Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European patent convention.)

Description

The present invention relates to a control device for a pneumatically-driven demand pump used in a post-mixed beverage dispenser system for pumping syrup from a syrup supply to a dispenser nozzle. The control device comprises a surge suppressor for suppressing surges of the flow of syrup output from the pump. The surge suppressor comprises a pressure sensor coupled to a valve actuator means and a biasing means.

Such a control device is known from AT--B--1097. This known control device shuts off the flow of gas to the pneumatically-driven demand pump when the pressure of the liquid sensed by the pressure sensor rises above a predetermined value. Such pressure enhancement may be caused for example by interruption of the liquid delivery. No provisions are taken for the case that the pressure of the liquid drops below a predetermined limit or the liquid supply is interrupted for example due to the liquid container being empty. In such a case, the demand pump would continue to work.

FR--A--2,947,543 discloses a liquid pump comprising a pressure sensor which shuts off the pump when the pressure in the outlet conduit goes beyond an adjusted upper limit.

Diaphragm pumps are widely used, particularly for pumping liquid solutions and highly viscous materials under conditions such that the viscosity of the fluid being pumped, the head on the suction side of the pump and the back pressure on the pump discharge may all vary depending on the use of the pump. An example of such a pump is disclosed in US--A--3,741,688. This pneumatically-powered demand pump normally continues to pump until a predetermined outlet pressure is reached. The pump will continue to pump a particular fluid, such as syrup, until the inlet gas pressure to the pump from the pneumatic power supply can no longer overcome the fluid pressure in the outlet line of the pump. When the suction line of a demand pump is connected to an empty, nonvented container, the pump is unable to suck enough fluid so as to pressurize the outlet line to a level above the aforementioned inlet gas pressure, so the pump cannot turn itself off. Thus, the pump will dry cycle indefinitely under these circumstances, wasting gas and possibly damaging the pump. This condition can develop due to a blocked or defective suction line or an empty syrup supply package.

On occasions during the operation of a pneumatically-powered demand pump, a partially blocked or defective suction line may produce surging of the liquid being pumped. Such a condition leads to uneven supply of the liquid medium and poor quality control of the product produced. Although certain devices have been proposed which control and regulate the air input to such a pneumatically-powered system, in most instances these devices are electrically powered or vacuum operated. In the case of an electrically powered control device, the requirement for the use of electricity inherently is a negative feature, increasing the cost of the operation. The use of a vacuum sensing device at the pump inlet will only work with sealed, non-vented containers and will not work with vented containers. Vacuum sensing control devices also do not work well when used in conjunction with other vacuum-operated devices such as vacuum-operated switchover valves which are frequently used in syrup dispensing systems.

The invention as claimed in claim 1 solves the problem of how to provide a pneumatically-powered demand pump which protects the pump from overworking.

The control device is suited for controlling the pneumatic input to pneumatically-powered demand pump which works well with both vented and non-vented liquid supply containers and which is actuated by pressure changes and the liquid output from the pump and operates reliably over a broad range of flow conditions.

Movements of the surge-suppressor means are accompanied by movements of the same distance by the valve sealing element because the valve stem is coupled to both the surge-suppressor means and the sealing element of said valve.

The surge-suppressor means is preferably a flexible diaphragm hermetically mounted in an opening in a side wall of said first conduit means and movable transversely thereof in response to liquid pressure changes therein. The diaphragm is attached to one end of the valve stem. A coil spring biases the valve stem and the diaphragm inwardly of the first conduit to suppress liquid surges therein. The spring also functions to close the valve sealing element when the liquid pressure in the first conduit drops below a predetermined minimum.

The valve sealing element may be an O-ring on the valve stem or preferably another flexible diaphragm similar to the surge-suppressor diaphragm.

A manual priming (override) lever is provided at the opposite end of the valve stem from the surge-suppressor diaphragm. The priming lever may be manually moved to open the valve to permit the flow of gas to the pump until the liquid or syrup pressure at the pump outlet is high enough to hold the valve open.

The invention is further illustrated by way of the accompanying drawings, wherein:

Figure 1 is a schematic diagram showing the interrelationship between the flow control device of the present invention and a representative pump and fluid dispensing system;

Figure 2 represents a side sectional view of one embodiment of a flow control device of the present invention;

Figure 3 is an end elevational view of the right side of the device of Figure 2; and

Figure 4 is a preferred embodiment of a control device of the present invention.

The functions of the control device of the present invention can be best understood by
reference to the schematic diagram of Figure 1, illustrating the control device 10 in circuit with a pneumatically-powered (air-powered) demand pump 41. Pump 41 may be any suitable reciprocating diaphragm pump such as disclosed in US—A—3,741,689; 4,123,204; and 4,172,698.

Such a pump typically includes a reciprocating shaft S connected between a pair of diaphragms Da, Db in pump chambers 41a, 41b, respectively. Gas to drive the pump is alternately supplied to the inboard sides of diaphragms Da, Db by a reversing valve 44 via lines 45a, 45b. As the pump reciprocates liquid in chambers 41a, 41b on the outboard sides of diaphragms Da, Db is alternately discharged through outlet check valves CVO. Reversing valves suitable for use as valve 44 are also disclosed in the aforementioned pump patents.

Figure 1 illustrates a pump 41 of the above-described type in fluid circuit with a post-mix beverage dispensing system. The flow control device 10 of the present invention is connected between the pump output check valves CVO and a plurality of post-mix beverage dispenser nozzles 42 (42a, 42b, 42n). Syrup is supplied to the pump chambers 41a, 41b through inlet check valves CVI. A syrup supply system 46 may include first and second groups of syrup sources 47, 48 coupled through a changeover valve 49. Examples of a semi-automatic changeover valve and associated bag-in-box syrup sources are described in US—A—4,275,823 and 4,014,461. These bag-in-box syrup sources 47, 48 are unvented and the bags thereof collapse to create a vacuum when empty. This vacuum is utilized to actuate the changeover valve 49. For this reason, prior art vacuum operated flow regulating control devices in fluid circuit with valve 49 on the input side of pump 41 cannot be effectively used to shut off the operation of pump 41 when the supply of syrup is depleted. This is, such a control device will interfere with the operation of changeover valve 49 and vice-versa. In contrast, the control device 10 of the present invention disposed on the output side of pump 41, will not interfere with the operation of valve 49.

In addition, the control device 10 will operate satisfactorily with vented syrup supply containers, if desired.

The control device 10 of the present invention includes: a first conduit 12 for accommodating the flow of syrup output from pump 41 via check valves CVO; fluid or syrup inlet 11; a fluid or syrup outlet 13; and a flexible diaphragm 28 for sensing pressure changes and suppressing surges of syrup in first conduit 12. Diaphragm 28 is coupled within control device 10 to a valve V disposed in a second conduit 16 for accommodating the flow of air from air supply 43 via air inlet 14. When syrup pressure in first conduit 12 is above a predetermined level, valve V is opened, permitting air from second conduit 16 to flow from air outlet 17 to reversing valve 44. The air is then alternately supplied through lines 45a, 45b to pump chambers 41a, 41b in the

fashion previously described to drive the pump 41.

However, when the pressure in the syrup in the first conduit 12 drops below a predetermined minimum, diaphragm 28 moves to close valve V, shutting down the supply of air to pump 41 and the pump 41 stops. Diaphragm 28 also functions to suppress surges of syrup flow from first conduit 12 to dispenser nozzles 42 in a manner to be described more fully hereinafter with reference to the specific embodiments of Figures 2 to 4.

Referring now to Figures 2 and 3, there is illustrated one embodiment of the flow control device 10. The syrup inlet 11, the first conduit 12 for accommodating the flow of syrup, and the syrup outlet 13 are integrally formed in an upper housing portion UH. The syrup inlet 11 of the flow control device 10 receives the syrup from a demand pump 41 and discharges it to the post-mix beverage dispenser nozzle 42. The air which drives the demand pump 41 enters control device 10 through the air inlet 14 in a lower housing portion LH, and is directed through a chamber 15 through the valve V opening to the air outlet 17 via the second conduit 16. The air passes to the demand pump 41 via reversing valve 44 of Figure 1 to drive the diaphragms Da, Db thereof to pump syrup through the first conduit 12. The lower housing portion LH also has a vertically disposed central bore B.

The valve V is provided within the lower housing bore B of the control device 10 and includes a valve stem 21, an O-ring valve sealing element 23 and a seat 24. O-ring seals 22, 25 are also provided on stem 21 and are supported by retaining flanges 21A, 21B and 21D, respectively. Flange 21C retains the O-ring valve sealing element 23 in place and is of small enough outside diameter to clear valve seat 24 when moved upwardly to close the valve.

A priming lever 27 is secured to the bottom of valve stem 21 and provides a means for manually overriding the control device when it is in the closed position. Lever 27, when depressed downwardly in the position illustrated in Figure 2, resets the control device 10 to permit the flow of air into the pump 41 until the syrup pressure output from the pump 41 is high enough to hold the valve sealing element 23 open.

Diaphragm 28 forms a pressure-sensitive element and has a flexible membrane 28M, which can be secured or not to a piston 28P, centrally secured to the top end of valve stem 21, and has peripheral portions of membrane 28M sandwiched between housing portions UH, LH. Diaphragm 28 responds to pressure changes within the first conduit 12 such that the valve sealing element 23 connected thereto will move in unison with, and an equal distance to, diaphragm 28.

The diaphragm 28, valve stem 21, and valve sealing element 23 are continuously biased upwardly by a coil spring 23, compressed between the bottom of the control device housing and flange 21A. If the pressure within the first
conduit 12 drops below a predetermined value, such as by a depletion of the syrup supply or a blocked or defective suction line, the spring 29, surrounding valve stem 21 and biased against flange 21A, will urge the valve sealing element 23 against the valve seat 24 to close off the flow of air from the air inlet 14 to the second conduit 16. Thus, when the flow of syrup ceases or is interrupted, the decrease in syrup pressure within the first conduit 12 causes the valve sealing element 23 to shut off the air flow which stops the cycling of the pump 41.

Depending upon the cause of the pressure decline, once syrup is again available to the suction line of the pump 41, the priming lever 27 is actuated or reset to the position shown in Figure 2, so as to reopen the valve sealing element 23. Once the pump outlet syrup pressure is high enough to hold the valve element 23 open, the priming lever 27 is released.

As discussed hereinbefore, the control device 10 of the present invention also serves as a surge-suppressor when used, for example, with a reciprocating air-powered pump. Small fluctuations or pulses may be smoothed out by the spring-loaded pressure-sensitive diaphragm 28 which moves transversely against the syrup in first conduit 12 to adjust the syrup pressure toward a constant value. The distance between the valve sealing element 23 and the valve seat 24, in a fully open valve position as illustrated in Figure 2, may be predetermined to control the size of the surge to be smoothed out before the air flow is completely shut off by valve sealing element 23. This is possible because diaphragm 28 and valve sealing element 23 move in unison over equal distances.

The control device 10 in the embodiment of Figures 2 and 3 also includes a vent port VT.

Figure 3 illustrates an end elevational view of the right side of the air flow control device 10 of Figure 2.

Referring to Figure 4, there is illustrated a preferred embodiment of the control device 10 of the present invention.

In this embodiment, the device 10 includes a three-piece housing including an upper housing portion UH, central housing portion CH and lower housing portion LH. The central bore B is defined by housing portions CH, LH. The air for driving the pump 41 enters through inlet 14 in central housing portion CH, and exits via second conduit 16 and outlet 17. The pressure-sensitive diaphragm 29 is sandwiched at its periphery between housing portions UH, CH, and has a centrally disposed plug-shaped projection 36 supported between flanges 51 on the top end of the valve stem 21, mounted for reciprocating movement in bore B. A second diaphragm 39, having a centrally disposed, plug-shaped projection 39A supported between flanges 52, is positioned at approximately the mid-point of valve stem 21 for sealing engagement with the valve seat 24. The periphery of diaphragm 39 is sandwiched between housing portions CH, LH. The coil spring, 29 is disposed in bore B in compression against flange 55 on valve stem 21, and thus biases valve stem 21 and diaphragms 28, 39 upwardly, as viewed in Figure 4. Therefore, a drop in pressure of syrup in conduit 12 below a predetermined level is sensed by pressure-sensitive diaphragm 28, and will permit spring 29 to shift the valve stem 21 axially in bore B so as to seat the plug-shaped projection 39A of second diaphragm 39 against valve seat 24. This closes off the air passage from the air inlet 14 to the air outlet 17 via second conduit 16, to stop the pump 41, as described hereinbefore. The configuration set forth in Figure 4 may be referred to as a double diaphragm type of air flow control device, since both the pressure-sensitive and valve-sealing elements are diaphragms.

The double diaphragm embodiment of Figure 4 is advantageous in that it does not require the O-ring seals, such as 22 and 25 of Figure 2, on the valve stem 21. Thus, the valve stem 21 can move more freely with less drag.

The diaphragm 28 of Figure 4 also functions as a surge-suppressor in the same manner as diaphragm 28 of Figure 2 in conjunction with the bias force of spring 29.

The embodiments of the flow control device of the present invention, as described in connection with Figures 1 to 4 function both as a surge suppressor for dampening small fluctuations or pulses within the liquid output from the pump, and for shutting off the pump, thus protecting the pump from rapid cycling and the accompanying unnecessary gas consumption when the supply of syrup at the pump inlet is depleted. This condition can be caused by an empty syrup supply unit or a blocked or defective suction line. In the former situation, the device of the present invention may function as a "sold-out" indicator which monitors the liquid capacity of its liquid (syrup) supply unit. In addition, due to the fact that the device is activated by pressure, not flow, it will function properly over a broad range of flow conditions. Also, the multiple-piece housing construction permits the device to be easily disassembled and sanitized. The compactness of the device also permits it to be directly mounted on an associated pump.

**Claims**

1. Control device (10) for a pneumatically-driven demand pump (41) of a post-mix beverage dispenser system for pumping syrup between a syrup supply (47, 48) to a dispenser nozzle (42), comprising

   first conduit means (12) for accommodating the flow of syrup output from said pump (41);

   second conduit means (16) for accommodating the flow of gas to drive said pump (41);

   surge-suppressor means for suppressing surges of syrup flow through said first conduit means (12) caused by changes in pressure of said syrup, said surge suppressor means comprising a pressure sensor (28) movable inwardly of said first conduit means (12) and a biasing means (29),
said pressure sensor (28) being connected to the actuator (28P, 21) of a valve means (V) moving therewith in unison; characterized by the valve means (V) being arranged to shut off the flow of said gas through said second conduit means (16) when the pressure of said syrup sensed by said pressure sensor falls below a predetermined value,
said pressure sensor being a flexible member (28M) movable transversely to the flow of said syrup through said first conduit means (12) and manual means (27) for resetting said valve means (V) in an open position to permit the flow of said gas until the pressure is high enough to hold said valve means (V) open.

2. The device of claim 1 wherein said surge-suppressor means comprises a piston (28P) covered by a flexible membrane (28M) and said biasing means comprises a spring (23).

3. The device of any one of claims 1 or 2, wherein said valve means (V) comprises a movable diaphragm (39) operatively associated with a valve seat (24).

Patentansprüche

1. Steuervorrichtung (10) für eine pneumatisch angetriebene, bedarfsabhängig arbeitende Pumpe (41) eines Nachmisch-Getränkeausgabesystems zum Pumps von Sirup zwischen einem Sirupvorrat (47, 48) zu einer Ausgabedüse (42), mit
einer ersten Leitung (12), die die Strömung des von der Pumpe (41) ausgegebenen Sirups aufnimmt;
einer zweiten Leitung (16), die die Strömung des Gases zum Antrieb der Pumpe (41) aufnimmt;
einer Stoßunterdrückungseinrichtung zum Unterdrücken von Stößen der Sirupströmung durch die erste Leitung (12), die durch Änderungen im Druck des Sirups verursacht werden, wobei die Stoßunterdrückungseinrichtung einen Drucksensor (29), der einwärts der ersten Leitung (12) beweglich ist, und eine Vorspannungseinrichtung (29) aufweist, wobei der Drucksensor (28) mit dem Steigglied (28P, 21) eines Ventils (V) verbunden ist, das sich in Übereinstimmung mit diesem mitbewegt;
dadurch gekennzeichnet,
daß das Ventil (V) so angeordnet ist, daß es die Strömung des Gases durch die zweite Leitung (16) unterbricht, wenn der von dem Drucksensor wahrgenommene Sirupdruck unter einen vorgegebenen Wert fällt;
daß der Drucksensor ein flexibles Element (28M) ist, das quer zur Strömung des Sirups durch die erste Leitung (12) beweglich ist, und daß eine Handhabe (27) zum Rücksetzen des Ventils (V) in eine offene Position vorgesehen ist, um dadurch die Strömung des Gases zu ermöglichen, bis der Sirupdruck hoch genug ist, um das Ventil (V) offenzuhalten.

2. Vorrichtung nach Anspruch 1, wobei die Stoßunterdrückungseinrichtung einen Kolben (28P) aufweist, der von einer flexiblen Membran (28M) bedeckt ist, und die Vorspannungseinrichtung eine Feder (29) aufweist.

3. Vorrichtung nach einem der Ansprüche 1 oder 2, wobei das Ventil (V) eine bewegliche Zwischenmembran (39) aufweist, die einem Ventilsitz (24) betriebmäßig zugeordnet ist.

Revendications

1. Dispositif de commande (10) pour une pompe de distribution (41) entraînée pneumatiquement d'un système distributeur de boisson en post-mélange pour pomper du sirop entre une source de sirop (47, 48) et une buse de distribution (42), comprenant:
— un premier conduit (12) pour recevoir l'écoulement de sirop débité par la pompe (41);
— un second conduit (16) pour recevoir l'écoulement de gaz servant à entraîner ladite pompe (41);
— un moyen de suppression d'â-coups pour supprimer des â-coups dans l'écoulement de sirop passant dans ledit premier conduit (12) et causés par des variations de pression dudit sirop,
— ledit moyen de suppression d'â-coups comprenant un détecteur de pression (28) déplaçable à l'intérieur dudit premier conduit (12) et un moyen de poussée (29), ledit détecteur de pression (28) étant relié à l'organe d'actionnement (28P, 21) d'une valve (V) se déplaçant avec lui à l'unisson;
— caractérisé par le fait que
— la valve (V) est agencée de manière à arrêter l'écoulement dudit gaz dans ledit second conduit (16) quand la pression dudit sirop détectée par ledit détecteur de pression descend en dessous d'une valeur prédéterminée,
— ledit détecteur de pression est un élément flexible (28M) déplaçable transversalement à l'écoulement dudit sirop dans ledit premier conduit (12), et
— il est prévu un moyen Manuel (27) pour ramener ladite valve (V) dans une position d'ouverture afin de permettre l'écoulement dudit gaz jusqu'à ce que la pression du sirop soit suffisamment grande pour maintenir ladite valve (B) ouverte.

2. Le dispositif selon la revendication 1, dans lequel ledit moyen de suppression d'â-coups comprend un piston (28P) couvert par une membrane flexible (28M) et ledit moyen de poussée comprend un ressort (29).

3. Le dispositif selon une quelconque des revendications 1 ou 2, dans lequel ladite valve (V) comprend un diaphragme mobile (39) associé fonctionnellement avec un siège de valve (24).
FIG. 1
