COMMONWEALTH OF AUSTRALIA

Patents Act 1952-1973

APPLICATION FOR A PATENT

of

317 George Street, New Brunswick, New Jersey 08903, U.S.A.

hereby apply for a grant of a Patent for an invention entitled:

ABSORBENT NONWOVEN FABRIC CONTAINING STAPLE LENGTH CONJUGATE FIBERS AND SHORT NATURAL CELLULOSE FIBERS

which is described in the accompanying complete specification.

This Application is a Convention Application and is based on the Application(s) numbered: 282,325; 327,836 and 383,260

for a Patent or similar protection made in U.S.A. (all 3)

on 10 July 1981; 7 December 1981 and 2 June 1982, respectively.

Our address for service is care of GRIFFITH HASSEL & FRAZER, Patent Attorneys of 71 York Street, Sydney 2000, in the State of New South Wales, Commonwealth of Australia.

Dated this 6th day of July 1982

CHICOPEE

By their Patent Attorneys
CHIC 649

ASSIGNEE - APPLICANT

COMMONWEALTH OF AUSTRALIA

PATENTS ACT 1952 (AS AMENDED)

DECLARATION IN SUPPORT OF AN APPLICATION FOR A PATENT

8 5 6 8 6 / 8 2

(Name of applicant)

In support of an Application made by:

CHICOPEE

for a patent for an invention entitled: ABSORBENT NONWOVEN FABRIC CONTAINING STAPLE LENGTH CONJUGATE FIBERS AND SHORT NATURAL CELLULOSE FIBERS

(Signatory)

1. Charles J. Metz

(Address of signatory)

of 317 George Street, New Brunswick, New Jersey, USA

I do solemnly and sincerely declare as follows:

1. I am authorised by the above mentioned applicant for the patent to make this Declaration on its behalf.

2. The name and address of each actual inventor of the invention is as follows:

1. Paul Fekete
   22 Watchung Road
   East Brunswick, New Jersey, USA

2. Alfred Thomas Mays
   6 Lynnefield Drive
   East Windsor, New Jersey, USA

and the fact(s) upon which the applicant is entitled to make this application are as follows: Assignments dated:

July 8, 1981 (CHIC 637); December 3, 1981 (CHIC 645)
and June 1, 1982 (CHIC 649); each assignment assigning the invention from the inventors to the applicant.

3. The basic application(s) as defined by Section 141 of the Act was(ware) made as follows:

Country United States of America .............. on July 30, 1981, (CHIC 637)
in the name(s) Paul Fekete and Alfred Thomas Mays ...........................................
and in United States of America .............. on December 7, 1981, (CHIC 645)
in the name(s) Paul Fekete and Alfred Thomas Mays ...........................................
and in United States of America .............. on June 2, 1982, (CHIC 649)
in the name(s) Paul Fekete and Alfred Thomas Mays ...........................................

4. The basic application(s) referred to in the preceding paragraph of this Declaration was(ware) the first application(s) made in a Convention country in respect of the invention the subject of this application.

(Please and date of signing)

Declared at Piscataway, New Jersey, USA

this 7 day of June 1982

Signed: Charles J. Metz
Position: Assistant Secretary

GRiffith HasSEl & FraZER, P.O. BOX 2133, G.P.O., SYDNEY, NSW 2001 AUSTRALIA
Claim

1. An absorbent, thermal bonded nonwoven fabric having a bulk density below about 0.15 gram per cubic centimeter, said fabric comprising absorbent fibers and staple length conjugate fibers, said conjugate fibers being composed of polyethylene and polyester, wherein a substantial portion of the surfaces of said conjugate fibers comprises said polyethylene.

37. Process which comprises:

(a) producing a web comprising absorbent fibers and staple length conjugate fibers, said conjugate fibers being composed of polyethylene and polyester, wherein a substantial portion of the surface of said conjugate fibers comprises said polyethylene;

(b) subjecting said web to temperature sufficient to fuse said polyethylene without fusing said polyester, while maintaining said web under minimal pressure; and

(c) cooling said web to re-solidify said polyethylene, to thereby produce a low density, highly absorbent, thermal bonded nonwoven fabric.
The fabric resists attack by the solvents, cleaning emulsions, and other liquids encountered in use;
The invention relates to a low density, highly absorbent, thermal bonded nonwoven fabric comprising absorbent fibers and staple length polyethylene/polyester conjugate fibers, and to a process for making said nonwoven fabric.

**Background of the Invention**

Absorbent low density nonwoven fabrics have wide utility for use in catamenial devices such as panty shields, in absorbent pads and bandages, as wipes, and in similar applications. There is continuing interest in producing such nonwoven fabrics having higher absorption capacity and in producing such fabrics by methods that use less energy. The present invention provides such a nonwoven fabric having very high absorbent capacity, and which can be made by using a minimum of energy.

**The Prior Art**

Samejima, in U.S. Patent No. 4,160,159, discloses an absorbent fabric containing wood pulp and short length heat-fusible fibers, said fabric being supported on a web such as tissue paper. The web also contains powdered absorbent material distributed throughout. In producing the fabric, the heat-fusible fibers are fused, and thus the integrity of the heat-fusible fibers is destroyed.

(4) Tested on different samples from the same run.
Marshall, in U.S. Patent No. 4,083,913, also discloses a nonwoven fabric produced from short length heat-fusible fibers and absorbent fibers, wherein, again, in producing the final fabric, the heat-fusible fibers are fused and destroyed.

The fabric of the invention is a low density, highly absorbent, thermal bonded nonwoven fabric comprising absorbent fibers and staple length polyester/polyethylene conjugate fibers.

The nonwoven fabrics of the invention are produced by a process which comprises:

(a) producing a web comprising absorbent fibers and staple length polyester/polyethylene conjugate fibers;

(b) subjecting said web to a temperature sufficient to fuse the lower melting component of said conjugate fibers without fusing the higher melting component of said conjugate fibers, while maintaining said web under little or no compression; and

(c) cooling said web to resolidify the lower melting component of said conjugate fibers, to thereby form bonds at the sites where said conjugate fibers touch other fibers.
Brief Description of the Drawings

Fig. 1 is a schematic side elevation of an apparatus suitable for carrying out the process of the invention;

Fig. 2 is a perspective view of a catamenial device (panty shield) made from the nonwoven fabric of the invention;

Figs. 3 and 4 are perspective views of a wiping cloth made from the nonwoven fabric of the invention;

Figs. 5 and 6 are perspective views of a wound dressing made from the nonwoven fabric of the invention; and

Fig. 7 is a cross-section taken along line 7-7 of Fig. 5.

Detailed Description of the Invention

Referring first to Fig. 1, one preferred arrangement of apparatus for carrying out the process of the invention is displayed. The apparatus shown in Fig. 1 is suitable for making a nonwoven fabric of the invention comprising a core of a mixture of short-length natural cellulose fibers as the absorbent fibers and staple length polyester/polyethylene conjugate fibers, with a light weight veneer comprising heat-fusible fibers on both faces of the fabric. A light weight web is laid down, as from a card 12, on a first endless belt 14. A second web 16 comprising a mixture of short-length natural cellulose fibers and staple length polyester/polyethylene conjugate fibers is laid on a second endless belt 15. The second web 16 is produced in an air laying apparatus, for instance a dual rotor 18, such as is described by Ruffo and Goyal in U.S. Patent No. 3,768,118. The feed to the dual rotor 18 includes partially opened staple length polyester/polyethylene conjugate fibers fed...
through a chute feed 22, and a web of pulp sheet 24 composed of compacted wood pulp fibers, from a feed roll 26. The said second web 16 is fed onto the top of the lightweight web 10, to form a double layer web 28.

The double layer web 28 containing the web of heat-fusible fibers 10 on the bottom and the mixed web 16 on the top is then passed under another station wherein a second lightweight web of heat-fusible fibers 30 is laid on top, as from a card 32. The resulting triple layer web 34 is then passed through a through-air dryer 36 to fuse the lower melting component of the conjugate fibers while maintaining the integrity of these fibers as fibers, and to fuse or soften the surfaces of the heat-fusible fibers in the two veneers 10 and 30. When the triple layer web emerges from the dryer 36, it cools to thereby form the non-woven fabric 38 of the invention. When the web 36 cools, the fused surfaces of the heat-fusible fibers, and the fused lower melting component of the conjugate fibers, i.e., the polyethylene, solidify, and bonds then form where these surfaces touched other fibers. (By "other" fibers, is meant other heat-fusible and conjugate fibers as well as other types of fibers that may be present.) The fabric 38 is then collected on a conventional windup 40.

The thermal bonded nonwoven fabrics of the invention employ polyester/polyethylene conjugate fibers wherein at least about 50 per cent of the surface of the individual fibers is polyethylene. It is preferred to employ sheath/core fibers with the polyethylene as the sheath and the polyester as the core. Either eccentric or concentric sheath/core fibers can be employed. The fibers will usually have a denier within the range of from about 1 to about 6, and are usually in excess of about 1/2-inch in length, up to about 3 or 4 inches long.
Preferably, the conjugate fibers employ high density polyethylene, that is, linear polyethylene that has a density of at least about 0.94, and a Melt Index ("M.I.") by ASTM D-1238(E) (190°C, 2160 gms.) of greater than 1, preferably greater than about 10, and more preferably from about 20 to about 50. Usually the fibers will be composed of about 40 to 60 weight per cent, and preferably 45 to 55 weight per cent, polyester, the remainder being polyethylene.

The thermal bonded nonwoven fabrics of the invention also employ absorbent fibers, such as rayon staple fibers, cotton fibers, short length natural cellulose fibers such as wood pulp fibers and cotton linters, and mixtures thereof.

The absorbent fibers and the conjugate fibers are blended and formed into the feed web (e.g., 16 in Fig. 1) by standard methods. When the absorbent fibers include short length natural cellulose fibers, it is preferred to form the web by air laying, as by the use of the dual rotor disclosed, for instance, by Ruffo et al., in U.S. Patent No. 3,768,118.

When a veneer of heat-fusible fibers is used, it is preferred that said heat-fusible fibers also staple length conjugate fibers. However, if desired, other types of heat-fusible fibers such as polypropylene homofil fibers, can be used in the veneer. The veneer can also contain other fibers, such as rayon, cotton, or polyester staple fibers, that are not ordinarily heat-fusible.

The proportion of the polyester/polyethylene conjugate fibers in the web can vary from about 15 percent to about 75 percent (based on weight of conjugate fibers plus absorbent fibers), depending upon the end use intended for

9. The nonwoven fabric of claim 1 or 2 wherein said absorbent fibers are wood pulp fibers.
the fabric. The exact proportion has not been found to be narrowly critical.

If desired, other fibers can be included in the web, such as staple length polyester fibers, polypropylene fibers, and other known types of fibers.

The fabrics of the invention normally have basis weights from about 1/2 to about 6 ounces per square yard. The bulk density of the fabrics of the invention is usually below about 0.15 gram per cubic centimeter, preferably below about 0.09 gram per cubic centimeter, e.g., from about 0.02 to about 0.09 gram per cubic centimeter, and more preferably from about 0.025 to about 0.06 gram per cubic centimeter. The fabrics preferably have an absorbent capacity, as measured by a Gravimetric Absorbency Tester (described below, in the Examples), of at least 600 per cent and preferably at least 1400 per cent, exclusive of any non-absorbent layer such as a veneer of 100 per cent fusible fibers. The excellent resistance of the fabrics to wet collapse contributes to this high absorbent capacity. The bulk density and absorbent capacity figures disclosed here refer to the initial thermal bonded fabric, prior to any post treatment such as hot embossing, which can reduce the bulk density of the fabric.

The web of the invention is thermal bonded under conditions such that the integrity of the conjugate fibers is maintained. The purpose of maintaining the integrity of these fibers is to maintain the high loft or low bulk density characteristics of the finished nonwoven fabric, in order to achieve optimum absorption capacity and strength. The web is thermal bonded under conditions of zero pressure, or very light pressure, so that the web is not significantly crushed or compacted while the thermal bonding step is being carried out. The exact temperatures...
employed in the thermal bonding will vary, depending upon the weight and bulk density of the web, and the dwell time employed in the heated zone. The bonding temperature is usually from about 100°C to about 150°C. Dwell times in the heated zone will usually vary from about 2 seconds to about one minute. Specific conditions under which the thermal bonding is achieved are illustrated in the examples below. The temperatures referred to are the temperatures to which the fibers are heated in order to achieve bonding. In order to achieve high speed operations, much higher temperatures with short exposure times can be used. Routine experimentation will suffice to determine practical conditions.

In the thermal bonding step, the polyethylene, which is the lower melting component of the conjugate fiber, is at least partially fused so that where the fused surface touches another fiber, especially the fused surface of another conjugate fiber, welding or fusing together of the two fibers will occur. It is an important feature of this invention that the conjugate fibers remain fibers because the polyester does not melt, shrink, curl, or change its orientation during the thermal bonding step. This enables the thermal bonded fabric to maintain the bulk of the unbonded feed web.

The thermal bonding step can be carried out by through-air bonding, as is illustrated in Fig. 1 or by other means such as infrared heating or other type of radiant heating. Through-air heating can be accomplished by carrying the web on a porous conveyor belt through a zone where hot air is forced through the web, it can be carried through a heated zone contained between two porous belts, or it can be carried around a rotating drum having a porous surface which is equipped to suck hot air through the web as it is passing around the drum. The exact method of effecting the heating has not been found to be narrowly critical.
After the above-described thermal bonding, additional bonding and/or treatment of the web can be carried out. For instance, the fabric can be hot embossed to improve the overall integrity of the fabric, especially the surface abrasion resistance, to enhance utility in certain areas such as wiping.

In Fig. 2, a panty shield 42 made of the non-woven fabric of the invention is shown. Such panty shields are described in U.S. Patent Nos. 4,023,570 and 4,023,571.

The examples below illustrate various aspects of the invention.

Example 1

Using an apparatus similar to that shown in Fig. 1, a veneered fabric was made from wood pulp and Fiber A, a 2.5-3 denier bicomponent fiber, 1-1/2 inches long, having a high density polyethylene sheath and a polyester core, with the two polymers being present in a weight ratio of about 50/50. The polyethylene has a melt index of 42, a density of 0.96, and a DSC melting point of 132°C. The polyester is fiber grade polyethylene terephthalate. The fibers have a tenacity of about 3.3 grams per denier, an elongation of 30 to 60 per cent, and from 12 to 18 crimps per inch. The core was composed of about 70 weight per cent pulp fiber and 30 weight per cent Fiber A, and the two veneers were composed of Fiber A. One veneer weighed 160 grains per square yard, the other weighed 90 grains per square yard, and the entire fabric weighed 2.2 ounces per square yard. The fabric was through-air bonded by passing it around a honeycomb drier, which is a rotating drum adapted to suck hot air through the web. The temperature of the heated air was 340°F at the heater (a burner), and the recycled air had cooled to 200°F as it
entered the inlet side of the heater. Exposure time to the heated air was about 9 seconds. Certain physical properties of the fabric are displayed in Table I:

(1) Absorbent capacity measured on entire fabric, including veneer. Absorbent Capacity, as used herein, is the weight of deionized or distilled water absorbed, divided by the dry weight of the sample, multiplied by 100, as measured by a gravimetric absorbency tester ("GAT"), using a point source with the sample held on a horizontal plate. The sample was unloaded, i.e., no compression load was held on the sample.

The GAT is described in detail in commonly assigned U.S. patent application Serial No. 149,214, filed on May 12, 1980. Briefly, the GAT is an apparatus for determining the weight of liquid flowing to or from a test site. The apparatus comprises, in combination:

A vessel for containing liquid, said vessel being supported solely by weighing means;

Indicating means for indicating the weight sensed by said weighing means;

A test surface to receive a specimen to be tested, said test surface including said test site.
Conduit means operatively connecting said vessel to said test site for directing a flow of liquid between said vessel and said test site; and

Means for vertically positioning said test site.

The fabric of Example 1 was incorporated into a catamenial device and specifically the panty shield 42 illustrated in Fig. 2. The fabric comprised a layer 44 of absorbent material (i.e., the fabric of Example 1) which is to be placed against the body for absorbing body fluid. It will be understood that while a single ply of fabric is illustrated, the absorbent layer of fabric may be multiplied by using several sheets of fabric or by folding a sheet upon itself. A barrier film, layer 46, which may consist of a fluid impermeable film such as polyethylene, for example, is laminated to the absorbent material. Pressure-sensitive adhesive element 48 is placed on the face of the barrier film for adhering the panty shield 42 to the crotch of an undergarment. To protect the pressure-sensitive element 48 prior to use, a removable protective strip 50 is applied. The panty shield incorporating the fabric of this invention gives excellent performance.

Example 2

Using an apparatus similar to that shown in Fig. 1, two veneered fabrics were made from wood pulp and Fiber A. The veneers were all Fiber A. Both fabrics were bonded by placing them in a 300°F. oven, supported on a screen, for 30 seconds. Table II describes the two fabrics, and Table III displays certain properties of the fabrics:

Example 3

Using an arrangement of apparatus similar to that shown in Fig. 1 (with slight differences, as discussed below), a fabric designed for use as a plateroom wipe (a plateroom wipe is used in the offset printing industry to clean the printing plates and to apply developing emulsion) was produced as follows:
The fabric comprised a core with two veneers. Each veneer weighed 0.3 ounce per square yard and the core weighed 1.86 ounces per square yard. The compositions of each layer were as follows:

<table>
<thead>
<tr>

(2) Avtex 1913 rayon staple fiber having a staple length of 1-1/8 inches and a denier of 1.5.

(3) "Fortrel" 317 polyester staple fiber having a staple length of 1-1/2 inches and a denier of 1.5.

The bottom veneer was laid down as shown in Fig. 1. The core was laid down by a dual rotor, with the two staple fibers being fed to the dual rotor by two cards, and the pulp being fed in the form of pulp board. The top veneer was then laid down, as shown in Fig. 1. The web was through-air bonded by the honeycomb drier described in Example 1. The temperature of the heated air was 160° - 190°C. Exposure time to the heated air was about 2 1/2 seconds. After through-air bonding, the fabric was hot embossed by passing the fabric through the nip of a pair.
of counterrotating rolls, one roll being smooth and the other having a raised diamond pattern composed of two sets of raised parallel lines that intersected each other. Each set of lines was angled 30° from the machine direction to form a pattern of diamond-shaped parallelograms, each having two 60° angles and two 120° angles. Each line was 0.8 millimeter wide, 0.035 millimeter high, and the space between the lines (edge-to-edge) was 5 millimeters. The temperature of the rolls was 260°F., and the rolls were pressed together by a pressure cylinder operating at a pressure of 35 to 60 psig. The cylinder had a diameter of 2 centimeters, and the width of the web was about 17 inches.

A plateroom wipe 52 made from the fabric thus produced is shown in Figs. 3 and 4. The figures show the embossed lines 54 and the essentially three-layer construction comprising two veneers 56, 58 and a core 60.

The fabric described in this Example makes an excellent plateroom wipe for the following reasons:

a) It is soft and conformable;

b) It is absorbent;

c) It exhibits low linting;

d) It has high loft and bulk and retains these properties when wet;

e) While high strength is not required, the fabric retains adequate integrity and abrasion resistance during use;

f) The surface is not abrasive;
g) The fabric resists attack by the solvents, cleaning emulsions, and other liquids encountered in use;

h) The fabric is dimensionally stable; and

i) The embossed areas provide a place for dirt to collect. (The embossing also adds strength and integrity).

Some representative properties of the fabric described in Example 3 are shown below in Table V. The three samples were taken from different places during an extended run of the fabric.

(6) The GAT used a porous plate to hold the sample, instead of a point source, and the test liquid was 1% saline solution.

Example 4

A fabric designed for use in wound dressings or eye pads was produced by an arrangement of apparatus as shown in Fig. 1. The fabric had a core layer of pulp plus staple fiber and one veneer layer. The composition of the fabric was as follows:

<table>
<thead>
<tr>
<th></th>
<th>Table VI</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

The fabric was made by a procedure analogous to that described in Example 3, except that no embossing was carried out. The temperature and dwell time in the honeycomb drier were about 160° - 200°C. and about 3 seconds.

The fabric of this Example 4 was fabricated into a wound dressing 62, as shown in Figs. 5, 6, and 7. The dressing
was a three-layer structure made by superimposing three layers of fabric, and then sonically bonding the layers around the edges. The two outer layers 64, 66 were the fabric described above in this Example 4 (veneer sides 68, 70 out, as is shown in Fig. 7), with an inner layer 72 composed of a 1.5 oz/yd² through-air bonded web of 33% Fiber A and 67% Avtex 1913 rayon staple fibers.

The wound dressings made from the fabrics of this Example 4 exhibit the following desirable properties:

a) Good absorbent capacity; and

b) Ability to utilize a high proportion of the theoretical absorbent capacity of the dressing because of good horizontal wicking properties and the ability of the exterior face of the dressing to delay strike-through of aqueous liquids.

Table VII, below, displays some representative properties of the wound dressing described above:

<table>

(7) Test fluid was 1% saline with a red dye.

(8) The rate of liquid uptake in the GAT.

(9) The time for the test fluid to penetrate the exterior or top surface in the GAT test.
The claims defining the invention are as follows:

1. An absorbent, thermal bonded nonwoven fabric having a bulk density below about 0.15 gram per cubic centimeter, said fabric comprising absorbent fibers and staple length conjugate fibers, said conjugate fibers being composed of polyethylene and polyester, wherein a substantial proportion of the surfaces of said conjugate fibers comprises said polyethylene.

2. The nonwoven fabric of claim 1 wherein the bulk density of said fabric is within the range of from about 0.02 to about 0.09 gram per cubic centimeter.

3. The nonwoven fabric of claim 1 or 2 wherein said fabric has an absorbent capacity of at least about 1400 per cent.

4. The nonwoven fabric of claim 1 or 2 wherein at least one surface of said fabric has a veneer of thermal bonded heat-fusible fibers.

5. The nonwoven fabric of claim 3 wherein at least one surface of said fabric has a veneer of thermal bonded heat-fusible fibers.

6. The nonwoven fabric of claim 1 or 2 wherein the conjugate fibers are sheath/core bicomponent fibers.

7. The nonwoven fabric of claim 4 wherein said heat-fusible fibers are conjugate fibers.

8. The nonwoven fabric of claim 5 wherein said heat-fusible fibers are conjugate fibers.
9. The nonwoven fabric of claim 1 or 2 wherein said absorbent fibers are wood pulp fibers.

10. The nonwoven fabric of claim 3 wherein said absorbent fibers are wood pulp fibers.

11. The nonwoven fabric of claim 4 wherein said absorbent fibers are wood pulp fibers.

12. The nonwoven fabric of claim 7 wherein said absorbent fibers are wood pulp fibers.

13. The nonwoven fabric of claim 1 or 2 wherein the absorbent fibers are rayon staple fibers.

14. The nonwoven fabric of claim 3 wherein the absorbent fibers are rayon staple fibers.

15. The nonwoven fabric of claim 4 wherein the absorbent fibers are rayon staple fibers.

16. The nonwoven fabric of claim 5 wherein the absorbent fibers are rayon staple fibers.

17. The nonwoven fabric of claim 6 wherein the absorbent fibers are rayon staple fibers.

18. The nonwoven fabric of claim 7 wherein the absorbent fibers are rayon staple fibers.

19. The nonwoven fabric of claim 1 or 2 wherein said fabric contains staple length polyester fibers.

22. The nonwoven fabric of claim 7 wherein said fabric contains staple length polyester fibers.

27. The nonwoven fabric of claim 1 or 2 wherein said fabric is hot embossed.

28. The nonwoven fabric of claim 4 wherein said fabric is hot embossed.

29. The nonwoven fabric of claim 5 wherein said fabric is hot embossed.

30. The nonwoven fabric of claim 7 wherein said fabric is hot embossed.

31. The nonwoven fabric of claim 9 wherein said fabric is hot embossed.

32. The nonwoven fabric of claim 11 wherein said fabric is hot embossed.
33. The nonwoven fabric of claim 13 wherein said fabric is hot embossed.

34. The nonwoven fabric of claim 15 wherein said fabric is hot embossed.

35. The nonwoven fabric of claim 19 wherein said fabric is hot embossed.

36. The nonwoven fabric of claim 21 wherein said fabric is hot embossed.

37. Process which comprises:
   
   (a) producing a web comprising absorbent fibers and staple length conjugate fibers, said conjugate fibers being composed of polyethylene and polyester, wherein a substantial proportion of the surface of said conjugate fibers comprises said polyethylene;
   
   (b) subjecting said web to temperature sufficient to fuse said polyethylene without fusing said polyester, while maintaining said web under minimal pressure; and
   
   (c) cooling said web to re-solidify said polyethylene, to thereby produce a low density, highly absorbent, thermal bonded nonwoven fabric.

38. Process of claim 37 wherein said web includes at least one veneer layer comprising heat-fusible fibers.

39. Process of claim 37 or 39 wherein the nonwoven fabric product of step (c) is subjected to the additional step of hot embossing.
40. A catamenial device comprising the nonwoven fabric of claim 1.

41. The catamenial device of claim 40 comprising the nonwoven fabric of claim 1 having laminated thereto an impermeable layer, said impermeable layer having applied thereon a pressure-sensitive adhesive element for adhering to an undergarment, said pressure-sensitive element having a protective layer to protect the same prior to use.
