Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).
Description

This invention relates to a tool for sampling fluids from a formation reservoir in a well and, more particularly, to a perforating and sampling tool attachable to the end of a tool string.

It is frequently necessary to obtain information about fluid in a well formation reservoir prior to actually producing the well. Measuring the pressure and temperatures of the fluid is important, but it is also desirable to obtain an actual sample of the fluid and bring that sample to the surface so that the physical characteristics of the fluid may be observed. As a result, numerous testing and sampling apparatus have been developed.

Samplers adapted for obtaining a self-contained sample have been used on wire lines. In such apparatus, the tool is lowered on a wire line and perforating guns triggered and the sample chamber filled. Because the device is used on a wire line, it is not possible for a large fluid sample to be obtained. Also, wire line sampling devices are not totally reliable and frequently the sample obtained is less than desirable.

U.S. patent no. 2,169,559 discloses a downhole tool adapted for connection to a tool string for use in a well bore, said tool comprising: packer means sealingly engageable with said well bore; perforation means for perforation of said well bore for allowing formation fluids to flow into a well annulus defined between said tool and said well bore below said packer means; a sampling device including a sampling chamber for receiving a sample of said formation fluid for subsequent removal of said sample from said well bore; and valve means for opening and closing communication between said well annulus and the sampling chamber. This apparatus includes a packer with perforating guns positioned therebelow and having a valve therein such that after the packer is set and the guns triggered, fluid from the well formation reservoir flows through the valve into a cylindrical body at the lower end of the tool string. When the drill string is raised, the valve recloses such that a volume of fluid is contained in the lower portion of the drill string. The drill string may be removed from the well bore and the sample drained for testing.

One problem with this apparatus is that hydrocarbons from the well formation are actually flowed into the tool string or to the surface. Because the formation is at a relatively high pressure, there is always a danger of a blowout of the well. Also, if sour gas is present in the sample fluid, special equipment is necessary on the surface and downhole for handling it.

The tool of the present invention is mainly characterised in that the sampling chamber is at all times isolated from the interior of the tool string and that the sample is completely enclosed in the chamber for removal from the well bore.

With this arrangement, the hydrocarbons from the well formation reservoir are never flowed into the tool string and never flowed above the packer. Because the fluid sample is totally enclosed, the sampler may be handled at the surface, and a minimum of special equipment is needed for handling the fluids in the sampler even if the sample fluid contains sour gas.

EP-A-0137735 discloses a downhole tool including an enclosed sampling chamber, but this tool is limited for use in taking samples only from previously established well bores.

According to the present invention, there is provided a downhole tool adapted for connection to a tool string for use in a well bore, said tool comprising: packer means sealingly engageable with said well bore; perforation means for perforation of said well bore for allowing formation fluids to flow into a well annulus defined between said tool and said well bore below said packer means; a sampling device including a sampling chamber; a fluid inlet to said tool from said well annulus; passageway means communicating said sampling chamber with said inlet to conduct a sample of said formation fluid to said sampling chamber; and valve means for opening and closing said passageway means communication between said well annulus and the sampling chamber; characterised in that said inlet only communicates formation fluid to said passageway, and said passageway conducts said fluid only to said sampling chamber, and wherein the sampling chamber is at all times closed to the interior of the tool string and the sample is completely enclosed in the chamber for removal from the well bore, whereby none of said formation fluid can enter the interior of the tool string.

The invention also includes a method of sampling fluid from a well formation comprising the steps of: positioning a tool in a well bore on a tool string, said tool comprising a perforating gun, a self-contained sampler adjacent said perforating gun, a fluid inlet to said tool from the well annulus, and passageway means communicating said sampler with said inlet, to conduct formation fluids to said sampler, a sampler valve therein to open and close the passageway means, and a packer adjacent said sampler;

setting said packer such that a well annulus is defined thereabove and therebelow;

actuating said gun for perforating said formation;

opening said sampler valve to admit formation fluid from said well annulus below said packer through said passageway into the sampler;

closing said sampler valve;
unsetting said packer;
removing said tool from said well bore; and
draining fluid from said sampler, characterised
in that the inlet only communicates formation fluid
to said passageway, and said passageway con-
ducts said fluid only to said sampler, a predeter-
mined volume of formation fluid being admitted to
the sampler, the sampler being closed to the inte-
rior of the tool string, and the sample being com-
pletely enclosed within the sampler for removal
from the well bore, whereby none of said formation
fluid can enter the interior of the tool string.

In a tool of the present invention, the sampling
means is self-contained and no portion of the fluids
from the formation reservoir enter the tool string.
Preferably, the sampling means is positioned below
the packer means so that the formation fluids are
never above the packer means.

In one preferred embodiment, the valve means
is opened and closed in response to a pressure
differential between an internal pressure in the tool
and a pressure in a portion of the well annulus
above the packer means. However, the valve
means may also be opened and closed by physical
manipulation.

The tool preferably comprises clean-up means
for collecting debris resulting from the perforation
and mud filtration of the reservoir prior to opening
of the valve means. In the preferred embodiment,
the perforation means is characterised by a per-
forating gun defining fluid flow passages thereth-
rough after firing thereof, and the clean-up means
is characterised by an empty casing portion dis-
posed below the gun and in fluid communication
with the fluid flow passages in the gun such that
fluid, debris and mud flow into the well casing
portion after firing of the gun. It is only after this
occurs that the valve means in the sampling means

Shear means are preferably provided for hold-
ing the valve means in a first closed position prior
to opening of the valve means, and locking means
are provided for locking the valve means in a
second closed position after closure of the valve
means.

The tool preferably further comprises gauge
means for measuring and recording at least one of
a fluid pressure and a fluid temperature in the
sampling means.

In a preferred embodiment, the sampling
means is characterized by a fluid sampling appar-
atus comprising elongated body means defining a
sampling chamber therein and sampler port means
in communication with the sampling chamber
which is opened and closed by the valve means,
and modular sampling means disposed in the sam-
pling chamber and adapted for separately entrapp-
ing a volume of fluid as the sampling chamber
fills when the sampler port means is opened by the
valve means. Preferably, second modular sampling
means are also disposed in the sampling chamber
longitudinally spaced from the first mentioned mod-
ular sampling means. The second modular sam-
pling means is adapted for entrapping another vol-
ume of fluid as the sampling chamber fills.

Drain means are also provided on the body
means for draining the sampling chamber when the
apparatus is removed from a well bore, and in a
preferred embodiment, two such longitudinally
spaced drain means are used.

Gauge means are positioned in the sampling
chamber adjacent the modular sampling means for
measuring and recording at least one of a fluid
pressure and temperature in the sampling cham-
ber.

The modular sampling means comprises me-
tering valve means openable in response to fluid
pressure in the sampling chamber and metering
means for automatically closing the metering valve
means when a predetermined volume of fluid is in
the modular sampling means. The metering means
restricts movement of the metering valve means
such that closure of the metering valve means prior
to filling the modular sampling means to the pre-
determined volume is prevented.

The method of using the tool of the present
invention for sampling fluid from the well forma-

The method also may comprise the steps of
positioning at least one sampler module in the
sample and filling the sampler module with a sepa-
rate volume of formation fluid.

The method further comprises, prior to opening
the sampler valve, the step of entrapping debris
resulting from the perforation and mud filtration
of the reservoir in a casing portion below the gun.
Preferably, the method also comprises locking the
sampler valve in a closed position after closure
thereof and measuring and recording at least one
of a temperature and a pressure in the sampler
during filling thereof.

In order that the invention may be more fully
understood, an embodiment thereof will now be
described by way of example only, with reference
to the accompanying drawings, wherein:

FIGS. 1A and 1B show an embodiment of a tool
of the present invention in position in a well
bore.

FIGS. 2A-2K illustrate a partial cross section and
partial elevation of the tool as it is run into the
well bore.

FIG. 3 is a transverse cross section taken along
lines 3-3 in FIG. 2A.

FIG. 4 shows a transverse cross section taken
along lines 4-4 in FIG. 2G.

FIGS. 5A-5F show a partial elevation and cross
section of a portion of the tool after a sampler
valve has been opened and a sample chamber
filled.

FIGS. 6A-6D show a partial elevation and cross
section of a portion of the tool after the sampler
valve has been closed and the tool removed
from the well bore and prepared for draining of
the sample.

FIGS. 7A and 7B illustrate a sampler module in
the tool after a sample chamber therein has
been filled.

FIG. 8 illustrates a lower portion of the sampler
module with a drain collar and nipple positioned
thereon for draining of a fluid sample.

Referring now to the drawings, and particularly
to FIGS. 1A and 1B, the perforate, test and sample
tool of the present invention is shown and generally
designated by the numeral 10. Tool 10 is posi-
tioned in a well casing 11 defining a well bore 12 at
the end of a tool string 14. A circulating valve 16 of
a kind known in the art is located above tool 10 in
tool string 14.

The major components of tool 10 include an
upper piston sub 18, a packer 20 of a kind known
in the art, a sampler 22, live perforating guns 24,
blank guns 26 and a bundle gauge carrier 28 of a
kind known in the art.

Circulating valve 16 is of a kind known in the
art such as the Full-Flo® hydraulic circulating
valve, manufactured by Halliburton Company.

Packer 20 is also of a kind known in the art
such as the Halliburton Champ® III retrievable
packer, manufactured by us. This packer is set by
rotating tool string 14 and setting down weight. The
packer is released by an upward pull.

Live guns 24 are also of a kind known in the art
such as used in the Vann gun, manufactured by
Vann Engineered Well Completions.

Live guns 24 include a firing head 30 such as the
GEO® Vann firing head, and a gun portion.

Referring now to FIGS. 2A-2K, details of tool
10 as the tool is run into well bore 12 are shown. In
FIG. 2A, the upper end of piston sub 18 includes
an upper adapter 34 with a threaded upper end 36
adapted for engagement to tool string 14. The
lower end of upper adapter 34 is attached to an
operating sub or cylinder 38 at threaded connec-
tion 40. A seal 42 seals between upper adapter 34
and cylinder 38.

Referring also to FIG. 2B, it will be seen that
upper adapter 34 and cylinder 38 define a longitudi-
dinal cylinder bore 44 therein. A piston means,
such as an operating piston 46, is slidably dis-
pensed in cylinder bore 44. Operating piston 46 is
the upper end of an inner tubing string 47 which
extends longitudinally substantially the length of
tool 10. Sealing means, such as piston rings 48
carried in piston ring grooves 50 on operating
piston 46, provide sealing between the piston
means and cylinder bore 44.

An upper annular shoulder 52 in upper adapter
34 and a lower annular shoulder 54 in cylinder 38
provide means for limiting the vertical movement of
piston 46 as will be further discussed herein.

Referring back to FIG. 2A, the upper end of
operating piston 46 has a threaded inner portion 56
and an external annular groove 58. A transverse
hole 60 in upper adapter 34 has a shear pin 62
positioned therethrough such that the shear pin
extends into annular groove 58 in piston 46. A plug
64 prevents communication between cylinder bore
44 and the outside of tool 10. Thus, in the position
shown in FIGS. 2A-2K, shear pin 62 provides a
means for holding piston 46 in the position shown
such that undesired vertical movement of operating
piston 46 and of the components attached thereto
is prevented. These other components include
sampler valve means described in detail herein.

A locking dog assembly 66 is positioned in
annular groove 68 of cylinder 38. As seen in FIG.
3, locking dog assembly 66 preferably comprises
three locking dogs 70 of arcuate configuration hav-
ing an outwardly facing groove 72 therein. A bias-
ing means, such as garter spring 74, is positioned
in groove 72 around each of locking dogs 70. It will
be seen that spring 74 biases locking dogs 70
inwardly toward outer surface 76 of piston 46.

Referring once again to FIG. 2A, outer surface
76 of piston 46 defines an outwardly facing annular
groove 78 therein. Annular groove 78 is adapted for
receiving locking dogs 70 of locking dog assembly
66, providing locking means for vertically locking
operating piston 46 and the components attached
thereto as will be described in more detail herein.

Referring again to FIG. 2B, the upper end of an
inner nipple 80 is connected to the lower end of
piston 46 at threaded connection 82. A seal pro-
vides sealing engagement between piston 46 and
nipple 80.

The lower end of nipple 80 is connected to an inner sealing tube 86 at threaded connection 88. A seal 90 provides sealing engagement between nipple 80 and tube 86. Tube 86 extends downwardly through cylinder 38 such that an annular volume 92 is defined therebetween.

Referring now to FIG. 2C, a lower portion of cylinder 38 defines port means, best characterized by a plurality of annulus pressure ports 94 transversely therethrough, which provide communication between annular volume 92 and a well annulus 96 defined between tool 10 and well bore 12 above packer 20, as indicated in FIG. 1A.

Upper packer body 98 of packer 20 is connected to the lower end of cylinder 38 at threaded connection 100 with a seal 102 providing threaded engagement therebetween. Packer 20 also includes a packer element 104 expandable for engagement with well bore 12 and a lower packer body 106.

Referring again to FIG. 2D, the lower end of lower packer body 106 is connected to the upper end of sealing sub 108 at threaded connection 110.

Sealing sub 108 defines an inner bore 112 longitudinally therethrough. Sealing tube 86 has an outwardly extending seal portion 114 thereon which is adapted to be in close, sliding relationship with bore 112. Sealing means, such as piston rings 116 carried in piston ring grooves 118 in seal portion 114, provide sealing engagement between seal portion 114 and bore 112 in sealing sub 108. It will be seen that the sealing means seals the lower end of annular volume 92. It will also be seen that seal portion 114 is adapted to slide within bore 112 when operating piston 46 is moved within cylinder bore 44.

The lower end of sealing tube 86 is connected to a nipple 120 at threaded connection 122, and a seal 124 provides sealing engagement between nipple 120 and sealing tube 86.

Referring now to FIG. 2E, nipple 120 is connected to inner tube 126 at threaded connection 128. A seal 130 provides sealing engagement between nipple 120 and tube 126.

The lower end of sealing sub 108 is connected to the upper end of upper sampler drain case 132 at threaded connection 134 with a seal 136 providing sealing engagement between the sealing sub and the upper sampler drain case.

Upper sampler drain case 132 has an outer surface 138 with an annular flange 140 extending outwardly therefrom. Annularly positioned around a portion of outer surface 138 adjacent flange 140 is a drain nut 142 having an annular inner shoulder 144 adapted to bear against the upper side of flange 140. It will be seen that nut 142 is substantially longitudinally fixed between flange 140 and lower face 146 of sealing sub 108. However, nut 142 is free to rotate about upper sampler drain case 132. Nut 142 defines a plurality of transverse holes 148 therethrough and also has a threaded inner surface 150 below annular shoulder 144.

Below nut 142 and annularly positioned around upper sampler drain case 132 is an upper sampler drain valve 152. Upper sampler drain valve 152 has a sleeve 154 which extends upwardly and has an externally threaded portion 156 threadingly engaged with threaded inner surface 150 of nut 142. Upper sampler drain valve 152 defines a threaded transverse hole 158 therein.

Tube 126 extends through upper sampler drain case 132 such that an annular cavity 160 is defined therebetween. As will be more fully explained herein, cavity 160 forms the upper portion of a sampling chamber 194 within sampler 22. It will be seen that seals 118 provide a sealing means for sealing the upper end of cavity 160 and sampling chamber 194.

Upper sampler drain 132 defines a transverse hole 162 therethrough in communication with cavity 160. As shown in FIG. 2E, upper sampler drain valve 152 is positioned such that seals 164 and 166, disposed in grooves 168 and 164, respectively, seal off hole 162 and prevent communication between cavity 160 and the well annulus. Another seal 172 is carried in another groove 174 in upper sampler drain valve 152. Seal 172 is positioned below hole 158 in drain valve 152. As will be discussed in more detail herein, drain valve 152 may be moved upwardly such that hole 158 is aligned with hole 162, thereby providing a drain means for allowing fluid communication between cavity 160 and the exterior of tool 10.

The lower end of upper sampler drain case 132 is connected to a drain adapter 176 by threaded connection 178. Seal 180 provides sealing engagement between upper sampler drain case 132 and drain adapter 176. In the closed position of upper sampler drain valve 152 shown in FIG. 2E, it will be seen that the upper sampler drain valve is positioned adjacent upwardly directed face 182 of drain adapter 176.

Referring now to FIG. 2F, drain adapter 176 is connected to sampler case 183 of upper sampler-gauge assembly 184 at threaded connection 186, and a seal 188 provides sealing engagement therebetween. The lower end of upper sampler-gauge assembly 184 is connected to hollow casing 190 by a coupling 192 in a manner known in the art. Tube 126 extends down through sampler 22 defining sampling chamber 194 therebetween, or which cavity 160 is an upper portion. Tube 126 may be a single piece or it may be formed of a plurality of pieces connected together in any known manner.

Referring now to FIG. 2G, casing 190 is connected to sampler body 196 of lower sampler-
gauge assembly 198 at threaded connection 200. A seal 202 provides sealing engagement between casing 190 and sampler body 196.

The construction of lower sampler-gauge assembly 198 will now be discussed in detail. It should be understood that upper sampler-gauge assembly 184 is of substantially identical construction and for this reason the details of the upper sampler-gauge assembly have not been shown. It should also be understood that the number of casings 190 and the necessary couplings 192 to connect them together may be varied as desired to arrive at a predetermined volume of sampling chamber 194.

Sampler body 196 of lower sampler-gauge assembly 198 is a substantially tubular member and tube 126 extends theerethrough. As already indicated, tube 126 may be of multi-piece construction such as a plurality of tubes 126 interconnected by couplings 204 at threaded connections 206 and 208 with sealing provided by seals 210 and 212 as shown in FIGS. 2G and 2H.

Referring now to FIGS. 2G and 4, modular sampling means preferably characterized by a pair of elongated sampler modules 214 are longitudinally positioned in annular sampling chamber 194 between sampler body 196 and tube 126. Preferably, sampler modules 214 are spaced at approximately 180°. Also longitudinally positioned in sampling chamber 194 are a pair of elongated testing gauges 216. Testing gauges 216 are of a kind known in the art and provide gauge means for measuring and recording pressure and/or temperature. Sampler modules 214 and testing gauges 216 have substantially the same external dimensions and are installed in substantially the same way. The actual internal details of testing gauges 216 are not necessary for this disclosure and are omitted for simplicity. As shown in FIG. 4, testing gauges 216 are preferably spaced approximately 90° from adjacent sampler modules 214.

Referring again to FIG. 2G, the upper end of each sampler module 214 (and also of each testing gauge 216) is supported by upper support means comprising an annular support ring 218 defining a plurality of holes 220 with corresponding concentric countersinks 222 thereabove. In the preferred embodiment, there are four such pairs of holes 220 and countersinks 222, one set for each sampler module 214 and each testing gauge 216, although the number of modules and gauges may vary as desired. Support ring 218 is separated from the bottom of the lowermost casing 190 by annular large cushion 224.

The upper support means also comprises a hanger 226 extending downwardly through hole 220 and connected to adapter 220 at threaded connection 230. A nut 232 locks hanger 226 to adapter 228. Hanger 226 has an enlarged head portion 234 positioned in countersink 222, and a small cushion 236 is positioned above the head portion and two small cushions 236 are positioned therebelow. A plug 238 keeps head portion 234 and cushions 236 in place within countersink 222.

A drain cover 240 is connected to adapter 228 at threaded connection 242 and connected to drain nipple 244 at threaded connection 246. A seal 248 provides sealing engagement between drain cover 240 and drain nipple 244. A longitudinal passageway 250 is defined through drain nipple 244.

The lower end of drain nipple 244 is connected to sample case 252 at threaded connection 254 with a seal 256 providing sealing engagement therebetween. Sample case 252 defines an elongated central cavity 258 therein.

As seen in FIG. 2H, a piston 260 is originally disposed at the lower end of central cavity 258 in sample case 252. Sealing engagement is provided between piston 260 and sealing case 252 by upper piston ring 262 and lower piston ring 264.

A metering case 266 is connected to the lower end of sample case 252 at threaded connection 268. A seal 270 provides sealing engagement between metering case 266 and sample case 252.

Metering case 266 defines an elongated central cavity 272 therein with a transverse port of hole 274 in communication therewith. A countersink forms a flat shoulder 276 which extends adjacent hole 274.

Slidably disposed in central cavity 272 in metering case 266 is a metering valve 278. Metering valve 278 has an elongated annular recess 280 thereon such that an annulus 282 is defined between metering valve 278 and the inner wall of metering case 266. In the position shown, annulus 282 is in fluid communication with transverse hole 274.

Metering valve 278 also defines a passageway 284 therein of substantially T-shaped cross section which extends from recess 280 at its lower end to top face 286 of metering valve 278 at its upper end. It will thus be seen that passageway 284 provides fluid communication between annulus 282 and the bottom of piston 260 and that annulus 282 and passageway 284 provide passageway means between central cavity 258 in sealing case 252 and central cavity 272 in metering case 266. Above recess 280 a pair of spaced sealing rings 288 are carried on the exterior of metering valve 278 in ring grooves 290. The importance of the spacing between sealing rings 288 will become more apparent hereinafter. Another sealing ring 292 is carried in a groove 294 which is positioned below groove 280 on metering valve 278. It will thus be seen that the portion of central cavity 272 above sealing ring 292 is separated from the portion of central cavity 272
below sealing ring 292.

The lower end of metering case 262 is connected to metering nipple 296 at threaded connection 298. A seal 300 provides sealing engagement between metering case 266 and metering nipple 296.

Metering nipple 296 defines a longitudinal passageway 302 therethrough with orifice means such as a Visco-jet 304 disposed across the upper end thereof. Visco-jet 304 is of a kind known in the art and has a small, precisely-sized orifice 306 therethrough which provides restricted communication between the lower portion of central cavity 276 and metering case 266 and passageway 302.

The lower end of metering nipple 296 is connected to air chamber 308 at threaded connection 310 with a seal 312 providing sealing engagement therebetween. Air chamber 308 defines an elongated cavity 314 therein which is in communication with passageway 302 in metering nipple 296.

Referring now to FIG. 21, cavity 314 in air chamber 308 has a closed lower end 316.

Air chamber 308 has a downwardly extending stud portion 318 which forms a lower portion of the air chamber. Stud portion 318 extends into a hole 320 defined in a lower guide plate 322. There are a plurality of holes 320, one for each sampler module 214 and each testing gauge 216. Lower guide plate 322 thus provides lower support means for sampler modules 214 and testing gauges 216.

Referring again to FIG. 4, a plurality of guide posts 324 provide additional support means extending longitudinally between guide plate 322 and support ring 218. Guide posts 324 are engaged with guide plate 322 and support ring 218 such that a rigid assembly is formed. This allows all of the sampler modules 214 and testing gauges 216 to be positioned in, and removed from, sampling chamber 194 at one time.

Referring again to FIG. 21, the lower end of sampler body 196 is connected to lower drain adapter 326 at threaded connection 328. A seal 330 provides sealing engagement between sampler body 196 and drain adapter 326.

An annular cushion 332' separates guide ring 322 from the top of drain adapter 326.

The lower end of drain adapter 326 is connected to lower sampler drain case 332 at threaded connection 334 with seal 336 providing sealing engagement therebetween.

The entire drain valve assembly around lower sampler drain case 332 is substantially identical to that around upper sampler drain case 132. Lower sampler drain case 332 has an outer surface 338 with an annular flange 340 extending outwardly therefrom. Annularly positioned around a portion of outer surface 338 adjacent flange 340 is a drain nut 342 having an annular inner shoulder 344 adapted to bear against the upper side of flange 340. It will be seen that nut 342 is substantially longitudinally fixed between flange 340 and lower face 346 of drain adapter 326. However, nut 342 is free to rotate about lower sampler drain case 332. Nut 342 defines at least one transverse hole 348 therethrough and also has a threaded inner surface 350 below annular shoulder 344.

Below nut 342 and annularly positioned around lower sampler drain case 332 is a lower sampler drain valve 352. Lower sampler drain valve 352 has a sleeve 354 which extends upwardly and has an externally threaded portion 356 therethreadingly engaged with threaded inner surface 350 of nut 342. Lower sampler drain valve 352 defines a threaded transverse hole 358 therein.

Tube 126 continues to extend downwardly through sampler 22, and the lower end or tube 126 is connected to sampler valve means best characterized by sampler valve 360 at threaded connection 362. A seal 364 provides sealing engagement between tube 126 and valve 360.

An annular cavity 366 is thus defined between lower sampler drain case 332 and the assembly formed by tube 126 and valve 360. It will be seen that cavity 366 forms a lower portion of sampling chamber 194 within sampler 22.

Lower sampler drain case 332 defines a transverse hole 368 therethrough in communication with cavity 366. As shown in FIG. 21, lower sampler drain valve 352 is positioned such that seals 370 and 372 disposed in grooves 374 and 376, respectively, seal off hole 368 and prevent communication between cavity 366 and the well annulus. Another seal 378 is carried in another groove 380 in lower sampler drain valve 352. Seal 378 is positioned below hole 358 in drain valve 352. As will be discussed in more detail herein, drain valve 352 may be moved upwardly such that hole 358 is aligned with hole 368, thereby providing drain means for allowing fluid communication between cavity 366 and the exterior of tool 10.

Referring now to FIG. 22, the lower end of lower sampler drain case 332 is connected to a drain coupling 382 at threaded connection 384. Seal 386 provides sealing engagement between lower sampler drain case 332 and drain coupling 382. In the closed position of upper sampler drain valve 352 shown in FIGS. 21 and 22, it will be seen that the sampler drain valve is positioned adjacent upwardly directed face 388 of drain coupling 382.

The lower end of drain coupling 382 is connected to the upper end of valve body 390 at threaded connection 392, with a seal 394 providing sealing engagement therebetween.

Annularly disposed around valve body 390 is a screen support 396 having a plurality of openings 398 therethrough. Valve body 390 has a recessed...
outer surface 400 spaced inwardly from screen support 396 such that an annular volume 402 is defined therebetween.

Annularly spaced outwardly from screen support 396 is a filter screen 404 which is attached at its upper end to screen support 396 by weld 406 and at its lower end to screen support 396 by weld 408, as seen in FIG. 2K. It will be seen that another annular volume 410 is defined between filter screen 404 and screen support 396.

Valve 360 has a first outer surface 412 spaced inwardly from inner surface 414 of valve body 390 such that an annular passageway 416 is defined therebetween. Valve 360 also has a second outer surface 418 adapted to be in close, spaced and sliding relationship with inner surface 414 of valve body 390. Upper valve seals 420, intermediate valve seals 422 and lower valve seals 424 are carried in grooves 426, 428 and 430, respectively, in outer surface 418 of valve 360. Thus, a means is provided for sealing engagement between valve 360 and inner surface 414 of valve body 390, as will be described in more detail herein.

Between upper valve seals 420 and intermediate valve seals 422, outer surface 418 of valve 360 has a serrated portion 432. Adjacent serrated portion 432, as shown in FIG. 2J, and transversely extending through the screen mandrel is a sampler port means, such as at least one sampler port 434. Serrated portion 432 acts as an indicator means, visible through sampler port 434, for indicating that valve 360 is properly positioned during assembly of tool 10.

Referring again to FIG. 2K, the lower end of valve body 390 is connected to a gun coupling or lower adapter 436 at threaded connection 438. A seal 440 provides sealing engagement between seal mandrel 390 and lower adapter 436. Lower adapter 436 has an internally threaded opening 442 which is adapted for engagement with firing head 30, as best shown in FIG. 1B.

A study of FIGS. 2A-2K will show that sealing sub 108, upper sampler drain case 132, drain adapter 176, sampler case 183, coupling 192, casing 190, sampler body 196, drain adapter 326, lower sampler drain case 332, coupling 382 and valve body 390 provide elongated body means, generally in the form of an annular outer body portion, for sampler 22.

Operation Of The Invention

The components of tool 10 are in the configuration shown in FIGS. 2A-2K when the tool is run into well bore 12 at the end of tool string 14. In this run-in position of tool 10, metering chamber 272, shown in FIG. 2H, is filled with a viscous fluid such as oil. Air chamber 314, shown in FIGS. 2H and 2I, is initially empty. That is, air chamber 314 is originally filled with atmospheric air. Also initially empty is central cavity 258 in sample case 252, shown in FIGS. 2G and 2H.

Once tool 10 is positioned in well bore 12 at the desired location, as illustrated in FIGS. 1A and 1B, circulating valve 16 is closed and packer 20 is actuated as previously described such that packer element 104 sealingly engages well bore 12 as shown by phantom lines in FIG. 1A. Firing head 30 is then triggered, and the gun portion of live guns 24 fire to perforate casing 11 adjacent the formation to be sampled so that well fluids will flow from the formation. For the Vannung previously mentioned, firing head 30 is triggered by pressurizing the well annulus and the internal portion of tool 10. However, other perforating guns may use manipulation of the tool string in addition to, or instead of, applying pressure. The invention is not intended to be limited to a particular type of perforating gun.

When packer 20 is engaged, a sealed well annulus 444 is defined around the portions of tool 10 below packer 20, as shown in FIGS. 1A and 1B. When live guns 24 are fired, fluid enters blank guns 26 such that inner cavity 446 therein is filled with fluid, well debris and mud filtration of the reservoir. The majority of the debris resulting from perforation of well bore 12 and the mud filtration will either fall to the bottom of annulus 444 or go into cavity 446 rather than enter sampler 22 once the sampler subsequently is opened. Thus, a clean-up means is provided for cleaning wall annulus 444 below packer 20 prior to opening sampler 22.

When it is desired to take the fluid sample, pressure in well annulus 96 above packer 20 is lowered below the internal pressure in tool 10. When the well annulus pressure is lowered, it will be seen that the pressure in annular volume 92, best shown in FIGS. 2B and 2C, is lowered because annular volume 92 is in communication with well annulus 96 through annulus pressure ports 94. Consequently, inner string 47 is moved downwardly as shown in FIGS. 5A-5F by the downward force resulting from the pressure differential acting on operating piston 46 such that shear pins 62 are sheared. Operating piston 46 is thus moved downwardly until it contacts lower annular shoulder 54 in cylinder 38 as seen in FIG. 5A.

Although the above description of a pressure responsive operating piston 46 is a preferred embodiment, operating piston 46 could also be actuated by applying downward force on the piston through a tubing string 447 of a kind known in the art connected to threaded portion 56 at the upper end of the operating piston. The invention is not intended to be limited to a pressure actuated operating piston 46.
Referring now to FIG. 5 E/F (or 2J), regardless of how operating piston 46 is actuated, valve 360 is correspondingly moved downwardly within valve body 390 such that upper valve seals 420 are moved below sampler port 434, thus placing the sampler port in fluid communication with annular passageway 416 and therefore in communication with annular cavity 366, the lower portion of sampling chamber 194.

Well fluid in the well annulus enters sampler 22 through filter screen 404, flowing through annular volume 410, openings 398, annular volume 402, sampler port 434 and annular passageway 416 into sampling chamber 194. Sampling chamber 194 gradually fills, upwardly compressing the lower pressure air therein. Sampling chamber 194 thus provides a large volume of sample fluid when tool 10 is raised out of well bore 12.

Referring now to FIGS. 2G, 2H, 4, 5B and 5C, the filling of each sampler module 214 will be discussed. It will be seen that hole 274 in metering case 266 is in fluid communication with, and actually forms a part of, sampling chamber 194. Thus, as sampling chamber 194 fills, fluid enters hole 274, flowing through the passageway means characterized by annulus 282 and passageway 284, coming in contact with the bottom of piston 260, as best seen in FIG. 2H. The fluid pressure forces piston 260 upwardly in central cavity 258 of sampler case 252, compressing the air in cavity 258. Piston 260 continues to move upwardly until it contacts lower face 448 of drain nipple 244, as best seen in FIG. 5B. Thus, a sampler module chamber 450 is defined below piston 260 in sampling case 252. Chamber 450 is filled with fluid which may then be drained once tool 10 is brought out of well bore 12.

It will be clear to those skilled in the art that the two sampler modules 214 in lower sampler-gauge assembly 198 fill before the corresponding sampler modules 214 in upper sampler-gauge assembly 184. Along with differences in the temperature and pressure, as measured by upper and lower testing gauges 216, the fluid samples in sample module 214 provide important information relating to the flow rate of the formation being tested, as well as the type of fluid in the formation which is essential for reservoir evaluation.

As piston 260 moves upwardly, filling sampler module chamber 450, fluid pressure also forces metering valve 278 downwardly in metering case 266. The oil present in metering chamber 272 provides resistance to this downward motion of metering valve 278, because the oil must pass through small orifice 306 in Visco-jet 304 before being discharged through passageway 302 into cavity 314 in air chamber 308. Eventually, metering valve 278 moves all the way downwardly until it contacts lower shoulder 452 in metering case 266, thus displacing all of the oil out of metering chamber 272 and compressing the air in air chamber 308.

By proper sizing of all of the components, complete downward movement of metering valve 278 does not occur until after complete upward movement of piston 260. In other words, sampler module chamber 450 is completely filled before metering valve 278 reaches shoulder 452. It will be seen that, once metering valve 278 has reached its downwardmost position, sealing rings 288 close off hole 274 in metering case 266. Thus, once sampler module chamber 450 is completely filled with a sample fluid, sampler module 214 is closed. Thus, a metering means is provided for automatically closing the metering valve means when a predetermined fluid volume is in sampler module chamber 450.

Once metering chamber 194 and each sampler module chamber 450 are filled, it is necessary to close sampler port 434 prior to removing tool 10 from well bore 12. Referring now to FIGS. 6A-6D, closure of sampler port 434 is accomplished by lowering the internal pressure in tool 10 and repressurizing well annulus 96. It will be seen that this causes an upward pressure differential on operating piston 46 resulting in an upward force which causes the piston to move upwardly until it contacts upper annular shoulder 52 of upper adapter 34. It will be noted that operating piston 46 is thus raised above its original position such that groove 72 is aligned with locking dog assembly 66. Garter spring 74 forces locking dogs radially inwardly such that they engage groove 72 locking operating piston 46, and thus inner string 47, into the position shown in FIGS. 6A-6D.

Once again, it is noted that the invention is not intended to be limited to a pressure responsive operating piston 46. Piston 46 could be raised by lifting on tubing string 447 connected to the operating piston at threaded portion 56 thereof.

As operating piston 46 is moved upwardly by either applying a pressure differential or lifting on a tubing string 447, valve 360 is also moved upwardly above its original position. In this newly raised position, intermediate valve seals 422 on valve 360 are located above sampler port 434. In this way, intermediate valve seals 422 and lower valve seals 424 sealingly close sampler port 434.

Because valve 360 is connected to operating piston 46, it will be seen that locking dog assembly 66 provides a means for locking valve 360 in a sealingly closed position.

After valve 360 is closed, packer 20 may be disengaged and circulating valve 16 reopened so that tool string 14 and tool 10 may be retrieved from well bore 12.
Once tool 10 is out of the well bore, the test fluid in sampler 22 may be drained therefrom. First, draining the fluid from large sampling chamber 194 will be discussed.

Referring to FIG. 6B, a drain line 453 with appropriate valving is connected to hole 158. Upper sampler drain valve 152 is then moved upwardly by rotation of nut 142. When sleeve 154 of upper sampler drain valve 152 contacts flange 140 on upper sampler drain case 132, hole 158 in upper sampler drain valve 152 is aligned with hole 162 in the upper sampler valve mandrel. Thus, cavity 160 which is the upper portion of sampler chamber 194 may be easily drained or vented.

Referring now to FIG. 6C, another drain line 453 with valving is connected to hole 358 of lower sampler drain valve 352, and the lower sampler drain valve is raised by rotation of nut 342 until sleeve 354 contacts flange 340 on lower sampler drain case 332. When this occurs, hole 358 in lower sampler drain valve 352 is aligned with hole 368 in the lower sampler valve mandrel such that cavity 366 which is the lower portion of sampling chamber 194 may be drained or vented as desired.

Once sampling chamber 194 has been completely drained, sampler 22 may be disassembled such that each sampler module 214 may be removed therefrom and drained separately. Because each sampler module 214 is a self-contained unit, the sampler modules are easily transported and may be drained anywhere desired, such as in a testing laboratory.

The draining of a typical sampler module 214 will now be discussed. Initially, of course, piston 360 and metering valve 278 are in the positions shown in FIGS. 7A and 7B with hole 274 sealingly closed. Referring also to FIG. 8, a drain collar 454 is annularly positioned around metering case 266 such that a threaded opening 456 in drain collar 454 is substantially aligned with hole 274 in metering case 266. A surface drain nipple 458 with an externally threaded surface 460 is threadingly engaged with threaded hole 456 in drain collar 454.

Surface drain nipple 458 is threaded into drain collar 454 such that inner face 462 of the surface drain nipple contacts annular shoulder 276 on metering case 266. A seal provides sealing engagement between surface drain nipple 458 and shoulder 276. A drain line 465 with appropriate valving may be connected to threaded opening 466 on the outer end of surface drain nipple 458.

Once drain collar 454 and surface drain nipple 458 are thus positioned, metering nipple 296 and air chamber 308 are removed from sampler module 214 by breaking threaded connection 298. An opening tool or nipple 468, with an externally threaded portion 470 is threadingly engaged with metering case 266 to form a new threaded connection 471 after removal of metering nipple 296.

Opening nipple 468 has pin means such as an elongated pin portion 472 thereon which extends into metering case 266 past shoulder 452, thus coming in contact with lower end 474 of metering valve 278. As opening nipple 468 is threaded into metering case 266 for a complete threaded connection 298, it will be seen that pin portion 472 displaces metering valve 278 upwardly until annulus 282 is once again in fluid communication with hole 274 and thus in fluid communication with passageway 476 of surface drain nipple 458. Fluid is thus free to flow out of sampler module chamber 450 until piston 260 again reaches its lowermost position in contact with upper face 478 of metering case 268. Thus, a safe and reliable means of draining each sampler module 214 is provided.

It will be seen, therefore, that the perforate, test and sample tool and the sampler of the present invention are well adapted to carry out the ends and advantages mentioned as well as those inherent therein. While a presently preferred embodiment of the invention has been described for the purposes of this disclosure, numerous changes in the arrangement and construction of parts may be made by those skilled in the art.

Claims

1. A downhole tool (10) adapted for connection to a tool string (14) for use in a well bore (12), said tool comprising: packer means (20) sealingly engageable with said well bore; perforation means (24) for perforation of said well bore for allowing formation fluids to flow into a well annulus defined between said tool and said well bore below said packer means; a sampling device (22) including a sampling chamber (194); a fluid inlet (434) to said tool from said well annulus; passageway means (416) communicating said sampling chamber with said inlet to conduct a sample of said formation fluid to said sampling chamber; and valve means (360) for opening and closing said passageway means communication between said well annulus and the sampling chamber; characterised in that said inlet only communicates formation fluid to said passageway, and said passageway conducts said fluid only to said sampling chamber, and wherein the sampling chamber (194) is at all times closed to the interior of the tool string (14) and the sample is completely enclosed in the chamber for removal from the well bore, whereby none of said formation fluid can enter the interior of the tool string.
2. A tool according to claim 1, characterised in that the said valve means (360) is opened and closed in response to a pressure differential between an internal pressure in said tool and a pressure in a portion of a well annulus (96) above said packer means (20).

3. A tool according to claim 1 or 2, characterised by shear means (62) for holding said valve means (360) in a closed position prior to opening of the valve means.

4. A tool according to claim 1, 2 or 3, characterised by locking means (66, 78) for locking said valve means (360) in a closed position after closure of the valve means.

5. A tool according to claim 1, 2, 3 or 4, characterised in that the said sampling means (22) comprises angularly spaced sampling modules (214) adapted for entrapping separate samples of said fluid.

6. A tool according to claim 5, characterised by gauge means (216) adjacent said sampling modules (214) for measuring fluid pressure and/or temperature adjacent said sampling modules.

7. A tool according to any of claims 1 to 6, characterised by clean-up means for collecting debris resulting from said perforation.

8. A tool according to claim 7, wherein said perforation means comprises a perforating gun (24) defining fluid flow passages therethrough after firing thereof; and said clean-up means is characterised by an empty casing portion (446) disposed below said gun and in fluid communication with said fluid flow passages such that fluid and debris flow into said casing portion after firing of said guns.

9. A method of sampling fluid from a well formation comprising the steps of:

   positioning a tool (10) in a well bore (12) on a tool string (14), said tool comprising a perforating gun (24), a self-contained sampler (22) adjacent said perforating gun, a fluid inlet (434) to said tool from the well annulus, and passageway means (416) communicating said sampler (22) with said inlet, to conduct formation fluids to said sampler, a sampler valve (360) therein to open and close the passageway means, and a packer (20) adjacent said sampler;

   actuating said gun for perforating said formation;

   opening said sampler valve to admit formation fluid from said well annulus below said packer through said passageway into the sampler (22);

   closing said sampler valve;

   unsetting said packer;

   removing said tool from said well bore; and

   draining fluid from said sampler, characterised in that the inlet only communicates formation fluid to said passageway, and said passageway conducts said fluid only to said sampler, a predetermined volume of formation fluid being admitted to the sampler, the sampler being closed to the interior of the tool string, and the sample being completely enclosed within the sampler for removal from the well bore, whereby none of said formation fluid can enter the interior of the tool string.

10. A method according to claim 9, wherein said sampler valve is a pressure responsive sampler valve; said step of opening said sampler valve comprises lowering pressure in said well annulus above said packer for creating a pressure differential across said sampler valve; and said step of closing said valve comprises raising pressure in said well annulus above said packer and lowering pressure in said tool for providing a reverse pressure differential across said sampler valve.

11. A method according to claim 9 or 10, wherein said sampler comprises two or more individual sampler modules (214) disposed therein and further comprising the step of filling said sampler modules with separate volumes of formation fluid.

12. A method according to claim 9, 10 or 11, further comprising, prior to opening said sampler valve, the step of entrapping debris resulting from said perforation and mud filtration in a casing portion below said gun.

Patentansprüche

1. Bohrlochwerkzeug (10), das zur Verbindung mit einem Werkzeugstrang (14) zur Verwendung in einer Bohrung (12) eingerichtet ist, enthaltend: Packermittel (20), die abdichtend an die Bohrung anlegbar sind; Perforiermittel (24) zur Perforierung der Bohrung, die Formationsfluiden das Einführen in einen Bohrungsringspalt ermöglicht, der zwischen dem Werkzeug und der Bohrung unterhalb der Packer-
mittel bestimmt ist; eine Probenahmeeinrich-
tung (22) mit einer Probenkammer (194); ein
Fluideinlaß (434) von dem Bohrungsringsraum
in das Werkzeug; Durchgangskanalmittel (416),
die die Probenkammer mit dem Einlaß verbin-
den, um der Probenkammer eine Probe des
Formationsfluids zuzuleiten; und Ventilmittel
(360) zum Öffnen und Schließen der
Durchgangskanalmittel-Verbindung zwischen
dem Bohrungsringsraum und der Probenka-
mmer; dadurch gekennzeichnet, daß der Einlaß Fo-
rmationsfluid nur dem Durchgangskanal zuführt
und der Durchgangskanal das Fluid nur der
Probenkammer zuleitet, und daß die Proben-
kammer (194) zu jeder Zeit gegenüber dem
Inneren des Werkzeugstranges (14) geschlos-
sen und die Probe zur Entnahme aus der
Bohrung vollständig in die Kammer einge-
schlossen ist, wodurch kein Formationsfluid in
das Innere des Werkzeugstranges eintreten
cann.

2. Werkzeug nach Anspruch 1, dadurch gekenn-
zeichnet, daß die Ventilmittel (360) unter An-
sprechern auf eine Druckdifferenz zwischen ei-
nem Innendruck in dem Werkzeug und einem
Druck in einem Teil eines Bohrungsringsraums
(96) oberhalb der Packermittel (20) geöffnet
und geschlossen werden.

3. Werkzeug nach Anspruch 1 oder 2, gekenn-
zeichnet durch Schermittel (62), durch die die
Ventilmittel (360) vor Öffnung der Ventilmittel
in einer geschlossenen Stellung gehalten sind.

4. Werkzeug nach Anspruch 1, 2 oder 3, gekenn-
zeichnet durch Verriegelungsmittel (66, 78),
durch die die Ventilmittel (360) nach Schließ-
ung der Ventilmittel in einer geschlossenen
Stellung verriegelt sind.

5. Werkzeug nach Anspruch 1, 2, 3 oder 4, da-
durch gekennzeichnet, daß die Probenahme-
mittel (22) im Winkelabstand angeordnete Pro-
benahmemodule (214) aufweisen, die zum Ein-
schluß getrennter Proben des Fluids eingerich-
tet sind.

6. Werkzeug nach Anspruch 5, gekennzeichnet
durch den Probenahmemodulen (214) benach-
barte Meßmittel (216) zur Messung des Fluid-
druckes und/oder der Temperatur neben den
Probenahmemodulen.

7. Werkzeug nach einem der Ansprüche 1 bis 6,
gekennzeichnet durch Stäuberungsmittel zur
Aufnahme von Bruchstücken, die von der Per-
forierung herrühren.

8. Werkzeug nach Anspruch 7, dadurch gekenn-
zeichnet, daß die Perforiermittel eine Perfo-
rierkanone (24) aufweisen, in der nach ihrem
Abfeuern durchgehende Fluid-Durchflußkanäle
bestimmt sind; und daß die Stäuberungsmittel
durch ein leeres Mantelteil (446) gekennzeich-
net sind, das unterhalb der Kanone angeordnet
ist und mit den Fluid-Durchflußkanälen in
Fluidverbindung steht, derart, daß nach dem
Abfeuern der Kanonen Fluid und Bruchstücke
in das Mantelteil einfließen.

9. Verfahren zur Probenahme von Fluid aus einer
Bohrungsformation, enthaltend die Schritte:
Positionieren eines Werkzeugs (10) in einer
Bohrung (12) an einem Werkzeugstrang (14),
das eine Perforierkanone (24) aufweist, sowie
einen in sich geschlossenen Probenehmer (22)
nach der Perforierkanone, einen Fluideinlaß
(434) vom Bohrungsringsraum in das Werkzeug,
und Durchgangskanalmittel (416), die den Pro-
benahmer (22) mit dem Einlaß verbinden, um
dem Probenehmer Formationsflüsse zuzuleiten,
ein Probenehmerventil (360) darin, um die
Durchgangskanalmittel zu öffnen und zu
schließen; und einen Packer (20) neben dem
Probenehmer;
Setzen des Packers, so daß darüber und dar-
unter ein Bohrungsringsraum bestimmt wird;
Betätigen der Kanone zum Perforieren der For-
mation;
Öffnen des Probenehmerventils, um Forma-
tionsfluid aus dem Bohrungsringsraum unterhalb
des Packsers durch den Durchgangskanal in
den Probenehmer (22) einzulassen;
Schließen des Probenehmerventils;
Lösen des Packers;
Entfernen des Werkzeugs aus der Bohrung;
und
Ablassen des Fluids aus dem Probenehmer,
dadurch gekennzeichnet, daß der Einlaß For-
mationsfluid nur dem Durchgangskanal zuführt
und der Durchgangskanal Fluid nur dem
Probenehmer zuleitet, wobei ein vorgegebenes
Volumen des Formationsfluids in den Probene-
hmer eingelassen wird, der Probenehmer ge-
genüber dem Inneren des Werkzeugstranges
geschlossen wird und die Probe zur Entnahme
aus der Bohrung vollständig in den Probeneh-
mers eingeschlossen wird, wodurch kein Forma-
tionsfluid in das Innere des Werkzeugstranges
eintreten kann.

10. Verfahren nach Anspruch 9, dadurch gekenn-
zeichnet, daß das Probenehmerventil ein auf
Druck ansprechendes Probenehmerventil ist;
daß der Schritt der Öffnung des Probenehmerventils umfaßt, daß der Druck im Bohrungsringraum oberhalb des Packers herabgesetzt wird, um eine Druckdifferenz an dem Probenehmerventil zu erzeugen; und daß der Schritt der Schließung des Ventils umfaßt, daß der Druck im Bohrungsringraum oberhalb des Packers erhöht und innerhalb des Werkzeuges herabgesetzt wird, um an dem Probenehmerventil eine entgegengesetzte Druckdifferenz bereitzustellen.

Revendications

1. Outil de fond de puits (10) adapté pour être connecté à un train d'outil (14) destiné à être utilisé dans un alésage (20) de puits, ledit outil comportant : des moyens formant packer (12) pouvant venir en contact de manière étanche avec ledit alésage de puits; des moyens de perforation (24) destinés à perforer ledit alésage de puits pour permettre à des fluides de la formation de s'écouler jusque dans un annulus de puits défini entre ledit outil et ledit alésage de puits en dessous des dés Iris moyens formant packer; un dispositif d'échantillonnage (22) comportant une chambre (194) d'échantillonnage; une entrée (434) de fluide vers ledit outil à partir dudit annulus de puits; des moyens (416) formant passage mettant en communication ladite chambre d'échantillonnage avec ladite entrée pour diriger un échantillon dudit fluide de formation vers ladite chambre d'échantillonnage; et des moyens (360) formant vanne destinée à ouvrir et fermer ladite communication des moyens formant passage entre ledit annulus de puits et la chambre d'échantillonnage; caractérisé en ce que ladite entrée met en communication le fluide de formation uniquement vers ledit passage, et ledit passage dirige ledit fluide uniquement vers ladite chambre d'échantillonnage, la chambre d'échantillonnage (194) étant à tout moment fermée vers l'intérieur du train d'outil (14) et l'échantillon étant complètement enfermé dans la chambre pour être enlevé de l'alésage du puits, de telle sorte que ledit fluide de formation ne peut pas entrer à l'intérieur du train d'outil.

2. Outil selon la revendication 1, caractérisé en ce que lesdits moyens formant vanne (360) sont ouverts et fermés en réponse à une pression différentielle existant entre une pression interne dudit outil et une pression s'exerçant dans une partie d'un anulus (96) de puits situé au-dessus desdits moyens (20) formant packer.

3. Outil selon la revendication 1 ou 2, caractérisé en ce qu'il comporte des moyens (62) à cisaillement destinés à maintenir lesdits moyens (360) formant vanne dans une position fermée avant d'ouvrir les moyens formant vanne.

4. Outil selon la revendication 1, 2 ou 3, caractérisé en ce qu'il comporte des moyens de blocage (66, 78) pour bloquer lesdits moyens (360) formant vanne dans une position fermée après fermeture des moyens formant vanne.

5. Outil selon la revendication 1, 2, 3 ou 4, caractérisé en ce que lesdits moyens (22) d'échantillonnage comportent des modules (214) d'échantillonnage écartés angulairement adaptés pour piéger des échantillons séparés dudit fluide.

6. Outil selon la revendication 5, caractérisé en ce qu'il comporte des moyens (216) formant jauges adjacents auxdits modules (214) d'échantillonnage pour mesurer la pression du fluide et/ou la température du fluide au voisinage desdits modules d'échantillonnage.

7. Outil selon l'une quelconque des revendications 1 à 6, caractérisé en ce qu'il comporte des moyens de nettoyage destinés à collecter les débris résultant de ladite perforation.

8. Outil selon la revendication 7, dans lequel lesdits moyens de perforation comportent un canon perforateur (24) définissant des passages d'écoulement de fluide à travers lui après mise à feu, et les moyens de nettoyage sont caractérisés par une partie (446) de boîtier vide disposés en dessous du canon et en communication de fluide avec lesdits passages d'écoulement de fluide de telle sorte que le fluide et les débris s'écoulent jusque dans la partie du boîtier après mise à feu du canon.
9. Procédé d'échantillonnage de fluide à partir d'une formation de puits comportant les étapes consistant à :
positionner un outil (10) dans un alésage (12) de puits sur un train d'outil (14), ledit outil comportant un canon de perforation (24), un échantillonneur (22) autonome adjacent audit canon perforateur, une entrée (434) de fluide vers ledit outil à partir de l'annulus de puits, et des moyens (416) formant passage faisant communiquer ledit échantillonneur (22) avec ladite entrée, pour diriger des fluides de la formation vers ledit échantillonneur, une vanne (360) d'échantillonneur située à l'intérieur de ceux-ci pour ouvrir et fermer les moyens formant passage, et un packer (20) adjacent audit échantillonneur,
mettre en place ledit packer de sorte qu'un annulus de puits soit défini au-dessus de ce dernier et en dessous de ce dernier,
actionner ledit canon pour perforer ladite formation,
ouvrir ladite vanne d'échantillonneur pour admettre du fluide de formation à partir dudit annulus de puits situé en dessous dudit packer à travers ledit passage jusque dans l'échantillonneur (22),
fermer ladite vanne d'échantillonneur,
mettre hors de prise ledit packer,
retirer ledit outil dudit alésage de puits, et
extraire le fluide dudit échantillonneur, caractérisé en ce que l'entrée met en communication le fluide de formation uniquement vers ledit passage, et ledit passage dirige ledit fluide uniquement vers ledit échantillonneur, un volume prédéterminé de fluide de formation étant admis vers l'échantillonneur, l'échantillonneur étant fermé vers l'intérieur du train d'outil, et l'échantillon est complètement enfermé à l'intérieur de l'échantillonneur pour être enlevé de l'alésage du puits, de telle sorte qu'aucun fluide de formation ne peut entrer à l'intérieur du train d'outil.

11. Procédé selon la revendication 9 ou 10, dans lequel ledit échantillonneur comprend deux ou plus de deux modules (214) formant échantillonneurs individuels qui y sont disposés, et comportant en outre l'étape consistant à remplir ledits modules formant échantillonneurs avec des volumes séparés de fluide de formation.

12. Procédé selon la revendication 9, 10 ou 11, comportant en outre, avant d'ouvrir ladite vanne d'échantillonneur, l'étape consistant à piéger les débris résultant de ladite perforation et la boue de filtration dans une partie de boîtier située en dessous dudit canon.

10. Procédé selon la revendication 9, dans lequel ladite vanne d'échantillonneur est une vanne d'échantillonneur sensible à une pression, ladite étape consistant à ouvrir ladite vanne d'échantillonneur comportant l'abaissement de la pression dans ledit annulus de puits au-dessus dudit packer pour créer une pression différentielle à travers ladite vanne d'échantillonneur, et ladite étape de fermeture de ladite vanne comporte l'élévation de la pression dans ledit annulus de puits situé au-dessus dudit packer et l'abaissement de la pression dans ledit outil pour fournir une pression différentielle inverse à travers ladite vanne d'échantillonneur.
