Styryl pyrazoles, isoxazoles and analogs thereof having activity as 5-lipoxygenase inhibitors and pharmaceutical compositions containing them.
Description

This is a continuation in part of United States Serial No. 910,692 filed September 22, 1988, which is a continuation in part of United States Serial No. 861,179 filed May 9, 1986.

The present invention is a novel styryl pyrazoles and analogs thereof as well as pharmaceutical compositions containing them.

Styryl isozazole derivatives having cardiovascular activity are known. For example, European Patent Applications No. 34754 and NO. 5192 and German Application No. 2943-405 having Derwent Abstract Nos. 63618 D/37, 84501 B/47 and 34567 D/20, respectively, disclose a compound of the general formula

![Chemical Structure](image)

However, the present compounds differ from such references by a completely different side chain from that shown above linked to the phenyl at the 2-position through an ether group in each reference. Further, European Patent Application No. 5166 reviewed by Derwent Abstract No. 844908/47 discloses an intermediate isozazole of the formula

![Chemical Structure](image)

for which no pharmaceutical utility is disclosed.

Pyrazole derivatives having biological, specifically antiinflammatory, activity are found in Belgian Patent Nos. 819,890 and 844,972 abstracted in Derwent Abstract Nos. 20948W/13 and 08406Y/06, respectively. A similar derivative is disclosed in German Patent No. 292041 of Derwent Abstract No. 86535C/49. However, each of these disclosed pyrazole derivatives requires substituents on adjacent carbons of the pyrazole ring.

Specifically excluded from the compounds of the present invention are the compounds of French Patent No. 2104336 of Derwent Abstract No. 46150T-B useful as hypcholesteroleemics, antiinflammatories, analgesics, sedatives, antipyretics, and in some instances diuretics. The compounds of the French Patent generally have the formula

![Chemical Structure](image)

Finally, of lesser interest numerous imidazoles are known having various pharmaceutical activity. For
example, U.S. Patent No. 3812111 and British 1,046,248 disclose compounds of general formula

\[
\begin{align*}
\text{phenyl, isopropyl, or} & \quad \text{hydroxyethyl} \\
\end{align*}
\]

respectively wherein the - represents various substituents. However, the imidazoles are compounds differing from the present invention in that the compounds have a different ring system from the pyrazoles.

Thus, the novel compounds that are the present invention provide activity for use in the treatment of diseases in which 5-lipoxygenase enzyme activity contributes to the pathological condition. For example, the use for the present novel compounds, compositions and methods of use is for allergy, asthma, arthritis, skin disorders, such as psoriasis or acne, inflammation, for example, inflammatory bowel disease or pain, and further, also cardiovascular disorders including infarction, angina, arrhythmias, stroke, migraine, atherosclerosis, ulcers and other conditions particularly benefited by cytoprotective activity. An additional property of the present novel compounds now found to provide usefulness, for example, as sun screens, is absorption of ultraviolet light.

The present invention is a novel compound of the formula (I)

The compounds of the present invention contemplate compounds having the following ring systems
wherein ..., R₅ and Z are as defined above.
When R₅ is hydrogen it is understood the ring system may be represented by the following equilibrium:
The compounds of formula I are useful both in the free base form, in the form of base salts where possible, and in the form of acid addition salts. The three forms are within the scope of the invention. In practice, use of the salt form amounts to use of the base form. Appropriate pharmaceutically acceptable salts within the scope of the invention are those derived from mineral acids such as hydrochloric acid and sulfuric acid; and organic acids such as methanesulfonic acid, benzenesulfonic acid, p-toluenesulfonic acid, and the like, giving the hydrochloride, sulfamate, methanesulfonate, benzenesulfonate, p-toluenesulfonate, and the like, respectively or those derived from bases such as suitable organic and inorganic bases. Examples of suitable inorganic bases for the formation of salts of compounds of this invention include the hydroxides, carbonates, and bicarbonates of ammonia, sodium, lithium, potassium, calcium, magnesium, aluminum, zinc, and the like.

Salts may also be formed with suitable organic bases. Bases suitable for the formation of pharmaceutically acceptable base addition salts with compounds of the present invention include organic bases which are nontoxic and strong enough to form such salts. These organic bases form a class whose limits are readily understood by those skilled in the art. Merely for purposes of illustration, the class may be said to include mono-, di-, and trialkylamines, such as methyamine, dimethylamine, and triethylamine; mono-, di-, or trihydroxyalkylamines such as mono- or di- or triethanolamine; amino acids such as arginine, and lysine; guanidine; N-methylglucosamine; N-methyglucamime; L-glutamine; N-methylpiperazine; morpholine; ethylenediamine; N-benzylphenethyamine; tris(hydroxymethyl)aminomethane; and the like. (See for example, "Pharmaceutical Salts," J. Pharm. Sci. 66 (1):1-19 (1977.))

The acid addition salts of said basic compounds are prepared either by dissolving the free base of compound I, I' or II in aqueous or aqueous alcohol solution or other suitable solvents containing the appropriate acid or base and isolating the salt by evaporating the solution, or by reacting the free base of compound I, I' or II with an acid as well as reacting compound I, I' or II having an acid group thereon with a base such that the reactions are in an organic solvent, in which case the salt separates directly or can be obtained by concentration of the solution.

The compounds of the invention may contain an asymmetric carbon atom. Thus, the invention includes the individual stereoisomers, and the mixtures thereof. The individual isomers may be prepared or isolated by methods known in the art.

Compounds of the present invention that are preferred are of formula I wherein Y is N and X is NH or Y is N and X is O.

The most preferred compounds of the present invention are 5-[β-(4′-hydroxy-3′,5′-bis(1,1-dimethylethyl)-phenyl)ethenyl]-3-methylisoxazole, 3-[β-(4′-hydroxy-3-methoxyphenyl)ethenyl]-5-methylpyrazole, and 5-[β-(4′-hydroxy-3′,5′-dimethoxyphenyl)ethenyl]-3-methylisoxazole.

A physician or veterinarian of ordinary skill readily determines a subject who is exhibiting symptoms of any one or more of the diseases described above. Regardless of the route of administration selected, the compounds of the present invention of the formula I as described in pharmaceutical compositions above are formulated into pharmaceutically acceptable dosage forms by conventional methods known to the pharmaceutical art.

The compounds can be administered in such oral unit dosage forms as tablets, capsules, pills, powders, or granules. They also may be administered rectally or vaginally in such forms as suppositories or bougies; they may also be introduced parenterally (e.g., subcutaneously, intravenously, or intramuscularly), using forms known to the pharmaceutical art. They are also introduced directly to an affected area (e.g., in the form of eye drops or by inhalation). For the treatment of asthma or allergies, particularly dermatological disorders; such as erythema, psoriasis and acne, the compounds may also be administered topically in the form of ointments, gels, or the like. However, in general, the preferred route of administration is orally.

An effective but nontoxic quantity of the compound is employed in treatment. The ordinarily skilled physician or veterinarian will readily determine and prescribe the effective amount of the compound to prevent or arrest the progress of the condition for which treatment is administered. In so proceeding, the physician or veterinarian could employ relatively low dosages at first, subsequently increasing the dose until a maximum response is obtained.

Initial dosages of the compounds of formula I of the invention in pharmaceutical compositions are ordinarily in the area of 10 mg up to 2 grams per day orally, preferably 10 mg to 500 mg per dose orally given one to four times daily or as needed. When other forms of administration are employed equivalent doses are administered.

Additionally, the present invention is compositions comprising the compounds of formula I, for use as sunscreens, having a suitable carrier therefor.

The ultraviolet absorbing properties of the compounds of the present invention is generally shown by a comparison with p-aminobenzoic acid which is the active ingredient in most commercial sunscreens. Such
properties are within the ultraviolet absorbing ranges of 280 to 300 nM range critical to effectiveness. A representative compound of the invention is compared to p-aminobenzoic acid in the following Table.

The methods of preparation for the compounds of the present invention may, generally, be accomplished in a manner according to the definition of \( X \) and \( Y \).

For example, generally compounds of formula I wherein \( X \) and \( Y \) are each \( =\text{N-} \) or \( \text{NRs} \) are prepared in a manner shown by Scheme I as follows:
wherein \( \cdots \), \( R, R_1, R_2, R_5 \) and \( Z \) are as defined above.

In Step 1 of Scheme I equimolar parts of hydrazine hydrate and a compound of the formula I/I are combined in a solvent such as 1 part ethanol and 1 part butanol, or 2-propanol, and the like. A small amount of about 0.1 ml to 10 ml preferably 0.5 ml of acetic acid is added with the hydrazine hydrate. Optionally, the step 1 product of formula I is further reacted as shown in step II with a compound MR wherein M is an electrofuge such as halogen, sulfonate, or the like and \( R_5 \) is as defined above but other than hydrogen to obtain a mixture of the compound of formula I and I', wherein \( \cdots \), \( R, R_1, R_2, R_5 \) when not hydrogen and 2 are as defined above. The compounds I and I' may be separated by conventional means.
Similarly compounds of formula I wherein X and Y are each N or NR₅ wherein Q is CH₂ and n is 1 can be prepared according to the following Scheme Ia using analogous conditions as provided above for Scheme I.

**SCHEME Ia**

Further, the compounds of formula Iₜ are prepared as shown in the following Scheme II and IIa.
wherein X and Y are O or N and S or N.
Triphenylphosphonium halide; preferably chloride, of the formula II₂ or II₂ₐ are contacted by an excess of a compound of the formula III₂ or III₂ₐ in a solvent such as dimethylsulfoxide, toluene, or the like to which an equivalent amount of potassium t-butoxide is added. The mixture is stirred at about room temperature for from 10 minutes to 2 hours or more under an inert atmosphere. A compound of formula I₂ or I₂ₐ is obtained wherein R, R₁, R₂ and Z are as defined above and Y and X are each either N or O and N or S, respectively.

Mild hydrogenation by conventional methods by an ordinarily skilled artisan may be carried out to provide a compound of formula I₂ wherein R, R₁, R₂ and Z are as defined and Y and X are O or N and S or N, respectively.

Additionally, for compounds wherein Z is defined such that the two substituents on the heterocyclic ring of formula

are the same, the compounds may be prepared according to the following Scheme III.
wherein $Z$ is

and wherein $R$, $R_1$, $R_2$, and $Q$ are as defined above and $Y$ and $X$ are either O and N or N and O.

The conditions of the reaction in Scheme III are, generally, carried out with equimolar parts of the compound of formula III' and hydroxylamine hydrochloride in a solvent such as methanol, ethanol and the like in the presence of a buffer such as sodium acetate at reflux temperature until completion as determined by TLC.
**Scheme IV**

wherein \( R, R_1, R_2, \) and \( Z \) are as defined above.

The conditions of the synthesis in Scheme IV step 1 are, generally, carried out in a manner analogous to those described by C. Kashima et al, Bull. Chem. Soc. Japan, 46, 310 (1973) and C. Kashima et al, Heterocycles, 6, 805 (1977). Unexpectedly the step 2 dehydration when \( R_4 \) is H or alkyl and also further decarboxylation when \( R_4 \) is H are carried out in a one pot reaction together with step 1. Conditions for step 2 are analogous to those known in the art and, thus, within the ordinary artisan's skill.

Finally, conditions analogous to those described in copending application PD-3493 United States Serial Number 851,003, filed April 11, 1986 are useful in step 1 of Scheme VI below. Step 2 of Scheme VI is carried out using anhydrous conditions in an inert solvent at about the temperature of 0°C to 50°C for from 90 min to 18 hours.

The compounds in Scheme VII are compounds wherein R, R₁, R₂ and Z are as defined above for compounds of formula III₅ and III₆ but III₁ and III₁ are symmetrical.

An alternate preparation for the compounds of formula III₅ is as found in Scheme VIII as follows:
Finally, the compound of formula I₂ as shown in Scheme II above can be prepared by the following method.
SCHEME IX

Examples of suitable oxygen protecting groups are benzyl, t-butyldimethylsilyl, ethoxyethyl, and the like. Protection of an N-H containing moiety is necessary for some of the processes described herein for the preparation of compounds of this invention. Suitable nitrogen protecting groups are benzyl, triphenylmethyl, trialkylsilyl, trichloroethylcarbamate, trichloroethoxy carbonyl, vinylloxy carbamate, and the like.

Under certain circumstances it is necessary to protect two different oxygens with dissimilar protecting groups such that one can be selectively removed while leaving the other in place. The benzyl and t-butyldimethylsilyl groups are used in this way; either is removable in the presence of the other, benzyl being removed by catalytic hydrogenolysis, and t-butyldimethylsilyl being removed by reaction with, for example, tetra-n-buty lammonium fluoride.

In the process described herein for the preparation of compounds of this invention the requirements for protective groups are generally well recognized by one skilled in the art of organic chemistry, and accordingly the use of appropriate protecting groups is necessarily implied by the processes of the chart herein, although not expressly illustrated.

The products of the reactions described herein are isolated by conventional means such as extraction, distillation, chromatography, and the like.

Starting materials not described herein are available commercially, are known, or can be prepared by methods known in the art.

The salts of the compounds of formula I described above are prepared by reacting the appropriate base or acid with a stoichiometric equivalent of the compounds of formula I, respectively, to obtain pharmaceutically acceptable salts thereof.

The usefulness of the compounds of the present invention as inhibitors of lipoygenase enzyme or other related biochemical actions is demonstrated by their effectiveness in various standard test procedures. A description of each procedure follows.

5-Lipoygenase Assay Using Isolated Human Leukocytes (5LOA₂)

The formation of 5-HETE in human leukocytes is considered a measure of 5-lipoygenase activity. The protocol is described in the following.

Fresh heparinized or EDTA treated human blood is mixed with 6% dextran-3% dextrose in isotonic saline in the ratio 0.25 ml dextran solution per 1.0 ml blood. After mixing the blood is allowed to sit at room temperature for about 90 minutes while the RBC's settle. During this period, the plasma is removed with a plastic pipette to nalgens tubes.

The plasma is centrifuged at 800 rpm (125 kg) on the Beckman Td-b refrigerated centrifuge to remove the platelets (which remain in the supernatant). The pellet, consisting of leukocytes and erythrocytes, is treated with 10 ml 0.87% ammonium chloride at room temperature for four minutes, lysing the red cells. At the end of four minutes the cells are diluted with a 2x volume of phosphate buffered saline, pH 7.4, and centrifuged for ten minutes. The cells are washed three times with the phosphate buffered saline. Any of the pelleted cell matter which is not easily resuspended is discarded during the washings—the material contains platelets (12-lipoygenase activity).

After washing, the cells are resuspended in phosphate buffered saline containing 1.0 mM calcium and 0.5 mM magnesium. After counting, the cells are diluted to 1.5-2.0 × 10⁷ leukocytes per milliliter.

To each polypropylene reaction tube is added 0.48 ml leukocytes in Ca-Mg phosphate buffered saline, pH 7.4; 1-5 μl test compound dissolved in DMSO and buffer; or DMSO for control tubes.

The tubes preincubate at 37 °C for five minutes.

The reaction is started by adding 20 μl of the following: 0.5 μl, 20 mM arachidonic acid—final concentration = 20 μM; 1 μl, 5 mM calcium ionophore A23187—final concentration = 10 μM; and 18.5 μl buffer.

The reaction proceeds for five minutes, then is stopped by adding 0.5 ml, 0.5 mM ice-cold Tris buffer, pH 8.0. The tubes are chilled on ice for ten minutes and then extracted three times with a total of 3.5 ml ethyl acetate (3.0 ml removed).

The tubes can be stored at this point. For extended storage, the tubes should be filled with nitrogen.

The ethyl acetate is evaporated with a Sorvall Speed-Vac. The residue is dissolved in ethanol. The
tubes can also be stored at this point at -20 °C under nitrogen.

A portion of the ethanol solution is injected into the HPLC system for 5-HETE quantitation.

The HPLC system consists of Hewlett-Packard 1040A UV spectrophotometry system with an HP86 computer. Injections are made automatically with a Waters WISP 710B. The pump is a Spectra Physics SP8700. Peaks are measured with a Hewlett-Packard 3390A integrator. An RP C-18 column is used. The solvent system is isocratic; the solvent is 70% methanol and 30% 0.01M sodium acetate, pH 5.7, pumped at 1.0 ml/min. The flow is monitored at 235 nm for 5-HETE quantitation. Using a 15 cm Alltech Nucleosil C-18 5 μM column provides for a sample turnaround time of about 16 minutes.

IC \textsubscript{50} is calculated as the amount of test agent that causes 50% inhibition of the formation of 5-HETE relative to the control.

Cyclooxygenase Enzyme Assay

Additionally, inhibition of cyclooxygenase is considered a measure of relevance to the pathophysiology of the above noted diseases. For example, see "Inhibition of Immunoglobulin E-Mediated, Antigen-Induced Monkey Asthma and Skin Reactions by \textit{5,8,11,14-Eicosatetraynoic Acid}," by Roy Patterson, M.D. and Kathleen E. Harris, B.S. in, J. Allergy Clin. Immunol., Vol. 67, No. 2, pp. 146-152.

The assay consists of incubating 2 mg bovine seminal vesicle powder with 2 mM epinephrine, 2.5 mM reduced glutathione, 100 μM arachidonic acid, and the test agent for 20 minutes. The reaction mixture is acidified and extracted with ethyl acetate (3 x 1.0 ml) and the pooled extract is evaporated to dryness using a Speed Vac Concentrator or under a stream of nitrogen. The residue is dissolved in ethanol. An aliquot is applied on 20 x 20 cm silica gel plate and developed using water:ethyl acetate:hexane:acetic acid (60:54:25:12.5, upper phase) to separate PGE\textsubscript{2} from arachidonic acid. \textsuperscript{14}C-PGE\textsubscript{2} formed is identified by co-chromatography with authentic \textsuperscript{3}H-PGE\textsubscript{2} and the amount of radioactivity is quantitated using an automatic TLC linear scanner (Berthold, Pittsburgh, Pennsylvania) linked to an Apple II-e computer and an IC \textsubscript{50} is calculated as the amount of test compound causing 50% inhibition of cyclooxygenase enzyme relative to the control.

The above defined value for each of tested compounds of the present invention having the noted Example numbers are as found in the following Table 2.

ARBL/ARBC Whole Cell 5-Lipoxigenase and Cyclooxygenase Assays

Materials

The rat basophilic leukemia cell line (RBL-1) was obtained from the American Type Culture Collection (Rockville, MD).

Radioimmuno assay (RIA) kits of LTB₄ and PGF₂α were obtained from Amersham (Arlington Heights, IL) and Seragen (Boston, MA) respectively.

All tissue culture media were obtained from GIBCO (Grand Island, NY).

Method

RBL-1 cells were grown in culture (suspension) in Eagle's minimum essential medium supplemented with 12% fetal bovine serum and 1:100 antibiotic-antimycotic mixture at 37° C in an incubator supplied with air-5% carbon dioxide. Cells were harvested by centrifugation. They were washed with cold phosphate buffered saline pH 7.4 (PBS; NaCl, 7.1 g; Na₂HPO₄, 1.15 g; KH₂PO₄, 0.2 g; and KCl, 0.2 g/L). Cells were finally suspended in PBS containing 0.88 μM calcium at a density of 2.4×10⁶ cells/ml. Cells were incubated with and without test agent (in DMSO) (1% DMSO was without effect on arachidonic acid metabolism) for ten minutes at room temperature. Calcium ionophore A23187 (5 μM) was added and cells were incubated for seven minutes at 37° C. The reaction was stopped by chilling the tubes in ice for ten minutes. Cells were separated by centrifugation and the supernatant was stored at -20°. Aliquots (100 μl) were analyzed for LTB₄ and PGF₂α using radioimmuno assay kits as provided by the supplier.

Table 3 contains biochemical data obtained from this RBL-1 whole cell assay.

<sup>a</sup>ARBL-1 intact cell 5-lipoxygenase IC<sub>50</sub> values (μM)

<sup>b</sup>ARBL-1 intact cell cyclooxygenase IC<sub>50</sub> values (μM)

Accordingly, the present invention also includes a pharmaceutical composition for treating one of the above diseases or conditions comprising an anti-inflammatory or anticondition effective amount of a compound of the formula I as defined above together with a pharmaceutically acceptable carrier.

The present invention further includes a method of use of a compound of the formula I for the manufacturing of pharmaceutical compositions for the treatment of the above named diseases.

For preparing pharmaceutical compositions from the compounds described by this invention, inert, pharmaceutically acceptable carriers can be either solid or liquid. Solid form preparations include powders, tablets, dispersible granules, capsules, cachets, and suppositories. A solid carrier can be one or more substances which may also act as diluents, flavoring agents, solubilizers, lubricants, suspending agents, binders or tablet disintegrating agents; it can also be encapsulating material. In powders, the carrier is a finely divided solid which is in admixture with the finely divided active compound. In the tablet the active compound is mixed with carrier having the necessary binding properties in suitable proportions and compacted in the shape and size desired. The powders and tablets preferably contain from 5 or 10 to about 70 percent of the active ingredient. Suitable solid carriers are magnesium carbonate, magnesium stearate, talc, sugar, lactose, pectin, dextrin, starch, gelatin, tragacanth, methylcellulose, sodium carboxymethylcellulose, a low melting wax, cocoa butter, and the like. The term "preparation" is intended to include the formulation of the active compound with encapsulating material as carrier providing a capsule in which the active component (with or without other carriers) is surrounded by carrier, which is thus in association with it. Similarly, cachets are included. Tablets, powders, cachets, and capsules can be used as solid dosage forms suitable for oral administration.

For preparing suppositories, a low melting wax such as a mixture of fatty acid glycerides or cocoa
butter is first melted, and the active ingredient is dispersed homogeneously therein as by stirring. The molten homogeneous mixture is then poured into convenient sized molds, allowed to cool and thereby to solidify.

Liquid form preparations include solutions, suspensions, and emulsions. As an example may be mentioned water or water-propylene glycol solutions for parenteral injection. Liquid preparations can also be formulated in solution in aqueous polyethylene glycol solution. Aqueous solutions suitable for oral use can be prepared by dissolving the active component in water and adding suitable colorants, flavors, stabilizing and thickening agents as desired. Aqueous suspensions suitable for oral use can be made by dispersing the finely divided active component in water with viscous material, i.e., natural or synthetic gums, resins, methylcellulose, sodium carboxymethylcellulose, and other well-known suspending agents.

Also included are solid form preparations which are intended to be converted, shortly before use, to liquid form preparations for either oral or parenteral administration. Such liquid forms include solutions, suspensions, and emulsions. These particular solid form preparations are most conveniently provided in unit dose form and as such are used to provide a single liquid dosage unit. Alternately, sufficient solid may be provided so that conversion to liquid form, multiple individual liquid doses may be obtained by measuring predetermined volumes of the liquid form preparation as with a syringe, teaspoon, or other volumetric container. When multiple liquid doses are so prepared, it is preferred to maintain the unused portion of said liquid doses at low temperature (i.e., under refrigeration) in order to retard possible decomposition. The solid form preparations intended to be converted to liquid form may contain, in addition to the active material, flavorants, colorants, stabilizers, buffers, artificial and natural sweeteners, dispersants, thickeners, solubilizing agents, and the like. The liquid utilized for preparing the liquid form preparation may be water, isotonic water, ethanol, glycerine, propylene glycol, and the like as well as mixtures thereof. Naturally, the liquid utilized will be chosen with regard to the route of administration, for example, liquid preparations containing large amounts of ethanol are not suitable for parenteral use.

Preferably, the pharmaceutical preparation is in unit dosage form. In such form, the preparation is subdivided into unit doses containing appropriate quantities of the active component. The unit dosage form can be a packaged preparation, the package containing discrete quantities of preparation, for example, packeted tablets, capsules, and powders in vials or ampoules. The unit dosage form can also be a capsule, cachet, or tablet itself or it can be the appropriate number of any of these in packaged form.

The quantity of active compound in a unit dose of preparation may be varied or adjusted from 1 mg to 500 mg preferably to 1 to 50 mg according to the particular application and the potency of the active ingredient. The composition can, if desired, also contain other compatible therapeutic agents.

In therapeutic use as described above, the dosages may be varied depending upon the requirements of the patient, the severity of the condition being treated, and the compound being employed. Determination of the proper dosage for a particular situation is within the skill of the art. Generally, treatment is initiated with the smaller dosages which are less than the optimum dose of the compound. Thereafter the dosage is increased by small increments until the optimum effect under the circumstances is reached. For convenience, the total daily dosage may be divided and administered in portions during the day if desired.

As used herein cardiovascular diseases or conditions particularly include 1) reductions of the extent of infarct damage in a myocardial infarction, 2) prevention of recurrent myocardial infarction, 3) stroke, 4) anaphylactic shock, and 5) vasospastic disease.

An additional advantageous benefit of the cytoprotective property of the compounds of formula I are for use, for example to protect against damage from various gastro-intestinal tract conditions.

Various assays that are generally accepted can be used to measure cytoprotective ability.

The magnitude of a prophylactic or therapeutic dose of a compound of formula I will, of course, vary with the nature of the severity of the condition to be treated and with the particular compound of formula I and its route of administration. In general, the daily dose range for anti-asthmatic, anti-allergic or anti-inflammatory use and, generally uses other than cytoprotection, lies within the range of from about 10 μg to about 20 mg per kg body weight of a mammal, preferably from about 50 μg to about 20 mg per kg of body weight of a mammal, and most preferably from about 100 μg to about 10 mg per kg of body weight of a mammal.

The exact amount of a compound of the formula I to be used as a cytoprotective agent will depend on, inter alia, whether it is being administered to heal damaged cells or to avoid future damage, on the nature of the damaged cells (e.g., gastro-intestinal ulcers vs. nephrotic necrosis), and on the nature of the causative agent. An example of the use of a compound of the formula I in avoiding future damage would be co-administration of a compound of the formula I with a non-steroidal anti-inflammatory drug (for example, indomethacin) that might otherwise cause such damage. For such use, the compound of formula I is administered from 30 minutes prior up to 30 minutes after administration of the NSAID. Preferably, it is
administered prior to or simultaneously with the NSAID (e.g., as a combination dosage form).

The effective daily dosage level for compounds of formula I inducing cytoprotection in mammals, especially humans, will generally range from about 0.002 mg/kg to about 100 mg/kg, preferably from about 0.02 mg/kg to about 30 mg/kg. The dosage may be administered in single or divided individual doses.

Thus, in addition to the compounds of formula I, the pharmaceutical compositions can also contain other active ingredients, such as cyclooxygenase inhibitors, leukotriene antagonist non-steroidal anti-inflammatory drugs (NSAIDs), peripheral analgesic agents such as zomepirac, diflunisal and the like. The weight ratio of the compound of the formula I to the second active ingredient may be varied and will depend upon the effective dose of each ingredient. Generally, an effective dose of each will be used. Thus, for example, when a compound of the formula I is combined with an NSAID, the weight ratio of the compound of the formula I to the NSAID will generally range from about 1000:1 to about 1:1000, preferably about 200:1 to about 1:200. Combinations of a compound of the formula I and other active ingredients will generally also be within the aforementioned range, but in each case, an effective dose of each active ingredient should be used.

Combinations of a compound of the formula I and other active ingredients will generally be in the aforementioned ratios.

NSAIDs can be characterized into five groups:

(1) the propionic acid derivatives;
