaborated to other R^3 substituents as shown in Scheme 25. Compound (CXII), wherein R^3 is chlorine, is reacted with a nucleophile with or without an inert solvent at temperatures ranging from 20°C to 200°C, to effect the formation of the 8-azapurine (CXIII). In a similar fashion, the R^3 of an appropriately substituted purine (CXI) may be converted to other functional groups to yield the purine (CXIV) having the desired substitution pattern. Similarly, if R^1 is a chloro group, it may be converted to another functional group via reaction with an appropriate nucleophile. Nucleophiles include amine, hydroxy, or mercapto compounds or their salts.

**Scheme 25**
Compounds of the Formula (I) wherein J, K, and/or L are N, such as (CXXVII), (CXXVIII), (CXXIX), or (CXXX), were prepared according to Schemes 26 and 27. The preparation of the lower ring heterocycle of the compound of the Formula (I) is shown in Scheme 26.

2,4-Dihydroxy-5-nitropyrimidine (CXV) was first converted to the dichloro compound (CXVI) via treatment with phosphorus oxychloride. Compound (CXVI) was then converted to the symmetrically bis-substituted pyrimidines, (CXVII) and (CXVIII), via reaction with the appropriate R$^5$ or X group radicals, MR$^5$ and MX, respectively, where M is a metal atom. It is understood that compounds of the Formula (I) wherein R$^5$ and X have the same definition fall within the scope of this invention. A method of forming the unsymmetrically bis-substituted compounds (CXIX) and (CXX) is treatment of (CXVI) with equimolar amounts of MR$^5$ and X to form a statistical distribution of products, (CXVII), (CXVIII), (CXIX) and (CXX), which can be purified by standard techniques, such as, recrystallization or chromatography.

The desired (N-pyrimidino-N-alkyl)aminopyrimidines of the present invention were prepared according to Scheme 27. An appropriately substituted 2-hydroxypyrimidine (CXXI) was converted to the 2-chloropyrimidine (CXXII) via treatment with phosphorus oxychloride. The intermediate (N-pyrimidino)aminopyrimidines, (CXXIII), (CXXIV), (CXXV), and (CXXVI), were prepared via treatment of (CXXII) with the appropriate 5-aminopyrimidine, (CXVII), (CXVIII), (CXIX) and (CXX) respectively, in the presence of a base, such as, NaH. Simple alkylation of the amino groups in (CXXIII), (CXXIV), (CXXV), and (CXXVI) via treatment with R$^4$I and sodium hydride gave the desired (N-pyrimidino-N-alkyl)aminopyrimidines, (CXXVII), (CXXVIII), (CXXIX), and (CXXX).

The (N-heterocycle-N-alkyl)aminopyridines or N-heterocycle-N-alkyl)aminotriazines of the present invention may also be prepared according to Scheme 28. Commercially available amino substituted heterocycles (CXXXI) may be brominated using a tetrastubstituted ammonium tribromide, preferably benzyltrimethylammonium tribromide (BTMA Br₃) to yield the appropriately substituted o-bromo-aminoheterocycle (CXXXII). Such reactions are carried out in an inert solvent, such as, lower alcohols or halocarbons of 1 to 4 carbons and 1 to 4 halogens in the presence of a base, such as, alkali metal or alkaline earth metal carbonates. Compound (CXXXII) is then coupled to a substituted pyrimidine or triazine (CXXXIII) to form an (N-heterocycle)aminopyrididine (CXXXIVa) or (N-heterocycle)aminotriazine (CXXXIVb). (CXXXIVa or b) is then further alkylated in the presence of a base to the target (N-heterocycle-N-alkyl)aminopyrididine (CXXXVa) or (N-heterocycle-N-alkyl)aminotriazine (CXXXVb), respectively.

**Utility**

**In vitro Receptor Binding Assay:**

**Tissue Preparation:** Male Sprague Dawley rats (180-200 g) were sacrificed by decapitation and the cortex was dissected on ice, frozen whole in liquid nitrogen and stored at -70°C until use. On the day of assay, frozen tissue was weighed and homogenized in 20 volumes of ice cold buffer containing 50 mM Tris, 10 mM MgCl<sub>2</sub>, 2 mM EGTA, pH 7.0 at 22°C using a Polytron (Brinkmann Instruments, Westbury, NY; setting 6) for 20 s. The homogenate was centrifuged at 48,000 x g for 10 min at 4°C. The
supernatant was discarded, and the pellet was re-homogenized in the same volume of buffer and centrifuged at 48,000 x g for 10 min at 4°C. The resulting pellet was resuspended in the above buffer to a final concentration of 20-40 mg original wet weight/mL and used in the assays described below. Protein determinations were performed according to the method of Lowry (Lowry et al., J. Biol. Chem. 193:265 (1951)) using bovine serum albumin as a standard.

**CRF Receptor Binding:** Receptor binding assays were carried out essentially as described by E.B. De Souza, J. Neurosci. 7:88 (1987).

**Saturation Curve Analysis**

In saturation studies, 100 µl [125I]-ovine CRF (50 pM - 10 nM final concentration), 100 µl of assay buffer (with or without 1 mM r/hCRF final concentration, to define the non-specific binding) and 100 µl of membrane suspension (as described above) were added in sequence to 1.5 mL polypropylene microfuge tubes for a final volume of 300 µl. All assays were carried out at equilibrium for 2 h at 22°C as described by E.B. De Souza, J. Neurosci. 7:88 (1987). The reaction was terminated by centrifugation of the tubes in a Beckman microfuge for 5 min at 12,000 x g. Aliquots of the supernatant were collected to determine the "free" radioligand concentration. The remaining supernatant was aspirated and the pellets washed gently with ice-cold PBS plus 0.01% Triton X-100, centrifuged again and monitored for bound radioactivity as described above. Data from saturation curves were analyzed using the non-linear least-squares curve-fitting program LIGAND (P.J. Munson and D. Rodbard, Anal. Biochem. 107:220 (1980)). This program has the distinct advantage of fitting the raw experimental data on an untransformed coordinate system where errors are most likely to be normally distributed and uncorrelated with the independent variable. LIGAND does not expect the non-specific binding to be defined arbitrarily by the investigator.
rather it estimates the value as an independent variable from the entire data set. The parameters for the affinity constants (K_D) and receptor densities (B_max) are also provided along with statistics on the general "fit" of the estimated parameters to the raw data. This program also offers the versatility of analyzing multiple curves simultaneously, thus improving the reliability of the data analysis and hence the validity of the final estimated parameters for any saturation experiment.

**Competition Curve Analysis**

In competition studies, 100 µl [125I] ovine CRF ([125I] oCRF; final concentration 200 - 300 pM) was incubated along with 100 µl buffer (in the presence of varying concentrations of competing ligands, typically 1 pM to 10 mM) and 100 µl of membrane suspension as prepared above to give a total reaction volume of 300 µl. The reaction was initiated by the addition of membrane homogenates, allowed to proceed to equilibrium for 2 h at 22°C and was terminated by centrifugation (12,000 x g) in a Beckman microfuge to separate the bound radioligand from free radioligand. The resulting pellets were surface washed twice by centrifugation with 1 mL of ice-cold phosphate buffered saline and 0.01% Triton X-100, the supernatants discarded and the pellets monitored for radioactivity at approximately 80% efficiency. The level of non-specific binding was defined in the presence of 1 mM unlabeled rat/humanCRF (r/hCRF). Data from competition curves were analyzed by the program LIGAND. For each competition curve, estimates of the affinity of the radiolabeled ligand for the CRF receptor ([125I]CRF) were obtained in independent saturation experiments and these estimates were constrained during the analysis of the apparent inhibitory constants (K_i) for the peptides tested. Routinely, the data were analyzed using a one- and two-site model comparing the "goodness of fit" between the models in order to accurately determine the K_i. Statistical analyses provided by LIGAND allowed the determination of whether a single-site or multiple-site model should be used.
For both peptides (α-helical CRF$_{9-41}$ and d-PheCRF$_{12-41}$), as well as for all compounds of this invention, data were fit significantly to a single site model; a two-site model was either not possible or did not significantly improve the fit of the estimated parameters to the data.

The results of the *in vitro* testing of the compounds of the invention are shown in Table 17. It was found, for a representative number of compounds of the invention, that either form of the compound, be it the free-base or the hydrochloride salt, produced essentially the same inhibition value in the binding assay.

A compound is considered to be active if it has an $K_i$ value of less than about 10000 nM for the inhibition of CRF. In Table 17, the $K_i$ values were determined using the assay conditions described above. The $K_i$ values are indicated as follows: ++ = $<500$ nM; ++ = 501-2000 nM; + = 2001-10000 nM.

Inhibition of CRF-Stimulated Adenylate Cyclase Activity

Inhibition of CRF-stimulated adenylate cyclase activity was performed as described by G. Battaglia et al., Synapse 1:572 (1987). Briefly, assays were carried out at 37°C for 10 min in 200 mL of buffer containing 100 mM Tris-HCl (pH 7.4 at 37°C), 10 mM MgCl₂, 0.4 mM EGTA, 0.1% BSA, 1 mM isobutylmethylxanthine (IBMX), 250 units/mL phosphocreatine kinase, 5 mM creatine phosphate, 100 mM guanosine 5'-triphosphate, 100 nM oCRF, antagonist peptides (concentration range 10⁻⁹ to 10⁻⁶M) and 0.8 mg original wet weight tissue (approximately 40-60 mg protein). Reactions were initiated by the addition of 1 mM ATP/³²P]ATP (approximately 2-4 mCi/tube) and
terminated by the addition of 100 mL of 50 mM Tris-HCl, 45 mM ATP and 2% sodium dodecyl sulfate. In order to monitor the recovery of cAMP, 1 μl of [3H]cAMP (approximately 40,000 dpm) was added to each tube prior to separation. The separation of [32P]cAMP from [32P]ATP was performed by sequential elution over Dowex and alumina columns. Recovery was consistently greater than 80%.

Representative compounds of this invention were found to be active in this assay. IC<sub>50</sub> ≤ 10,000 nanomolar.

In Vivo Biological Assay

The in vivo activity of the compounds of the present invention can be assessed using any one of the biological assays available and accepted within the art. Illustrative of these tests include the Acoustic Startle Assay, the Stair Climbing Test, and the Chronic Administration Assay. These and other models useful for the testing of compounds of the present invention have been outlined in C.W. Berridge and A.J. Dunn Brain Research Reviews 15:71 (1990).

Compounds may be tested in any species of rodent or small mammal. Disclosure of the assays herein is not intended to limit the enablement of the invention.

The foregoing tests results demonstrate that compounds of this invention have utility in the treatment of imbalances associated with abnormal levels of corticotropin releasing factor in patients suffering from depression, affective disorders, and/or anxiety. The foregoing tests also demonstrate that compounds of this invention have utility in the treatment of uterine contraction disorders.

Compounds of this invention can be administered to treat said abnormalities by means that produce contact of the active agent with the agent's site of action in the body of a mammal. The compounds can be administered by any conventional means available for use in conjunction with
pharmaceuticals either as individual therapeutic agents or in a combination of therapeutic agents. They can be administered alone, but are generally administered with a pharmaceutical carrier selected on the basis of the chosen route of administration and standard pharmaceutical practice.

The dosage administered will vary depending on the use and known factors such as the pharmacodynamic character of the particular agent, and its mode and route of administration; the recipient's age, weight, and health; nature and extent of symptoms; kind of concurrent treatment; frequency of treatment; and desired effect. For use in the treatment of said diseases or conditions, the compounds of this invention can be orally administered daily at a dosage of the active ingredient of 0.002 to 200 mg/kg of body weight. Ordinarily, a dose of 0.01 to 10 mg/kg in divided doses one to four times a day, or in sustained release formulation is effective in obtaining the desired pharmacological effect.

Dosage forms (compositions) suitable for administration contain from about 1 mg to about 100 mg of active ingredient per unit. In these pharmaceutical compositions, the active ingredient will ordinarily be present in an amount of about 0.5 to 95% by weight based on the total weight of the composition.

The active ingredient can be administered orally in solid dosage forms, such as capsules, tablets and powders; or in liquid forms such as elixirs, syrups, and/or suspensions. The compounds of this invention can also be administered parenterally in sterile liquid dose formulations.

Gelatin capsules can be used to contain the active ingredient and a suitable carrier, such as, but not limited to, lactose, starch, magnesium stearate, steric acid, or cellulose derivatives. Similar diluents can be used to make compressed tablets. Both tablets and capsules can be manufactured as sustained release products to provide for continuous release of medication over a period of time. Compressed tablets can be sugar-coated or film-coated to mask any unpleasant taste, or used to protect the active ingredients from the
atmosphere or to allow selective disintegration of the tablet in the gastrointestinal tract.

Liquid dose forms for oral administration can contain coloring or flavoring agents to increase patient acceptance.

In general, water, pharmaceutically acceptable oils, saline, aqueous dextrose (glucose), and related sugar solutions and glycols, such as propylene glycol or polyethylene glycol, are suitable carriers for parenteral solutions. Solutions for parenteral administration preferably contain a water soluble salt of the active ingredient, suitable stabilizing agents, and if necessary, buffer substances. Antioxidizing agents, such as sodium bisulfite, sodium sulfite, or ascorbic acid, either alone or in combination, are suitable stabilizing agents. Also used are citric acid and its salts, and EDTA. In addition, parenteral solutions can contain preservatives such as benzalkonium chloride, methyl- or propyl-paraben, and chlorobutanol.

Suitable pharmaceutical carriers are described in "Remington's Pharmaceutical Sciences", A. Osol, a standard reference in the field.

Useful pharmaceutical dosage-forms for administration of the compounds of this invention can be illustrated as follows:

Capsules

A large number of units in the form of capsules are prepared by filling standard two-piece hard gelatin capsules each with 100 mg of powdered active ingredient, 150 mg lactose, 50 mg cellulose, and 6 mg magnesium stearate.

Soft Gelatin Capsules

A mixture of active ingredient in a digestible oil such as soybean, cottonseed oil, or olive oil is prepared and injected by means of a positive displacement into gelatin to form soft gelatin capsules containing 100 mg of the active ingredient. The capsules are washed and dried.
Tablets

A large number of tablets are prepared by conventional procedures so that the dosage unit is 100 mg active ingredient, 0.2 mg of colloidal silicon dioxide, 5 mg of magnesium stearate, 275 mg of microcrystalline cellulose, 11 mg of starch, and 98.8 mg lactose. Appropriate coatings may be applied to increase palatability or delayed adsorption.

The compounds of this invention may also be used as reagents or standards in the biochemical study of neurological function, dysfunction, and disease.

Where the terms “comprise”, “comprises”, “comprised” or “comprising” are used in this specification, they are to be interpreted as specifying the presence of the stated features, integers, steps or components referred to, but not to preclude the presence or addition of one or more other feature, integer, step, component or group thereof.

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. **Claims Nos.:**
   - because they relate to subject matter not required to be searched by this Authority, namely:
     - Although claim 9 is directed to a method of treatment of the human body, the search has been carried out and based on the alleged effects of the compounds.

2. **Claims Nos.:**
   - 1 - 7 (searched incompletely)
   - because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
     - As the drafting of claims 1-7 is not clear and concise (Art. 6, PCT), and includes a considerably long list of substituents cascading amongst themselves with many disclaimers, a complete search is not possible on economic grounds (chapt. III, 2,1). So the search has been limited to the examples.

3. **Claims Nos.:**
   - because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

This International Searching Authority found multiple inventions in this international application, as follows:

1. **As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.**

2. **As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.**

3. **As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:**

4. **No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:**

**Remark on Protest**
- The additional search fees were accompanied by the applicant's protest.
- No protest accompanied the payment of additional search fees.
