Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).
Description

The invention concerns liquid (meth)acrylic ester impregnant compositions, their preparation and their use. The sealing of small pores in porous rigid articles by impregnation with such a liquid synthetic resin impregnant and subsequent curing of resin in the pores, is well known. The articles include particularly metal castings and sintered metal parts but also include materials such as wood or inorganic materials such as brick, stone or concrete.

The impregnation of metal castings with resins to seal porosity is a process which is well established. Porosity in castings is invariably inconsistent in size and shape, thus rendering the components unusable due to leakage. This is especially true where they are subjected to pressure. Apart from this well known cause for rejection of castings used in the motor industry there are many other problems caused by porosity including plating failures, "blow out" during stove enamelling, and sites for corrosion, entrapment of organic material and possible bacteria growth.

Generally, porosity can be divided into three types: through porosity, blind porosity and enclosed porosity. Through porosity causes leakage and is the type which founders are primarily concerned. Blind porosity, having one entrance to the surface only, will not produce a leakage but can cause surface finishing problems through absorption of treatment fluids. Enclosed porosity causes no problems unless present in excess where it can cause structure failure. Other similar defects often encountered in the foundry include cold laps, cracks, blow holes, and inclusions all of which are often referred to, incorrectly, as forms of porosity. Frequently examination of a casting rejected for leakage and marked by the inspector as porous, reveals that it actually has a cold lap, crack or a blow hole.

Various methods of sealing porosity employed over the years include plugging, coating with epoxy resin, and welding. All of these techniques are highly labour intensive and therefore expensive, and there is no guarantee that the treatment will be successful.

One known preferred impregnation technique for sealing porous articles comprises immersing the article in liquid impregnant under vacuum conditions in an autoclave, allowing the pressure to rise so forcing the impregnant into the pores, removing the impregnated article, washing the impregnant from the surface and curing the impregnant which remains in the pores. The article is preferably subjected to vacuum conditions before immersion in the liquid impregnant but it is also possible to immerse the article in the impregnant before drawing the vacuum in the autoclave. The washing step is desirable carried out using water and in many cases it will be desirable to include a surfactant either in the water or in the impregnant. The impregnants normally used are based on one or more esters of (meth)acrylic acid, at least some of esters being derived from polyfunctional alcohols in order to provide cross linking on curing. The impregnant will normally contain a free radical-producing curing agent such as a peroxide or azo compound and an inhibitor such as a sterically hindered phenolic compound. It is also desirable to include a small amount of metal chelating agent. Compositions catalysed by peroxy compounds and azo compounds can be heat-cured e.g. by immersing the article in hot water at say 90°C. Anaerobically curing compositions on the other hand require peroxy catalysts.

The impregnant compositions should have a sufficiently low viscosity to permit them to be drawn into the pores of the article (it should be noted in this connection that metal castings tend to have smaller pores than sintered metal articles). On the other hand, too low a viscosity encourages unwanted leaching out of impregnant from the pores during the washing step. Also, of course, water solubility has to be taken into account if an aqueous wash liquid is used. Furthermore, impregnants of low volatility clearly have to be used in order to avoid boiling off under vacuum conditions. A low surface tension liquid impregnant is also desirable since it permits wetting of the metal in the pores and improves adhesion of the cured resin.

The storage and curing properties of the impregnant composition can be appropriately adjusted by varying the proportions of the catalyst and the inhibitor. My U.K. Patent GB-A-1,547,801 describes various compositions which are stable at room temperature and which may be cured at 90°C in a water bath in a period from 3 to 15 minutes. Further compositions of this type are disclosed in European Patent EP-B-14062 of Locite (Ireland) Limited. Anaerobically curing systems are for example described in UK Patent GB-A-1,527,448 of Loclite Corporation. These documents describe examples of impregnant compositions of the type with which the present invention is concerned and give examples of monomers, catalysts and inhibitors together with the proportions in which they may be used.

As further background prior art, it should be mentioned that Japanese Patent Application No. 56-130182 (Kokai No. 58-32612) of Chuo Hatsuumei Kenkyusho K.K. describes an impregnant based on (meth)acrylic esters. A "titanium coupling agent" may be included for lowering the surface tension and improving adhesion to metal, but no examples of such coupling agents are given.
According to a principal aspect of the present invention, there is provided a liquid (meth)acrylic ester impregnant composition comprising a free radical catalyst, an inhibitor and a C₆-C₁₈ alkyl and/or polyfunctional (meth)acrylic ester which has been obtained by transesterification in the presence of an organotitanium catalyst and from which the catalyst residue has not been removed. The composition is preferably room temperature-stable (without aeration) and hot water-curable and the preferred transesterification catalyst is tetra-isopropyl titanate. While impregnants of the invention will normally be sold with the free radical catalyst mixed in, it is envisaged that the catalyst may be supplied in a separate pack for addition by the customer.

According to a second aspect of the invention there is therefore provided a liquid (meth)acrylic ester impregnant composition comprising a hydroxyalkyl (meth)acrylate, a C₆-C₁₈ alkyl (meth)acrylate, a polyfunctional (meth)acrylate, at least one of the C₄-C₁₈ alkyl or polyfunctional (meth)acrylic ester being a (meth)-acrylic ester which has been obtained by transesterification in the presence of an organotitanium catalyst and from which the catalyst residue has not been removed, and an inhibitor.

According to another aspect of the invention, there is provided a process for preparing a liquid (meth)-acrylic ester impregnant composition which includes an inhibitor which process comprises reacting a C₁₋C₃ alkyl (meth)acrylate with a C₆-C₁₈ alcohol in the presence of an organotitanium catalyst to provide a C₄-C₁₈ alkyl (meth)acrylate, and adding a polyfunctional (meth)acrylate and a hydroxyalkyl (meth)acrylate to the reaction product without removal of the organotitanium catalyst.

According to a further aspect of the invention, there is provided a process for preparing a liquid (meth)-acrylic ester impregnant composition which includes an inhibitor, which process comprises reacting a C₁₋C₃ alkyl (meth)acrylate with a polyfunctional alcohol, such as a glycol or a polyalkylene glycol, in the presence of an organotitanium catalyst to provide a polyfunctional (meth)acrylate and adding a C₄-C₁₈ alkyl (meth)acrylate and a hydroxyalkyl (meth)acrylate to the reaction product without removal of the organotitanium catalyst.

The most preferred impregnant compositions with which the invention is concerned include as polyfunctional (meth)acrylate, polyethylene glycol dimethacrylate, triethylene glycol dimethacrylate, trimethyl propane trimethacrylate and tetraethylene glycol dimethacrylate. As explained in U.K. Patent GB-A-1,547,801, it is, however, desirable to include some monofunctional (meth)acrylate because the monofunctional compounds are more stable and less susceptible to anaerobic effects. Furthermore, wholly polyfunctional (meth)acrylate esters tend to shrink on curing to a greater extent than mixtures with monofunctional esters which can lead to leakage problems. Polyfunctional (meth)acrylate ester resins are also more brittle so that a plasticising effect is necessary to give the necessary properties: the plasticising effect may be obtained by incorporating a conventional resin plasticiser such as dioctyl phthalate or it may be obtained by using a monofunctional (meth)acrylate comonomer. Lower i.e. C₁ to C₃ monofunctional (meth)acrylates such as methyl (meth)acrylate tend to be too volatile and C₁₀ to C₁₄ alkyl (meth)acrylates are more preferred. It is also desirable to include a hydrophilic alkyl (meth)acrylate such as hydroxypropyl methacrylate or hydroxyethyl acrylate to facilitate washing and to improve adhesion of the cured resin.

Among suitable monofunctional esters are those having the formula:

\[ CH₂ = CR₁R₂COOR₃ \]

where R₁ is H or CH₃, R₂ is Cₙ H₂ₙ₊₁ or Cₙ H₂ₙOH (where n is 4-18, preferably 4-14, particularly 10-14 and m has similar values except that the minimum value can be as low as 2), CH₂CH₂O(CH₂CH₂O)ₙH or CH₂CH(CH₂)ₙO(CH₂CH₂(CH₃)₀H, where x is 0 to 10 (the units optionally being reversed in the case of propylene glycol). As examples, butyl acrylate, hydroxypropyl acrylate, 2-ethyl-hexyl acrylate, lauryl methacrylate, trimethyl methacrylate and stearyl methacrylate may be cited. Although many monoesters of acrylic and/or methacrylic acid may be employed, the actual choice will be governed on the one hand by avoidance of too high a volatility and on the other by the desirability of a low viscosity. At least sufficient polyfunctional monomer should also be present in order to provide a cross-linked resin on curing.

The proportion of polyfunctional (meth)acrylate ester monomer may vary depending on the degree of solvent and heat resistance expected of the sealed article but is desirably in the range 2-70% of the impregnant and preferably lies in the range 2-40% most preferably 5-25%. The upper limit is determined in part by economic considerations as the polyfunctional esters are more expensive. More important is the fact that monofunctional acrylates or methacrylates appear to be more stable and less susceptible to anaerobic effects than polyfunctional monomers. It is a feature of the preferred process that curing takes place in hot water even in the presence of some dissolved air. Systems which exhibit too great an anaerobic effect can cause difficulties with certain particularly active metal alloys. In extreme cases of anaerobic systems, particularly where a sintered component is involved, a thin film of partially cured resin is already present on
removal from the autoclave and this is difficult to remove by washing and results in dirty products.

Although the preferred impregnants are substantially wholly (meth)acrylate ester (at least as far as the monomers are concerned), other monomers such as diallyl phthalate or esters based on maleates or fumarates may also be included in small quantities, as may non-polymerisable extenders such as phthalate esters e.g. dibutyl phthalate or dioctyl phthalate. Too high a proportion of extender should be avoided as castings in contact with solvents may develop microporosity due to migration of the extender.

It may be convenient to include surfactants (which term includes emulsifying agents, wetting agents and detergents) in the impregnant as an aid to subsequent water washing. The choice of surfactant will be based on the usual principles and will be determined by the actual composition of the impregnant. In general the most useful surfactants will be found amongst those recommended for use with liquids of high polarity rather than those designed for emulsification of paraffinic oils. Although cationic and anionic surfactants can be used, non-ionic surfactants of the ethoxylated and propoxylated alcohol type are preferred, e.g. at 0.1 to 1% concentration if added to the wash water or 1 to 10% if present in the impregnant. Sodium metasilicate at a level of about 1% has been found to be effective in the wash water.

Many catalysts and inhibitors have been found satisfactory for the operation of the preferred impregnation process. The principle governing the choice is that the combination should desirably give rise to an impregnant, a sample of which when placed in a test tube at 90°C should gel in a time of between 1 to 15 minutes and preferably 1.5 to 5 minutes. Typically the quantities may be selected within the range 0.1-15%, preferably 1-5% catalyst and 0.01-2% inhibitor. A wide range of catalysts including benzoil peroxide, methyl ethyl ketone peroxide, various alkyl peresters, cumene hydroperoxide and azo catalysts such as AZBN (azoisobutyronitrile) have been found suitable. A similarly wide selection of inhibitors has been found suitable, including those in common use such as hydroquinone, substituted hydroquinones such as methoxyhydroquinone, p-cresol and m-cresol, and various hindered alkyl phenols such as 2,6-di-tet-butyl p-cresol and 2,5-di-tet-Butyl hydroquinone; methylene blue is also useful. The viscosity of such an impregnant has been found to remain almost constant when the throughput of castings is such that there is a residence time for the impregnant in the autoclave of several weeks.

Various metal ion chelators of the type described in European Patent EP-B14062 may also be included in the impregnant.

The time required for impregnation varies with the type of product. In practice a time of 10 minutes at a vacuum of 2-5 mm of Hg (266-665Pa) has been found sufficient for the majority of commercially available castings. In the case of one small sintered iron component 3 minutes was found sufficient whereas in another instance impregnation of wood was found to require 30 minutes. In no instance was pressure required.

Various methods of conveying the articles through the stages of the process may be used. Generally it is found convenient to pack medium sized castings in baskets constructed of steel mesh. Thus on removal from the impregnant, the basket can be drained over a draining tray and it is advantageous if the angle of tilt of the baskets can be altered to allow more thorough draining.

Immersion of the articles in a water or water plus detergent tank allows impregnant to be worked from the surface within 10 minutes. agitation should be provided to facilitate this process. The use of water as a washing medium is both economical and safer than the use of solvents. One of the greatest deterrents to widespread use of impregnation equipment is connected with effluent disposal problems. It is a feature of the process that apart from the methods available to break emulsions which will be familiar to those accustomed to dealing with the disposal of cutting oils, a simpler method has been found possible. Thus when the level of emulsified impregnant has built up to a concentration of 1-5%, the wash liquors may be pumped to a separate tank capable of raising the temperature above 80°C. For example after only 2 minutes at 100°C, the emulsion suddenly curdles and on cooling, the nearly clear supernatant liquid may be drained into the sewer leaving a damp granular solid which, being a polymer, may be disposed of as an inoffensive almost odourless solid waste. At 90°C curdling may take 20 minutes.

Following rinsing, the articles are drained for a few moments and then transferred to the curing tank.

The use of hot water to cure the impregnant offers several advantages over other alternative procedures. The hot water acts as an additional washing medium to remove traces of partially emulsified impregnant from the surface of the casting, particularly from the inside of tapped holes. It is commonly found that processes employing oven curing result in dirty castings and this imposes limitations on the type of casting which may be sealed by this method. Another advantage in curing in hot water arises from the fact that, as is well known, many monomers of which methacrylates and styrene are examples are inhibited by air and consequently satisfactory curing of resin takes place even at the surface of the pores where the water acts as a barrier. With low viscosity impregnants there is obviously a risk that hot oils or solvents might leach impregnant from the larger pores before curing could take place. The use of hot water has been found to be
satisfactory in this respect. Thus plating processes, to be successful, require that the level of resin in the pores should be such that entrapment of plating fluids beneath the metal plating is avoided. Satisfactory plating of sintered parts has been shown to be possible using the process of the invention. It is also convenient that on removal of castings from the hot water almost immediate evaporation of water occurs and when cool, the castings are immediately ready for pressure testing or any further engineering operations.

The temperature of the water in the curing tank should be such that an adequate margin exists for curing the monomer in the time allotted for immersion. In a preferred embodiment of the invention the impregnant will have a curing time at 90°C of 10-15 minutes. It will be clear that at temperatures above 95°C the presence of steam will become increasingly inconvenient. Below 70°C, the required immersion time to ensure satisfactory curing lengthens considerably unless the catalyst/inhibitor balance is altered. However this implies that the stability of the impregnant in the autoclave is reduced. It is therefore desirable that the curing temperature should be in the range 80°C - 95°C and preferably close to 90°C.

A feature of the preferred process is therefore that although several stages are involved, none require longer than 10 minutes and this allows a sequence of baskets containing castings to be processed in an unusually compact design of plant.

Although impregnation is the preferred method of carrying out the process, pressure impregnation could be used or indeed the article could simply be dipped into the impregnant.

Higher alkyl (meth)acrylates and polyfunctional (meth)acrylates are normally manufactured in practice by a transesterification reaction, between methyl (meth)acrylate, a suitable higher alcohol and a catalyst in a suitable proportion for effecting the reaction within a suitable time at a convenient temperature. As mentioned above, the higher alkyl (meth)acrylates useful for the present invention are C₄-C₁₈ alkyl, preferably C₆-C₁₄ alkyl and particularly C₁₀-C₁₄ alkyl.

The higher alcohol reacts with the methyl (meth)acrylate at temperatures around 100°C (50-150°C) to produce higher alkyl (meth)acrylate and methanol, the latter being removed from the reaction zone in order to drive the reaction to completion. The transesterification reaction will often be carried out using a stoichiometric excess of methyl (meth)acrylate to ensure complete conversion of higher alcohol to ester. It is also common practice to include a hydrocarbon solvent such as cyclohexane or benzene in the reaction mixture to facilitate the separation and removal of the by-product methanol from the methyl (meth)acrylate reactant via an azeotropic distillation. Inhibitors, such as substituted phenols or other inhibitors, will also be included to prevent premature polymerisation of the monomers during the reaction.

Upon completion of the reaction, indicated by cessation of methanol evolution, it has, up till now, been the practice to purify the products prior to use first by removing any volatile materials such as excess methyl (meth)acrylate by distillation under vacuum and then to vacuum distil the product itself. Should the product have such a high boiling point as to render distillation difficult or impossible without polymerisation the product would be purified by treatment in the liquid state to adsorb and remove catalyst residues or coloured bodies etc.

Treatment can also take a form whereby catalyst residues are reacted, e.g. by alkaline hydrolysis, to render them insoluble so that they precipitate from the product and can be removed by a suitable means such as filtration, centrifugation, or adsorption onto charcoal prior to filtration. Such purification stages are both time consuming and lead to yield losses and therefore add significantly to the cost of manufacturing higher alkyl (meth)acrylates and polyfunctional (meth)acrylates.

As mentioned above, we have now found, according to the invention that it is not necessary to remove the catalyst, and that the C₄-C₁₈ alkyl or polyfunctional (meth)acrylate can be used in the condition that appertains after reaction and removal of by-products such as excess methyl (meth)acrylate and methanol.

The use of C₄-C₁₈ alkyl and polyfunctional (meth)acrylates without removal of the catalyst in an impregnant composition lowers the surface tension of the composition leading to improved wetting and adhesion. Cured impregnants also show greater stability when subjected to elevated temperature conditions such as 200°C. The omission of the step of removing the catalyst also reduces the cost of producing the impregnant composition.

The catalyst normally used for the alcoholysis transesterification process is an organometallic titanium compound, particularly a tetra lower alkyl orthotitanate such as tetra isopropyl titanate or tetra-n-butyl titanate, or the titanate of the relevant higher alcohol could also be used. Titanates are effective transesterification catalysts as they do not promote side reactions and only require moderate temperatures.

Thus the liquid (meth)acrylate ester impregnant compositions may be prepared by a process which comprises reacting a lower alkyl (meth)acrylate with a C₄-C₁₈ alcohol and a polyfunctional alcohol or a mixture thereof, either alone or together, in the presence of an organo titanium catalyst to provide a mixed (meth)acrylate ester composition and adding one or more other desirable (meth)acrylate esters such as
hydroxyalkyl (meth)acrylates, polyalkylene glycol mono(meth)acrylates, (meth)acrylate containing oligomers etc.

In this connection, it has been found that adding a similar amount of titanium catalyst to an impregnant composition made from purified monomers from which the original catalyst has been removed is generally less satisfactory e.g. because the added titanium compound tends to precipitate out. It is now believed that the catalyst residue normally removed from the transesterification product is the tetra-alkoxide derived from the higher alkyl group or the polyfunctional alkyl group and not the original catalyst (which is more susceptible to hydrolysis). It is also believed that hydroxyalkyl (meth)acrylate esters may play a part in binding the catalyst residue.

Our experiments have shown that it is desirable for the impregnant to contain at least 50, preferably 100-1000, ppm Ti derived from the transesterification catalyst.

Impregnants of the invention preferably comprise a hydroxyalkyl (meth)acrylate, a higher (C₄-C₁₈) alkyl (meth)acrylate and a polyfunctional (meth)acrylate generally in the proportions 25-65% hydroxyalkyl (meth)-acrylate, 15-70% higher (C₄-C₁₈) alkyl (meth)acrylate and 5-20% polyfunctional (meth)acrylate. Desirably the hydroxyalkyl (meth)acrylate is hydroxypropyl methacrylate, the higher alkyl (meth)acrylate is lauryl or tridecyl methacrylate and the polyfunctional (meth)acrylate is triethylene glycol dimethacrylate or trimethylol-propane trimethacrylate and the higher alkyl (meth)acrylate has 10-14 carbon atoms in the alkyl group.

The invention also extends to a vacuum impregnation process in which a porous rigid article is vacuum impregnated with a composition of the invention, excess impregnant is removed by washing and the impregnant in the pores is cured by heating.

EXAMPLES

A range of impregnant compositions (also referred to in the art as sealants) was prepared using monomers prepared and purified to a normal commercial quality and also monomers according to this invention in which the tetra-isopropyl titanate esterification catalyst was allowed to remain in the monomer. These impregnants were subjected to a series of evaluation tests as detailed below.

SEALING PERFORMANCE

Annular sintered iron test rings of 20% pore volume and dimensions 25mm outside diameter, 14mm inside diameter, and 14mm height were impregnated using a wet vacuum technique. This consisted of immersing the rings in the impregnant and subjecting them to vacuum of 5 mbar for 10 minutes to remove air from the porosity, and releasing the vacuum to atmospheric pressure to fill the pores with impregnant.

The rings were removed from the impregnant, allowed to drain, washed with water and the impregnant polymerised in the pores by immersing the rings in hot water at 90°C for 10 minutes. The rings were pressure tested under water with air at 90 psi (621 kPa) pressure and assessed for leaks on a 0-5 scale with 0 signifying no leakage and 5 a level of leakage at which correspondingly impregnated castings (as opposed to test rings) might not be 100% sealed.

THERMAL STABILITY

Small samples of impregnant were polymerised in 3mm diameter test-tubes for 30 minutes at 90°C. The samples were removed from the test-tubes and the percentage loss in weight determined after 1 hour and 24 hours, at 150°C and 200°C. The percentage loss in impregnant weight was also determined under the same conditions but using impregnated sintered metal test rings as described above.

GEL TIME

A 5ml sample of impregnant was heated in a test-tube in a water bath at 90°C. The time taken for polymerisation to proceed to a point where the tube and its contents could be lifted from the water bath on the end of a piece of wire immersed in the impregnant was determined.

The following three impregnant formulations were prepared with the amounts being given in parts by weight.
Results of the various tests are given in the table below:

The results quoted are the average of duplicate tests and they clearly indicate the superior sealing performance and improved thermal stability of the impregnants of the invention.

The following five impregnant formulations were prepared with the amounts being given in parts by weight.
Hydroxypropyl methacrylate  25  25  25  25  25
Tridecyl methacrylate  (purified)  70  52.5  35  17.5  --
Tridecyl methacrylate  (including catalyst residue 150 ppm as Ti)  --  17.5  35  52.5  70
Trimethylolpropane trimeth acrylate  5  5  5  5  5
Azobisisobutyronitrile  0.4  0.4  0.4  0.4  0.4
Inhibitor (sterically hindered substituted phenol)  0.15  0.15  0.15  0.15  0.15
Residual Ti in ppm  0  26  52.5  79  105

% Wt loss at 200°C
Test piece 1 hour  6.3  2.8  3.2  3.4  3.0
24 hours  63.4  43.0  16.3  17.6  16.3
Test ring 1 hour  4.9  6.5  7.1  6.4  4.1
24 hours  29.6  29.5  27.5  24.2  25.5

Test ring sealing rating
After polymerisation  0  0  0  0  0
After 1 hour at 200°C  1  0  0  0  0
After 24 hours at 200°C  1  2  0  0  0

It will be apparent from the Formulations 4-8 that good sealing is achieved and this is primarily attributable to the high proportion of tridecyl methacrylate which gives flexibility to the cured product. The 5% polyfunctional methacrylate is in fact sufficient to make the resin thermosetting. On the other hand the presence of Ti increases thermal stability markedly.

Claims

1. A liquid (meth)acrylic ester impregnant composition comprising a free radical catalyst, an inhibitor, and a higher (C₄-C₈) alkyl (meth)acrylic ester and/or polyfunctional (meth)acrylic ester which has been obtained by transesterification in the presence of an organotitanium catalyst and from which the catalyst residue has not been removed.

2. A composition according to claim 1 which is room temperature-stable and hot water-curable.

3. A composition according to claim 1, 2 or 3 wherein said organotitanium catalyst comprises an alkyl titanate.
4. A composition according to claim 3, wherein the alkyl titanate is tetra-isopropyl titanate or tetra-n-butyl titanate.

5. A composition according to any preceding claim which contains 50-1000 ppm of Ti.

6. A composition according to any preceding claim, which comprises a hydroxyalkyl (meth)acrylate, a higher (C₂-C₁₈) alkyl (meth)acrylate and a polyfunctional (meth)acrylate.

7. A composition according to claim 6, wherein the monomers are in the proportions 25-65% hydroxyalkyl (meth)acrylate, 15-70% higher (C₄-C₁₈) alkyl (meth)acrylate and 5-20% polyfunctional (meth)acrylate.

8. A composition according to claim 6 or 7, wherein the hydroxyalkyl (meth)acrylate is hydroxypropyl methacrylate, the higher alkyl (meth)acrylate is lauryl or tridecyl methacrylate and the polyfunctional (meth)acrylate is triethylene glycol dimethacrylate or trimethylol-propane trimethacrylate.

9. A composition according to any one of claims 1-7 wherein the higher alkyl (meth)acrylate has 10-14 carbon atoms in the alkyl group.

10. A vacuum impregnation process in which a porous rigid article is vacuum impregnated with a composition according to any preceding claim, excess impregnant is removed by washing and the impregnant in the pores is cored by heating.

11. A process for preparing a liquid (meth)acrylic ester impregnant composition which includes an inhibitor, which process comprises reacting a lower (C₁-C₃) alkyl (meth)acrylate with a higher (C₄-C₁₈) alcohol in the presence of an organotitanium catalyst to provide a higher (C₄-C₁₈) alkyl (meth)acrylate, and adding a polyfunctional (meth)acrylate and a hydroxyalkyl (meth)acrylate to the reaction product without removal of the organotitanium catalyst.

12. A process for preparing a liquid (meth)acrylate ester impregnant composition which includes an inhibitor, which process comprises reacting a lower (C₁-C₃) alkyl (meth)acrylate with a polyfunctional alcohol such as a glycol or polyalkylene glycol in the presence of an organotitanium catalyst to provide a polyfunctional (meth)acrylate and adding a higher (C₄-C₁₈) alkyl (meth)acrylate and a hydroxyalkyl (meth)acrylate to the reaction product without removal of the organotitanium catalyst.

13. A liquid (meth)acrylic ester impregnant composition comprising a hydroxyalkyl (meth)acrylate, a higher (C₄-C₁₈) alkyl (meth)acrylate, a polyfunctional (meth)acrylate, at least one of the higher (C₄-C₁₈) alkyl or polyfunctional (meth)acrylic ester being a (meth)acrylic ester which has been obtained by transesterification in the presence of an organotitanium catalyst and from which the catalyst residue has not been removed, and an inhibitor.

Patentansprüche

1. Flüssige (Meth)acrylsäureester-Imprägniermittelzusammensetzung mit einem freien Radikale bildenden Katalysator, einem Inhibitor und einem höheren (C₄-C₁₈)-Alkyl-(meth)acrylsäureester und/oder polyfunktionellen (Meth)acrylsäureester, welcher durch Umesterung in Gegenwart eines titanorganischen Katalysators erhalten wurde und aus welchem der Katalysatorrest nicht entfernt wurde.

2. Zusammensetzung nach Anspruch 1, welche bei Raumtemperatur beständig und mit heißem Wasser härtbar ist.

3. Zusammensetzung nach Anspruch 1, 2 oder 3, in welcher der titanorganische Katalysator ein Alkyltitanat umfaßt.

4. Zusammensetzung nach Anspruch 3, bei der das Alkyltitanat Tetraisopropyltitanat oder Tetra-n-butyltitanat ist.

5. Zusammensetzung nach einem der vorausgehenden Ansprüche, welche 50 bis 1000 ppm Ti enthält.
6. Zusammensetzung nach einem der vorausgehenden Ansprüche, welche ein Hydroxyalkyl-(meth)acrylat, ein höheres (C₄-C₁₈)-Alkyl-(meth)acrylat und ein polyfunktionelles (Meth)acrylat umfaßt.

7. Zusammensetzung nach Anspruch 6, worin die Monomeren in den Mengenverhältnissen 25 bis 65 % Hydroxyalkyl-(meth)acrylat, 15 bis 70 % höheres (C₄-C₁₈)-Alkyl-(meth)acrylat und 5 bis 20% polyfunktionelles (Meth)acrylat vorliegen.

8. Zusammensetzung nach Anspruch 6 oder 7, in der das Hydroxyalkyl-(meth)acrylat Hydroxypropylmethacrylat ist, das höhere Alkyl-(meth)acrylat Lauryl- oder Tridecylmethacrylat ist und das polyfunktionelle (Meth)acrylat Triethylen glycoldimethacrylat oder Trimethylolpropantrimethacrylat ist.

9. Zusammensetzung nach einem der Ansprüche 1 bis 7, in der das höhere Alkyl-(meth)acrylat 10 bis 14 Kohlenstoffatome in der Alkylgruppe hat.

11. Verfahren zur Herstellung einer flüssigen (Meth)acrylsäureester-Imprägniermittelzusammensetzung, die einen Inhibitor enthält, indem man ein niedermolekulares (C₁-C₆)-Alkyl-(meth)acrylat mit einem höheren (C₄-C₁₈)-Alkyl-(meth)acrylat in Gegenwart eines zinnorganischen Katalysators umsetzt, um ein höheres (C₄-C₁₈)-Alkyl-(meth)acrylat zu bekommen, und ein polyfunktionelles (Meth)acrylat und ein Hydroxyalkyl-(meth)acrylat zu dem Reaktionsprodukt ohne Entfernung des titanorganischen Katalysators zusetzt.

12. Verfahren zur Herstellung einer flüssigen (Meth)acrylatester-Imprägniermittelzusammensetzung, die einen Inhibitor enthält, indem man ein niedermolekulares (C₁-C₆)-Alkyl-(meth)acrylat mit einem polyfunktionellen Alkohol, wie einem Glycol oder Polyalkylen glycol, in Gegenwart eines titanorganischen Katalysators umsetzt, um ein polyfunktionelles (Meth)acrylat zu bekommen, und ein höheres (C₄-C₁₈)-Alkyl-(meth)acrylat und ein Hydroxyalkyl-(meth)acrylat zu dem Reaktionsprodukt ohne Entfernung des titanorganischen Katalysators zusetzt.

13. Flüssige (Meth)acrylsäureester-Imprägniermittelzusammensetzung mit einem Hydroxyalkyl-(meth)acrylat, einem höheren (C₄-C₁₈)-Alkyl-(meth)acrylat und einem polyfunktionellen (Meth)acrylat, wobei wenigstens eines des höheren (C₄-C₁₈)-Alkyl- oder polyfunktionellen (Meth)acryl sû reesters ein (Meth)acrylsäureester ist, welcher durch Umesterung in Gegenwart eines titanorganischen Katalysators erhalten wurde und aus welchem der Katalysatorrest nicht entfernt wurde, und mit einem Inhibitor.

Revidications

1. Composition liquide d’imprégnation à base d’ester (méth)acrylique comprenant un catalyseur produtc-
teur de radicaux libres, un inhibitoe et un ester (méth)acrylique d’alkyle supérieur en (C₄-C₁₈) et/ou un ester (méth)acrylique polyfioncnel qui a été obtenu par transestérification en presence d’un cataly-
seur organo-titane et duquel le catalyseur résiduel n’a pas été éliminé.

2. Composition selon la revendication 1, caractérisée en ce qu’elle est stable à la température ambiante et durcissable par l’eau chaude.

3. Composition selon l’une des revendications 1 ou 2, caractérisée en ce que ledit catalyseur organo-
titane comprend un titane d’alkyle.

4. Composition selon la revendication 3, caractérisée en ce que le titane d’alkyle est le titane de tétraisopropyle ou le titane de tétra-n-butyle.

5. Composition selon l’une des revendications précédentes, caractérisée en ce qu’elle contient 50-1 000 ppm de Ti.
6. Composition selon l'une des revendications précédentes, caractérisée en ce qu'elle comprend un (méth) acrylate d'hydroxyalkyle, un (méth)acrylate d'alkyle supérieure en (C₄-C₁₈) et un (méth)acrylate polyfonctionnel.

7. Composition selon la revendication 6, caractérisée en ce que les monomères sont présents dans des proportions de 25 - 85 % de (méth)acrylate d'hydroxyalkyle, 15 - 70 % de (méth)acrylate supérieur en (C₄-C₁₈) et 5 - 20 % de (méth)acrylate polyfonctionnel.

8. Composition selon l'une des revendications 6 ou 7, caractérisée en ce que le (méth)acrylate d'hydroxyalkyle est le méthacrylate d'hydroxypropyle, le (méth)acrylate d'alkyle supérieur est le méthacrylate de lauryle ou de tridécyle, et le (méth)acrylate polyfonctionnel est le diméthacrylate de triéthylène glycol ou le triméthacrylate de triméthylol-propane.

9. Composition selon l'une des revendications 1 à 7, caractérisée en ce que le méthacrylate d'acryle supérieur possède 10 à 14 atomes de carbone dans le groupe alkyle.

10. Procédé d'imprégnation sous vide, caractérisé en ce qu'un article poreux est imprégné sous vide avec une composition selon l'une des revendications précédentes, l'agent d'imprégnation en excès est éliminé par lavage, et l'agent d'imprégnation se trouvant dans les pores est durci par chauffage.

11. Procédé de préparation d'une composition liquide d'imprégnation à base d'ester (méth)acrylique, caractérisé en ce qu'il comprend la réaction d'un (méth)acrylate d'alkyle inférieur en (C₄ à C₂) avec un alcool supérieur en (C₄ à C₁₈) en présence d'un catalyseur organo-titane pour produire un (méth)-acrylate d'alkyle supérieur en (C₄ à C₁₈), et l'addition d'un (méth)acrylate polyfonctionnel et d'un (méth)acrylate d'hydroxyalkyle au produit réactionnel sans élimination du catalyseur organo-titane.

12. Procédé de préparation d'une composition liquide d'imprégnation à base d'ester (méth)acrylique, caractérisé en ce qu'il comprend la réaction d'un (méth)acrylate d'alkyle inférieur en (C₄ à C₂) avec un alcool polyfonctionnel tel qu'un glycol ou un polyalyle glycol en présence d'un catalyseur organo-titane pour produire un (méth)acrylate polyfonctionnel et l'addition d'un (méth)acrylate d'alkyle supérieur en (C₄ à C₁₈) d'un (méth)acrylate d'hydroxyalkyle au produit réactionnel sans élimination du catalyseur organo-titane.

13. Composition liquide d'imprégnation à base d'ester (méth)acrylique, caractérisée en ce qu'elle comprend un (méth)acrylate d'hydroxyalkyle, un (méth)acrylate d'alkyle supérieur en (C₄ à C₁₈) et un (méth)acrylate polyfonctionnel, au moins l'un parmi le (méth)acrylate d'alkyle supérieur en (C₄ à C₁₈) ou l'ester (méth)acrylique polyfonctionnel étant un ester (méth)acrylique qui a été obtenu par transésterification en présence d'un catalyseur organo-titane et duquel le catalyseur résiduel n'a pas été éliminé, et un inhibiteur.
