Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).
Description

Hot melt compositions and methods for forming the same are well known in the art.

The prior art as illustrated by the identified patents deal with urethane thermoplastic elastomer, molding compounds, gasketing and other areas -- none of these patents nor other literature or additional prior art denotes materials having low melt viscosity, elastomeric materials with high physical properties and melt stability.

The identified patents are:

US-A-3,886,182 describes thermosetting (rapid setting or instant set), non-elastomeric plasticized urethane molding compounds with a polylol functionality of 3-8. The main purpose of the plasticizer is to make the compound readily demoldable.

US-A-3,684,693 deals with textile sealing adhesives dealing with specific polyglycols and an aliphatic isocyanate. Differences are that it pertains to an unplasticized composition normally polymerized in solution or applied as a powder. Although the invention deals with thermoplastics, they are not hot metal materials.

US-A-3,834,578 deals with liquid casting urethanes useful for foamy gaskets, but not applied as hot melt, does not contain plasticizers and the rest of the chemistry is also not similar.

US-A-3,640,937 deals with linear elastomer fibers composed of specific dihydrazide chain extenders. The reaction is carried out in solvents and does not contain plasticizers.

US-A-3,289,946 deals with a foam molding compound not a thermoplastic hot melt compound. Liquid reactants are used in the process and the final product is a solid material.

US-A-4,101,438 deals with a thermoplastic composition containing no plasticizer and does not function as a hot melt material.

US-A-4,349,640 discloses a process for forming a hot melt composition wherein a diisocyanate-prepolymer, a polylol, a chain extender and a plasticizer are mixed at a temperature of up to 93°C.

According to the invention there is provided a process for forming a hot melt composition comprising a polyurethane having at least one plasticiser reacted therein formed from at least one isocyanate having a functionality less than 2.2, at least one long chain polylol having a number average molecular weight of more than 500 to 5000 and an average functionality of 2.2 or below, at least one chain extender and at least one plasticiser characterised by heating a mixture of the above-named components at a temperature of at least 165°C, wherein said components are present in an amount to meet the following formula:

\[ A + B + C = 0.5 \text{ to } 7.0 \]

\[ D \]

wherein:

A represents the equivalent weight of the long chain polylol x the number of moles thereof used;

B represents the equivalent weight of the chain extender x the number of moles thereof used;

C represents the equivalent weight of the isocyanate x the number of moles thereof used; and

D represents the number of grams of plasticiser.

The one or more plasticizers react into the system and, based on results to date, cannot be extracted therefrom or are only partially extractable by common organic solvents at normal end use of the conditions hot melt material, e.g., hexane, gasoline, motor oil, etc.

Per the present invention, the hot melt compositions, it has been found, must be elevated prior to or during use to a temperature of at least 165°C (330°F) to obtain the hot melt characteristics required per the present invention.

Normally we use an initial processing temperature of at least 165°C (330°F) where plasticizer reaction into the polyurethane is substantially completed simultaneously with achievement of the requisite temperature of 165°C (330°F).

However, as Example 6 establishes, it is also possible to simply blend all components of the hot melt composition, permit the same to in situ cure, and then, prior to or during use, elevate the temperature thereof to at least 165°C (330°F).

While the heating time varies greatly, without being subjected to a process cycle at a temperature of at least 165°C (330°F), prior to or during actual end use, the hot melt characteristics required are not realized.

With respect to heating time, this varies greatly depending upon the form of the hot melt composition. For example, assuming a substantially completely cured thin film or layer thereof (e.g., permitted to in situ
cure in place or in a container for a substantial period of time), our results indicate that heating to at least 165°C (330°F) for a period of, for example, on the order of three minutes provides the desired hot melt characteristics. On the other hand, where a larger batch of initial reactants is involved (e.g., a 3:6 to 1800 l [1 to 500 gallon] batch), we normally heat to at least 165°C (330°F) for at least about two hours to form the resultant hot melt composition.

In the former case, the end user will often be the individual to actually perform the step of temperature elevation to at least 165°C (330°F), whereas in the latter case normally the initial manufacture will form the hot melt composition which need not be later heated to a temperature of at least 165°C (330°F) (though in fact it may be so heated without harm).

Obvious variations will be apparent to one skilled in the art, e.g., rather than an extended stand at ambient temperature one could use a lesser stay at an intermediate temperature or use a catalyst, but the key factor is to elevate the hot melt composition to at least 165°C (330°F) prior to or during use to transform the same from a "cottage cheese" like consistency to that of a hot melt composition. Thus, often we speak of a mandatory temperature elevation to at least 165°C (330°F). This is correct in that if we are manufacturing an "end use ready" product for use at less than 165°C (330°F) this temperature must be reached prior to use. However, dependent on the form of the hot melt composition at the time of use, e.g., thin film and the temperature of end use, initial processing can be at lower temperature. Also, if one wished to perform a temperature elevation intermediate mixing the components and end use, the temperature elevation should be to at least 165°C (330°F). Though we do not see this as commercially desirable, this is also contemplated per the present invention.

A hot melt composition per the present invention is generally one applied in the molten state and having a viscosity in that condition (Brookfield viscometer of less than 500 Ns/m² (50,000 cps), more preferably less than 250 Ns/m² (25,000 cps). When the hot melt composition is cooled to room temperature, of course, it is a solid which is elastomeric in nature.

The urethane materials of the present invention function as a hot melt material which can be used to form, e.g., adhesives, foamed gaskets, caulks, and, we believe, pourable casting materials, tank coatings and linings and hot melt paints.

The benefits and potential benefits of the urethane materials of the present invention arise from certain basic properties thereof, with the main property of interest being the ability of these materials to flow at a comparatively low temperature of application of 121°C (250°F) to 232°C (450°F) i.e., the viscosities within this temperature range allow the material to be poured and potentially to be sprayed.

Other beneficial properties include high strength, adhesion to many surfaces, stability at elevated temperatures, formability with good compression set, higher physical properties than amorphous systems since a crystallizable polymer is involved, good heat resistance up to 177°C (350°F) with some formulations, good elastomeric properties, low temperature flexibility, low energy use compared to many other adhesives, relatively fast development of strength, relatively good solvent resistance, good tear resistance, good impact resistance, relatively good oil resistance and water resistance, high abrasion resistance and good plasticizer migration resistance in a bonded part.

The urethane materials of the present invention are based on essentially stoichiometric amounts of a disocyanate (which will insure a thermoplastic material results) having a functionality of 2.2 or less, most preferably 2.15 or less, and most preferably in the range of 2.0-2.1. If the functionality is in excess of 2.2, a thermosetting material results. With certain isocyanates having a functionality close to 2.2 a thermosetting material can also result. Such are also excluded from the present invention. The difunctional isocyanate is reactive with materials containing an active hydrogen such as a hydroxyl, amine, and mercaptan group and others. These active species react with each other based upon their stoichiometry and equivalency. Basically, it requires a difunctional isocyanate to be reacted with a difunctional active hydrogen (in a hydroxyl group, for example) containing material to form a polymer.

It is to be understood, in accordance with the present invention, that essentially all percentages, etc., are conventional in the art except with respect to the plasticizer which, it is our belief, we utilize in percentages much higher than are commonly utilized in the art.

As earlier indicated, the most important aspect with respect to the polyisocyanates of the present invention is the functionality thereof. Accordingly, while we prefer to use 4,4-diphenyl methane disocyanate (MDI), the present invention is, in our belief, of broad application with respect to the polyisocyanates selected.

The polyisocyanate reactants useful in our invention are aromatic, aliphatic, cycloaliphatic or aralkyl polyisocyanates containing from 6 to 100 carbon atoms. Although the preferred isocyanate-containing reactants contain two isocyanate groups, reactants containing more than two such groups are operative so long as the average functionality does not exceed 2.2 and the resulting urethane is thermoplastic. Blends or
mixtures are also included in our general definition of diisocyanate. Isocyanate terminated prepolymer
which perform as diisocyanates under the conditions encountered in the process of our invention and have
an average functionality of 2.2 or less are also useful and are considered equivalent to the diisocyanates in
our invention.

A. Polyoxyalkylisocyanates

The following, among other polyisocyanates, are expected to be useful:
toluene-2,4-diisocyanate;
3-phenyl-2-ethylenediisocyanate;
1,5-naphthalene diisocyanate;
cumene-2,4-diisocyanate;
4-methoxy-1,3-phenylene diisocyanate;
4-chloro-1,3-phenylenediisocyanate;
4-bromo-1,3-phenylene diisocyanate;
4-ethoxy-1,3-phenylenediisocyanate;
2,4-diisocyanatodiphenyl ether;
5,6-dimethyl-1,3-phenylenediisocyanate;
2,4-dimethyl-1,3-phenylenediisocyanate;
4,4'-diisocyanatodiphenyl ether;
benzinediisocyanate;
4,6-dimethyl-1,3-phenylenediisocyanate;
9,10-anthracenediisocyanate;
4,4'-diisocyanatodibenzyl;
3,3'-dimethyl-4,4'-diisocyanatodiphenylmethane;
2,6-dimethyl-4,4'-diisocyanatodiphenyl;
2,4-diisocyanatostilbene;
3,3'-dimethyl-4,4'-diisocyanatodiphenyl;
3,3'-dimethoxy-4,4'-diisocyanatodiphenyl;
1,4-anthracenediisocyanate;
2,5-fluoroendisocyanate;
1,5-naphthalenediisocyanate;
1,3-phenylenediisocyanate;
methylene-bis(4-phenyisocyanate);
2,6-diisocyanatobenzylfuran;
bis(2-isocyanatoethyl)fumarate;
bis(2-isocyanatoethyl)carbonate; and
bis(2-isocyanatoethyl)-4-cyclohexene-1,2-dicarboxylate.

Representative monomeric aliphatic polyisocyanates which should be useful in the present invention
include, among others:
1,4-tetramethylenediisocyanate;
1,6-hexamethylenediisocyanate;
1,10-decamethylenediisocyanate;
1,3-cyclohexylenediisocyanate;
4,4'-methylene-bis(cyclohexylisocyanate); and
tetramethylenexylene diisocyanate (TMXDI).

The term aliphatic polyisocyanate as used herein includes any organic polyisocyanate in which the
isocyanato groups are attached to saturated carbon atoms. Cycloaliphatic polyisocyanates and
polyisocyanates containing aromatic rings such as xylylene diisocyanate can be used provided they meet
the limitation stated above. Representative aliphatic polyisocyanates which should be useful include 1,4-
tetramethylene diisocyanate; 1,6-hexamethylene diisocyanate; 2,2,4-trimethyl-1,6-hexamethylene
diisocyanate; m- and p-xylylene diisocyanate; 3-isocyanatomethyl-3,5,5-trimethycyclohexyl isocyanate;
phenylene bis(2-ethyl isocyanate); 4-methyl-1,3-cyclohexylene diisocyanate; 2-methyl-1,3-cyclohexylene
diisocyanate; 4,4'-methylene bis(cyclohexyl isocyanate) and 2,4'-methylene bis(cyclohexyl isocyanate). In
addition, aliphatic diisocyanates which contain ester linkages should be useful. Illustrative of such
isocyanates are bis(2-isocyanatoethyl)carbonate; bis(2-isocyanatoethyl)fumarate; bis(2-isocyanatoethyl)-4-
cyclohexene-1,2-dicarboxylate and lower alkyl esters of 2,5-diisocyanatovaleric acid. Polyisocyanates con-
taining three or more isocyanato groups per molecule such as 2,4-bis(4-isocyanatocyclohexylmethyl)-
cyclohexyl isocyanate should also be useful. These polyisocyanates can be blended or reacted providing
materials applicable to the invention as long as the average functionality remains 2.2 or less and the
product is thermoplastic.

Examples of commercial materials of this type are Upjohn's ISONATE® 143L ("liquid" MDI). Preferably the amount of isocyanates used is the stoichiometric amount based on all the ingredients in the formulation.

Isocyanate-terminated polyurethane prepolymer which should be useful herein may include blocked isocyanate prepolymer. For example, a polyalkylene glycol or polyalkylene ether polyester, polyacetal, polyamide, polyester polyamide or polythioether polyol may be reacted with an excess of a diisocyanate such as those mentioned above to form a suitable prepolymer with residual isocyanate groups.

The prepolymer are formed in a conventional manner and are generally produced by reactions of materials as above and diisocyanates at temperatures of from 10 °C (50 °F) to 54 °C (130 °F), the reaction time being matched to the predetermined temperature, for example, two hours at 49 °C (120 °F).

Certain polyisocyanates useful in the present invention and those not useful in the present invention (due to too high a functionality or resulting in a thermosetting material) are set forth below.

</table>

A further mandatory component, be the same in a preformed polyisocyanate or a polyurethane prepolymer, is a relatively high molecular weight substantially linear polyhydroxyl compound.

Again, the nature of this particular component of the present invention is not particularly limited.

Examples of suitable relatively high molecular weight substantially linear polyhydroxyl compounds with terminal hydroxy groups of the formula HO-D-OH include polyesters, polyester amides, polyesters, polyacets, polyarylates or poly-N-alkylurethanes, other groups such as ester, ether, amide, urethane, or N-alkylurethane groups optionally being present in the above compounds. The molecular weight thereof is more than 500 to 5000, most preferably from 800 to 3000 (number average). The compounds preferably have a melting point below 150 °C, in particular, below 110 °C. It is also possible to use mixtures of these relatively high molecular weight polyhydroxyl compounds.

The following should be particularly useful: polyesters of adipic acid and dialcohols, if desired, mixtures of dialcohols, for example ethylene glycol; propylene glycol; 1,4-butane diol; 2,5-hexane diol; 2,2-dimethyl-1,3-propane diol; 1,6-hexane diol; 2-ethyl-1,6-hexane diol; 2,2-dimethyl-1,3-hexane diol; p-bishydroxymethyl
EP 0 193 346 B1

cyclohexane; 3-methyl-1,4-pentane diol; 2,2-diethyl-1,3-propane diol; more preferably mixtures of these with diols or mixtures of diols containing 5 or more carbon atoms, because polyesters of this kind show a very high resistance to hydrolysis. When the diols contain branched alkyl radicals, the polyesters also show outstanding low temperature elasticity in the end products. Polyesters obtained by polymerizing caprolactones with glycols should also be suitable starting materials.

Other glycols such as hydrogenated bis-phenol A; cyclohexane dimethanol; caprolactone diol (i.e., the reaction product of caprolactone and ethylene glycol); hydroxyalkylated bisphenols; polyether glycols, e.g., poly(oxytetramethylene) glycol and the like should also be useful.

Other useful hydroxy terminated polyols should include polyesters such as polyethylene glycol adipates; polyethylene butylene adipates; the corresponding azelates for these two materials; polycaprolactones; polycarbonates; polyesters; polybutadienes or copolymers with acrylonitrile; styrene; etc.; SH-terminated polyols, etc. Other various types of polyols of higher functionality should also be useful.

These diols or polyols and blends thereof should have utility in this invention if their average functionality is 2.2 or below.

A further mandatory component is a chain extending agent, while these are typically relatively low molecular weight diols, hydroxylamines, amines, dimercaptans, and other conventional chain extending agents should also be useful.

Chain extending agents are compounds which carry, per molecule, at least two active hydrogen atoms and preferably have a molecular weight of from 52 to less than 500, most preferably from 62 to 250 (number average). These compounds react with the isocyanate groups of the prepolymer and build up high molecular weight polyurethane and polyurethane ureas by linking several isocyanate prepolymer molecules.

The following compounds are examples of what we expect to be useful chain extending agents:

ethylene glycol;
propane-1,2-diol;
butane-1,4-diol;
hexane-1,6-diol;
2-(3)-methylenehexane-1,6-diol;
dihydroxythelyurea;
terephthalic acid-bis-(B-hydroxyethylamamide);
hydroquinone-bis-hydroxyethyl ether;
naphthylene-1,5-bis-hydroxyethyl ether;
1:1-dimethyl-4-(bis-B-hydroxyethyl)-semicarbazide;
succinic acid;
adipic acid;
isophthalic acid;
1:4-cyclohexane-dicarboxylic acid;
ethylene diamine;
hexamethylenediamine;
1,4-cyclohexanediamine;
hexahydro-m-xylenediamine;
m-xylenediamine;
p-xylenediamine;
bis(β-aminooethyl)-oxalamide;
piperazine;
2,5-dimethylpiperazine;
ethanolamine;
ω-aminocapric acid;
ω-hydroxybutyric acid;
4,4-diamino-diphenylmethane;
4,4'-diaminodiphenyl-dimethylmethane;
ω-amino-acetic acid hydrazide;
ω-aminobutyric acid hydrazide;
ω-aminocapric acid hydrazide;
ω-hydroxyacetic acid hydrazide;
ω-hydroxybutyric acid hydrazide;
ω-hydroxycapric acid hydrazide;
carbodi hydrazide;
hydracrylic acid dihydrazide;
adipic acid dihydrazide;
isophthalic acid dihydrazide;
m-xyylene-dicarboxylic acid dihydrazide;
ethylene glycol-bis-carbazinic ester;
butanediol-bis-semicarbazide; and
hexamethylene-bis-semicarbazide.

In addition to the bifunctional chain extenders mentioned above, monofunctional additives such as monofunctional amides, amines, alcohols or the like should be useful. Compounds of this type are \( \gamma \)-caprolactam, dibutyl amine and neopentyl alcohol.

While not to be construed as limitative, it is most preferred that the NCO/OH ratio in the reaction system of the present invention be on the order of 0.95 to 1.05; at values substantially in excess of 1.05, the reaction product tends to be non-thermoplastic.

As will be appreciated by one skilled in the art, given the function of the polyol and the diol, the molecular weight of the polyol will generally be greater than that of the diol.

The amount of plasticizer used per the present invention is defined by the range of 0.5 to 7.0 per the following formula:

\[
\frac{A + B + C}{D} = 0.5 \text{ to } 7.0
\]

Where
\[
A = \text{long chain polyol(s)}
\]
\[
B = \text{chain extender(s)}
\]
\[
C = \text{isocyanates(s) or prepolymer(s)}
\]
\[
D = \text{plasticizer(s)}.
\]

Explaining the formula and illustrating the same in more detail:
\[
A = (\text{equivalent weight of long chain polyol(s)}) \times (\text{number of moles thereof})
\]
\[
B = (\text{equivalent weight of chain extender(s)}) \times (\text{number of moles thereof})
\]
\[
C = (\text{equivalent weight of polyisocyanate(s)}) \times (\text{number of moles thereof})
\]
\[
D = \text{plasticizer(s)} (\text{number of grams thereof}).
\]

Example

A is a long chain polyol, equivalent weight is 1000, 1 mole;
B is a short chain diol, equivalent weight is 45, 6 moles used;
C is a polyisocyanate, equivalent weight is 187, 7 moles used; and
1200 grams of plasticizer are used; the above formula would calculate as follows:

\[
\frac{1000 + 270 + 1309}{1200} = 2.15
\]

The result would be 2.15, well within the range defined above.

In most instances, this will mean that the plasticizer will comprise from 15% to 75% total composition weight, more preferably, from 20% to 70% of the total composition weight, and most preferably from 25% to 65% of the total composition weight.

The most important criteria that a plasticizer per the present invention must exhibit is that it must be capable of being reacted into the polyurethane at high temperature, i.e., 165°C (330°F) or more, a temperature substantially higher than is usually encountered for urethane reactions, it must meet the range of 0.5 to 7.0 above and, of course, the resulting product must be a thermoplastic hot melt material, i.e., one that will flow after formation in the comparative low temperature range of (250°F to 450°F) 121°C to 23°C.

It is further necessary that the plasticizer be at most only partially extractable from the final product.

Useful classes of plasticizers should include adipic acid derivatives, azelaic acid derivatives and sebacic acid derivatives such as aliphatic dicarboxylic acid esters, e.g., diisobutyl adipate, heptylnonyl adipate, bis-(2-ethylhexyl) adipate, bis(2-ethylhexyl) azelate and bis(2-ethylhexyl) sebacate (DOS).

Phthalic acid derivatives, most especially phthalate esters, including dialkyl phthalates, diisooalkyl
phthalates singularly or as a mixture, should also be of general application. Examples thereof include dibutyl phthalate, diethyl phthalate, butylcyclohexyl phthalate, heptylnonyl phthalate, heptyloctylcyclohexyldodecyl phthalate (Santicizer 711), dioctyl phthalate (DOP), bis(2-ethylhexyl) phthalate (DOP), (n-hexyl, n-octyl, n-decyl) phthalate (DNODP-810), (n-octyl, n-decyl) phthalate (DNODP-810), isoctyl isodecyl phthalate (DIOAP), diisononyl phthalate, diisodecyl phthalate (DIDP), diundecyl phthalate, didiisodecyl phthalate (DIDP), butylocyclohexyl phthalate, butylbenzyl phthalate, alkylbenzyl phthalate (Santicizer 261), benzyloctyl phthalate (Santicizer 278; 2,2,4-trimethyl-1,3-pentane diol monoobutylated ester), bis(2-butoxyethyl) phthalate (DBOEP), dicyclohexyl phthalate (DCHP) and diphenyl phthalate (DPP).

Glycol derivatives, most especially benzoate esters of glycols or di or other polyglycols should also have general application. Examples thereof include diethylene glycol dipalmitate, triethylene glycol bis(2-ethylhexyl), poly(ethylene glycol)bis(2-ethylhexanoate), methylphthalalylethyl glycolate, butylphthalalylethyl glycolate, tributoxyethyl glycolate, diethylene glycol dibenzoate and glycerol tribenzoate.

Phosphoric acid derivatives, most especially phosphate esters such as triaryl phosphates and alkyl diaryl phosphates should be of general application in the present invention, for example, tributyl phosphate, tris(2-ethylhexyl) phosphate (TOF), tributoxyethyl phosphate, triphenyl phosphate 2/3 with 2-EHDPP (ratios for specific mixtures in this listing are by weight), cresy! diphenyl phosphate, tricresyl phosphate (TCP), isopropylphenyl diphenyl phosphate, t-butyldiphenyl diphenyl phosphate, 2-ethylhexyl diphenyl phosphate (2-EHDPP) -- larger alkyl substituents such as isopropyl and t-butyl groups should also be useful -- isodecyl diphenyl phosphate and chlorinated diphenylphosphates (Phosgard 2XC-20 1/9 with DOP).

Other miscellaneous plasticizers which should be useful in the present invention include isopthalic acid derivatives such as butyl oleate 1/1 with DOP.

If desired, thermoplastic resins can be reacted with the components of the hot melt material of the present invention.

Examples of useful thermoplastic materials include novolac phenolic resins, acrylic resins, epoxy resins, amorphous block copolymers of styrene and butadiene, polyethylene terephthalate, terpene phenolic resins, substituted alkyl phenolic resins, rosin esters, polystyrene, ABS, methyl methacrylates and the like.

Typically these thermoplastic resins are dissolved in the plasticizer(s) and reacted in the system with the plasticizer(s). The maximum used would be at the solubility limit; usually such a resin(s) would be, at most, a maximum of 50 wt.% of the total composition weight.

It is mandatory, per the present invention, that the reaction system used to form the hot melt material be heated to a temperature of at least 165 °C (330 °F). Reaction is usually completed in 2 to 2-1/2 or 3 hours at the reaction temperature of 165 °C (330 °F), most preferably at 173 °C (350 °F) to 221 °C (430 °F). The end point of the reaction can be determined by one or more of a relatively sharp change in the viscosity, the softening point, by testing for free NCO groups, hardness or the color of the product.

We normally determine the end point of the reaction by noting a sharp change in one or more of the recited properties or by testing for the lack of free NCO groups. Thus, the time of reaction may vary from the above range. The minimum temperature is important, however, for plasticizer reaction.

A catalysat may or may not be used per the present invention. If reaction speed or temperature are overriding factors catalysts may be selected to control these factors -- but catalysts are not mandatory per the invention.

Catalysts such as tertiary amines or organic tin compounds or other conventional polyurethane catalysts have been found to be appropriate. The organic tin compound may be a stannous or stannic compound, such as a stannous salt of a carboxylic acid, a trialkyltin oxide, a dialkyltin oxide, a dialkyltin dihalide, a dialkyltin oxide, etc. The organic groups of the organic portion of the tin compound are usually hydrocarbon groups containing from 1 to 8 carbon atoms. For example, dibutyltin dilaurate, dibutyltin diacetate, diethyltin diacetate, dihexyltin oxide, diocytin oxide, stannous octoate, stannous oleate, etc., or a mixture thereof, may be used.

Tertiary amine catalysts include trialkylamines (e.g., trimethylamine, triethylamine), heterocyclic amines, such as N-alkyl morpholines (e.g., N-methylmorpholine, N-ethylmorpholine, etc.), 1,4-dimethylpiperazine, triethylenediamine, etc., and aliphatic polyamines, such as NN,N,N,N'-tetramethyl-1,3-butanediamine. In addition to the aforementioned catalyst, other types of chemicals can function as catalysts for providing special properties and these are included in the term catalyst as they relate to the invention.

Usually we find less than 1 wt.% catalyst base on the total reaction system to be adequate.

Both random copolymers (one shot) and chain extended urethanes (two step) hot melt materials can be obtained per the present invention; preferred procedures for forming the same do slightly differ and, accordingly, the procedures used in the Examples are later defined in detail.

The present invention can be practiced in a batch or continuous fashion, e.g., in a kettle reactor or in a tubular or loop reactor. The Examples illustrate batch operation.
We firstly discuss the preferred procedure for forming a random copolymer urethane hot melt material and then discuss the preferred procedure for forming a chain extended copolymer urethane hot melt material.

For purposes of brevity, in the following discussion regarding forming a random copolymer urethane hot melt material, we merely refer to this as a "random copolymer".

We normally first blend together the long chain linear polyol, the chain extender and the plasticizer and, if used, any additional ingredients such as a thermoplastic resin, filler, etc. Conditions of blending are not important and any conventional blending means can be used, though if it is necessary to melt any material to obtain a solution or to insure a homogeneous system (compatibility), we prefer to accomplish this at the lowest possible temperature to avoid premature reaction until the system is well mixed. For a solid, this would be just slightly above the melting point of the solid or until the solid dissolves in the system and stays dissolved. After dissolution of solids, one can cool the system, if desired, though this is not generally necessary. For a liquid which does not dissolve in the other components, this would be the temperature at which the liquid dissolves and stays dissolved.

Having formed the basic ingredients, the polyisocyanate is then generally added slowly with agitation. There is no special criticality to the conditions used for polyisocyanate addition, but normally we prefer to use the lowest possible temperature to avoid premature reaction until the system is well mixed. Constant agitation is preferred to avoid localized pockets of materials which are not blended into a homogeneous system and, if reaction is occurring, one obviously wishes to avoid "hot spots" in the reaction system.

After a homogeneous mixture results, one then can add the optional catalyst, if desired.

The reaction is then generally permitted to proceed, the exotherm heating the reaction mass.

In line with the above approach, we normally permit the system to exotherm to the maximum temperature (peak exotherm) and then, once the maximum temperature has been reached, we begin to heat the system (any heating system can be used, as desired) to 185-195 °C (365 °F - 390 °F), maintaining constant agitation for 2-1/2 hours to complete the reaction. By permitting the peak exotherm to be reached we thus realize some energy (heat) savings and reduce process cost. This is not necessary for the process, however, and one could just heat after all components are blended.

A typical random copolymer made under the above, conditions resulted in a copolymer showing the following properties:

\[
\text{(c)} \quad \text{Recipe: (a) (b)}
\]

\[
\frac{1}{1200} \quad 6 \quad 7
\]

\[
a = \text{PCP 0240 - Equivalent Weight} \quad = 1000 \times 1 = 1000 \text{ gr.}
\]

\[
b = \text{1-4 Butane Diol - Equivalent Weight} \quad = 45 \times 6 = 270 \text{ gr.}
\]

\[
c = \text{XP 764 - Equivalent Weight} \quad = 187 \times 7 = 1309 \text{ gr.}
\]

\[
d = \text{Benzoflex 958} \quad = 1200 \text{ gr.}
\]

Properties:

Viscosity (350 °F = 5000 cps) 176 °C = 5Nsm⁻²

Softening Point = (250 °F) 121 °C

The procedure with respect to a chain extended urethane hot melt material (in this discussion, chain extended copolymer for brevity) is quite similar to the above, but does differ slightly.

Normally we first blend the long chain linear polyol or the chain extender with the plasticizer and optional resin, etc. Normally only one of the long chain polyol or the chain extender is initially blended. Again, we prefer to use the lowest temperature possible if it is necessary to melt a solid or dissolve a liquid. The polyol or chain extender, whichever is blended first, determines the backbone of the final chain extended copolymer and, as a consequence, the low temperature properties and chemical resistance of the chain extended copolymer and the flexibility (physical) properties of the final chain extended copolymer. The polyisocyanate is then added slowly to either the long chain polyol or the short chain diol (or other chain extender) in a manner to generate a homogeneous system. After the addition of the diisocyanate is
completed, an optional catalyst may be added, and, the batch is permitted to exotherm, e.g., to 93°C (200°F). The earlier discussion with respect to blending conditions regarding random copolymer formation apply with equal force to the chain extended copolymer formation.

Either the long chain polyol or the chain extender, whichever was not initially added, is then added preferably at a temperature lower than the final reaction temperature, whereafter the temperature is elevated to the reaction temperature. While addition at a temperature lower than the final reaction temperature is optional, it avoids loss of low boiling materials open to the atmosphere operation (e.g., chain extender) and seems to provide better molecular weight control and better batch-to-batch reproducibility. For example, we have often used temperatures less than 93°C (200°F) for this addition in combination with good agitation.

The batch is then heated to (365°F - 390°F) 185-199°C for 2-1/2 hours.

A chain extended copolymer made under the above conditions resulted in a copolymer having the following properties:

<table>
<thead>
<tr>
<th>Long Chain Polyol Backbone (A)</th>
<th>Visc.-(2000 cps at 350°F) 2 Ns m⁻² at 177°C</th>
<th>Softening Point (232°F) 111°C</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a)  (b)  (c)</td>
<td>1 - 4 - 7</td>
<td></td>
</tr>
</tbody>
</table>

In the above example the long chain polyol (a) was added first then the isocyanate (c), and after an initial reaction, the chain extender added (b), or

\[ A + C \rightarrow \rightarrow +B \]

<table>
<thead>
<tr>
<th>Short Chain Backbone (B)</th>
<th>Visc.-{(17,200 cps at 350°F) 1.72 Ns m⁻² at 177°C</th>
<th>Softening Point (256°F) 124°C</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a)  (b)  (c)</td>
<td>1 - 4 - 7</td>
<td></td>
</tr>
</tbody>
</table>

In a short chain backbone example as above, the additive sequence was:

\[ B + C \rightarrow \rightarrow +A \]

\[ a = PCP 0240 - Equivalent Weight = 1000 \times 1 = 1000 \text{ gr.} \]
\[ b = 1-4 Butane Diol - Equivalent Weight = 45 \times 6 = 270 \text{ gr.} \]
\[ c = XP 744 - Equivalent Weight = 187 \times 7 = 1309 \text{ gr.} \]
\[ d = Benzoflex 968 = 1200 \text{ gr.} \]

The components of the reaction system of the present invention can obviously be added in any order desired. In the working Examples which are later presented, the polyisocyanate is added last, however.

Obviously additives as are commonly added to polyurethane products such as antioxidants, UV stabilizers, colorants, fillers, etc., can be added to the hot melt material of the present invention in conventional amounts.

The rate of temperature increase from the peak exotherm to the actual reaction temperature (the peak exotherm will normally be substantially less than the reaction temperature) is not important and can be freely selected as desired. Normally we just raise the temperature to the reaction temperature as quickly as is convenient with the heating means used to reduce total processing time.

Having thus described in general the procedure used for the working Examples, the following non-limiting Examples which illustrate what we currently believe to be the best modes of practicing the invention are given.

In the Examples, the following abbreviations or trademark materials are used:

PCP 0200 : polycaprolactone diol; equivalent weight = ca. 500
PCP 0240 : polycaprolactone diol; equivalent weight = ca. 2000
PCP 0260 : polycaprolactone diol; equivalent weight = ca. 3800

The above are long chain linear polyols; number average molecular weight is the equivalent weight...
times the functionality.

T-12: dibutyl tin dilaurate (catalyst)
TMBDA: tetramethylbutanediadimine (catalyst)
Benzoflex 988: diethylene glycol dibenzoate (plasticizer)
XP 744: (a modified liquid methylene diisocyanate adduct of a functionality of 2.0 and an equivalent weight of 187)
K-Flex 500: (a mixture of dipropylene glycol dibenzoate (m.w.:342) and diethylene glycol dibenzoate (m.w.:314); dibenzoate ester assay:98%; plasticizer)
Morflex P51A: (an adipic acid/glycol acetylated polyester; molecular weight: ca. 2,000 (number average); plasticizer)
C-206: (an organophosphene oxide diol, available from FMC)
Polymeg 2000: (polytetramethylene ether glycol; OH number = 57, available from Quaker Chem.)

In the Examples the softening point was determined by the ring and ball method of ASTM E28, all equivalent ratios are given in the order polycaprolactone -1,4-butane diol - diisocyanate (values being in gram moles), with the amount of plasticizer in grams being given thereunder. Thus, e.g., in Example 1, first run, the designation

\[ \frac{1-4-5}{1200} \]

identifies the system PCP 0200 (1 equivalent) -1,4-butane diol (4 equivalents) - XP 744 (5 equivalents) reacted with 1200 g of diethylene glycol dibenzoate, using 20 drops of T-12 or T-12 as a catalyst, reaction being at 185-189°C (365°F-370°F) for 2-1/2 hours after the peak exotherm is reached. The softening point was 107°C (224°F) and the melt viscosity was 0.95Ns.m^{-2} (950 cps) at (350°F) 177°C and melt viscosities were measured at (350°F) 177°C except where otherwise noted and the catalyst is identified as T-12 or TMBDA. In each Example, unless otherwise indicated, 20 drops of catalyst was used, the catalyst being added after completion of diisocyanate addition.

It will be noted in the working examples that at different equivalent ratios not all possible catalyst and long chain diol permutations were used.

For each run which was performed, however, usually the melt viscosity at 177°C (350°F)(unless otherwise noted) is given in Ns.m^{-2} (cps) and the softening point (ASTM E28) in °F. °C are given.

While the Examples show operation under conditions open to the atmosphere, if desired, we believe that operation could be conducted under an inert gas such as nitrogen, argon, neon, etc.

Operation in all of the following Examples was at atmospheric pressure: pressure could be used, we believe, if desired.

In all following Examples, until otherwise indicated, the random copolymer (one shot) formation procedure earlier described was used.

\( \eta_{280(450^\circ F)} \) for viscosity measurement

The above Example shows the effect of the ratio of the diols (based upon equivalent weights) and the type of catalyst used.
Example 2

This example shows the effects obtained where the plasticizer is "post added," i.e., blended into the final random copolymer as opposed to being reacted into the random copolymer as per Example 1. This is illustrated in Runs A, B, and C. The "Control" run corresponds to the second run in Example 1, i.e., the final random copolymer "post added" (Run C). It is also seen that the plasticizer "reacted" into the polymer provides much greater physical and melt properties as compared to the "post added" plasticizer. The procedure used to form the "post added" plasticizer material was to ternell the random copolymer and melt 120 g of the BenzoFlex 988 whereas in Run D a total of 1578 g of BenzoFlex 988 was reacted in as opposed to 1200 g of BenzoFlex 988. Run D was not effective. The polymer is therefore more effective than the "post added" plasticizer.

</table>

This Example was essentially a repeat of Example 1, second run, in Run A with the amount of Benzoflex 988 being doubled (1200 g to 2400 g) in Run B. It is seen that there was little change in melt viscosity and softening point with a doubling of the plasticizer. We believe this is due to the fact that per Example 1 essentially all plasticizer was “reacted” into the random copolymer whereas in Example 3 excess, i.e., that in excess of 1200 g, was not “reacted” into the random copolymer.

Example 4

<table>
<thead>

</tr>
</tbody>
</table>

Example 4 is essentially a rerun of Example 1, second run, except that the plasticizer diethyl phthalate was used instead of Benzoflex 988. The results achieved are seen to be very similar to that of Example 1. Duplicating the above Examples except for changing the plasticizer from diethyl phthalate to K-Flex 500 and Morflex P51A gave the following results:
**Viscosity (400°F)** 204°C **Softening Point**

<table>

**Viscosity** 1.5 Nsm⁻² (1500 · cps)

**Softening Point** 93°C (200°F)

Example 5 is essentially a rerun of Example 1 except that a different diol, i.e., different than a polycaprolactone, was used.

This recipe for the above run using the formula earlier set forth was:

The above run was again duplicated except for varying as below. The viscosity and softening point values obtained are set forth:

Recipe Polymeg 2000 - 984 gr.
1.4-Butane diol - 280 gr.
Benzoflex 988 - 1200 gr.
XP 744 - 1309 gr.
T-12 - 20 drops

Viscosity at 204 °C (400 °F)-(3700 cps) 3.7 Nsm⁻²
Softening Point - (264 °F) 129°C.

This Example establishes that diols other than polycaprolactones can be used with success in the present invention.
Example 6

PCP 0240 1000 g
1,4-butane diol 270 g
Benzoflex 988 1200 g
XP 744 1309 g

Catalyst: None

Viscosity: 15 N\(\text{m}^{-2}\) (15,000 cps)
Softening Point: 128°C (262°F)

This is essentially a rerun of Example 1 except no catalyst was used. The only variation was that the PCP 0240 was melted with the Benzoflex 988 and the 1,4-butane diol, the XP 744 was added and the system was heated at 185°C (365°F) for 2 hours. While no catalyst was used in the above run, heat was applied. The above run was duplicated except varying as follows: 20 drops of TMDBA was added following polyisocyanate addition; and rather than heating, all ingredients were merely placed into a container after mixing and stirred until the reaction exotherm ceased. The container was then retained for two weeks at room temperature and then the resulting random copolymer was removed.

Surprisingly, the random copolymer had no desirable properties in the sense of the present invention until it was heated to 185°C (330°F) for a period of 15 minutes. For example, heating at 138°C (280°F) for 15 minutes did not provide a desired hot melt composition, rather, the same resembled “cottage cheese”.

The exact time of heating is not important in this embodiment, rather, what is important is to elevate to at least 185°C (330°F). It must be noted that curing has proceeded for two weeks.

Following the above treatment, the following physical properties were determined:

- Viscosity at (400°F - 5300 cps) 204°C - 5.3N\(\text{m}^{-2}\)
- Softening point - (278°F) 137°C

The above runs demonstrate that hot melt materials per the present invention cannot be formed without the use of heat as defined above at some point prior to or during use.

It should be noted that if the polymer is made without heat (no additional heat is supplied other than the system being permitted to exotherm), a soft unusable product in the sense of the present invention is obtained. In distinction, if the polymer is heated after the reaction is complete at a later time and applied as a hot melt, the typical desirable physical properties of the present invention are obtained.

There are a number of additional ingredients which are also optional in the sense of the present invention. These are briefly discussed below.

Conventional fillers for use herein include, for example, aluminum silicate, calcium silicate, magnesium silicate, calcium carbonate, barium sulfate, calcium sulfate, glass fibers, carbon black and silica. The filler, if used, is normally present in an amount ranging from 5 to 50% by weight of final resin solids.

The above listing of fillers is not, of course, in any fashion limiting.

The main purposes of using a filler would be as a reinforcing agent, to influence rheological properties, and to lower cost. It is further preferred that the fillers be free from water.

If desired, the hot melt material of the present invention can be foamed. Many alternatives will be apparent to one skilled in the art. For example, a gaseous material such as nitrogen, etc., can be introduced into the liquid hot melt while the same is under pressure and, when the pressure is removed, the gaseous material will result in a foamed hot melt material. As an alternative, a material which decomposes at the temperature of use could be added to the hot melt material after production.

Claims
1. A process for forming, a hot melt composi-\textsuperscript{tio} comprising a polyurethane having at least one plasticiser reacted therein formed from at least one isocyanate having a functionality less than 2.2 at least one long chain polyl having a number average molecular weight of more than 500 to 5000 and an average functionality of 2.2 or below or at least one chain extender and at least one plasticiser characterised by heating a mixture of the above-named components at a temperature of at least 165 °C, wherein said components are present in an amount to meet the following formula:

\[
\frac{A + B + C}{D} = 0.5 \text{ to } 7.0
\]

wherein:
- A represents the equivalent weight of the long chain polyl x the number of moles thereof used;
- B represents the equivalent weight of the chain extender x the number of moles thereof used;
- C represents the equivalent weight of the isocyanate x the number of moles thereof used; and
- D represents the number of grams of plasticiser.

2. A process according to claim 1, wherein the mixture is maintained at a temperature of at least 163 °C for at least 2 hours.

3. A process according to claim 1 or 2, wherein heating is for 2 to 3 hours at a temperature of from 176 °C to 221 °C.

4. A process according to claim 1, wherein said composition is substantially completely cured in situ and then said heating is for at least 3 minutes.

5. A process according to any preceding claim, such that the thermoplastic hot melt composition formed exhibits a viscosity of less than 50 Ns.m\textsuperscript{-1} at a temperature of 121 °C to about 232 °C.

6. A process according to any preceding claim, wherein said isocyanate has a functionality of 2.15 or less.

7. A process according to any preceding claim, wherein said isocyanate contains two isocyanate groups and from 6 to 100 carbon atoms.

8. A process according to any preceding claim, wherein said chain extending agent as a number average molecular weight of from 52 to less than 500.

9. A process according to any preceding claim, wherein the NCO/OH ratio 0.95 to 1.05.

Reverifications

1. Procédé de préparation d'une composition thermofusible comprenant un polyuréthane dans lequel a réagi au moins un plastifiant formé d'au moins un isocyanate ayant une fonctionnalité inférieure à 2,2, au moins un polyl à longue chaîne ayant un nombre moyen de poids moléculaire supérieur d'au moins 500 à 5000 et une fonctionnalité de 2,2 ou moins, au moins un allongeur de chaîne et au moins un plastifiant, caractérisé en ce qu'on chauffe à mélanges les composants désignés ci-dessus à une température d'au moins 165 °C, dans lequel lesdits composants sont présents dans une quantité qui satisfait à la formule suivante :

\[
\frac{A + B + C}{D} = 0,5 \text{ à } 7,0
\]

où :
- A représente le poids équivalent du polyl à longue chaîne multiplié par le nombre de moles utilisées dudit polyl à longue chaîne;
- B représente le poids équivalent de l'allongeur de chaîne multiplié par le nombre de moles utilisées...
utilisées dudit allongeur de chaîne;
C représente le poids équivalent de l’isocyanate multiplié par le nombre de moles utilisées dudit isocyanate; et
D représente le nombre de grammes de plastifiant.

2. Procédé selon la revendication 1, dans lequel le mélange est maintenu à une température d’au moins 165 °C pendant au moins 2 heures.

3. Procédé selon la revendication 1 ou la revendication 2, dans lequel le chauffage dure de 2 à 3 heures à une température de 176 °C à 221 °C.

4. Procédé selon la revendication 1, dans lequel ladite composition est sensiblement complètement cuite in situ, et ensuite ledit chauffage dure au moins 3 minutes.

5. Procédé selon l’une quelconque des revendications précédentes, tel que la composition thermoplastique polymère forme présente une viscosité inférieure à 50 Nsm⁻² à une température de 121 °C jusqu’environ 232 °C.

6. Procédé selon l’une quelconque des revendications précédentes, dans lequel ledit isocyanate a une fonctionnalité de 2,15 ou moins.

7. Procédé selon l’une quelconque des revendications précédentes, dans lequel ledit isocyanate contient deux groupes isocyanate et de 6 à 100 atomes de carbone.

8. Procédé selon l’une quelconque des revendications précédentes, dans lequel ledit agent allongeur de chaîne a un nombre moyen de poids moléculaire allant de 52 à moins de 500.

9. Procédé selon l’une quelconque des revendications précédentes, dans lequel le rapport NCO/OH est compris entre 0,95 et 1,05.

Patentansprüche

1. Verfahren zur Herstellung einer Heißschmelzmasse, umfassend ein Polyurethan mit wenigstens einem darin umgesetzten Weichmacher, der aus wenigstens einem Isocyanat mit einer Funktionalität von weniger als 2,2, wenigstens einem langkettigen Polyl mit einem Zahlenmittel des Molekulargewichts von mehr als 500-5000 und einer mittleren Funktionalität von 2,2 oder weniger, wenigstens einem Kettenverlängerer und wenigstens einem Weichmacher gebildet ist, gekennzeichnet durch Erwärmen einer Mischung der obengenannten Komponenten auf eine Temperatur von wenigstens 165 °C, wobei die Komponenten in einer Menge vorhanden sind, die der folgenden Gleichung genügt:

\[
\frac{A + B + C}{D} = 0.5 \text{ to } 7.0
\]

wobei:
- A = das Äquivalentgewicht des verwendeten langkettigen Polyols x dessen Molzahl;
- B = das Äquivalentgewicht des verwendeten Kettenverlängerers x dessen Molzahl;
- C = das Äquivalentgewicht des verwendeten Isocyanats x dessen Molzahl; und
- D = die Anzahl Gramm des Weichmachers.

2. Verfahren nach Anspruch 1, wobei die Mischung für wenigstens 2 h auf einer Temperatur von wenigstens 165 °C gehalten wird.

3. Verfahren nach Anspruch 1 oder 2, wobei die Erwärmung für 2-3 h bei einer Temperatur von 176-221 °C erfolgt.

4. Verfahren nach Anspruch 1, wobei die Masse im wesentlichen vollständig in situ ausgehärtet wird und dann die Erwärmung für wenigstens 3 min erfolgt.
5. Verfahren nach einem der vorhergehenden Ansprüche derart, daß die hergestellte thermoplastische Heißschmelzmasse bei einer Temperatur von 121 °C bis ca. 232 °C eine Viskosität von weniger als 50 Ns/m² hat.

6. Verfahren nach einem der vorhergehenden Ansprüche, wobei das Isocyanat eine Funktionalität von 2,15 oder weniger hat.

7. Verfahren nach einem der vorhergehenden Ansprüche, wobei das Isocyanat zwei Isocyanatgruppen und 6-100 Kohlenstoffatome enthält.

9. Verfahren nach einem der vorhergehenden Ansprüche, wobei das NCO/OH-Verhältnis 0,85-1,05 ist.
