Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
BACKGROUND OF THE INVENTION

This invention relates to a method and an apparatus for automatically extracting a weld defect image based on a radiographic transmission test, particularly for detecting defects at welding portions of pipes or the like in power plant facilities.

Large machines, plant facilities, etc. are made up of the organic linkage of complex mechanical devices, which involve many joint portions based on welding. These welding portions are often important sections of the facilities. Welding portions are crucial not only for the retention of the inherent function of the machine, plant facility, etc., but also for the security of the machine and facility and of the peripheral environment. Accordingly, these joint portions are very crucial points of construction and also at the maintenance activity during the operation.

Particularly, such large-scale facilities as power plants and transformer stations, which are operated under intense requirement of security because of their public role, have their periodic and extra maintenance activities, including part replacement, inspection and tuning, carried out strictly under the raw and regulation of electric facilities. For the inspection of internal defects which cannot be done in a visual manner or by means of a surface inspection device, there is stated such a nondestructive inspection method as the X-ray transmission test in the JIS-standard and other regulation. The regulations also cover the threshold of judgement of a weld defect based on the radiographic test.

However, extremely high proficiency is required of the inspector to make a visual judgement based on his experience of the image of a weld defect provided by radiography, and yet the result of judgement is poor in reliability.

The visual inspection and judgement by a skilled inspector rely on the threshold of judgement which can differ depending on each person and can also vary due to the tiredness of vision and psychological pressure, resulting in the difficulty of stable and objective judgement.

Unless a definite judgement of inspection of weld defect is made with high reliability, a further step of maintenance activity cannot be taken, and this situation can impose a serious adverse impact on the operation of the facility in its rated ability and also on the safety of the facility.

Therefore, it is very important for a power plant enterprise to indirectly discriminate the type of weld defect based on the radiography.

There are proposed means of automatic defect extraction in which a welded joint of a pipe or the like is imaged on a radiographic film and the developed image is introduced to a computer so that it is rendered a statistic process and the like and the result of process is used for the judgement by the inspector.

An example of defect extraction method is to categorize defects through the emphasis of a defect image by selective application of computational operations, the binary conversion of the emphasized image using a certain threshold, and the determination based on the density of image. This method will be called "the first method" hereinafter.

Another method publicized is based on the spacial frequency of the density distribution normal to the welding line, in which spectral components of radiographic image is fed through a band-pass filter thereby to extract the discontinuity at a defective portion and the filter output is subjected to the binary conversion based on a certain threshold thereby to make a judgement of weld defect. This method will be called "the second method" hereinafter.

A further method deals with a signal which is produced by scanning the joint in the direction normal to the welding line and the difference between the signal and its quadratic approximation is subjected to a high-frequency filtering process thereby to emphasize the radiographic image to be subjected to the maximizining process. This method will be called "the third method" hereinafter.

A further method developed and publicized makes a quadratic curve approximation of the brightness distribution of the radiographic image taken in the direction normal to the welding line and the approximated curve is subtracted from the original curve thereby to produce an emphasized differential image, and the image is rendered the binary conversion based on the threshold value derived from the density difference, with the image being modified to clarify the boundary of binary image regions. This method will be called "the fourth method" hereinafter.

In order to infer the type of a weld defect from a radiographic image, a method is proposed for deterministically classifying the type of the weld defect by specifying the existing range of feature values for each defect type, on the basis of feature values of the shape of the defect image obtained by the image processing of the radiography. Also, a method for inferring the type of the weld defect from the statistic distribution of the feature values by using probability. These methods will be called "the fifth method" hereinafter. Examples of this inspection system based on the Bayes' law are described in the proceeding of the fourth industrial image sensing technology symposium, pp. 51-56, entitled "WELD INSPECTION EXPERT SYSTEM WITH IMAGE PROCESSING ENVIRONMENT" by Koshimizu, et al, and in publication: Transaction of JWRI, Vol. 11, No. 2, 1982, pp. 123-132, entitled "Automatic Recognition of Weld Defects in Radiographic Test (Report 1)", by Inoue et al.

However, these conventional methods of extracting a weld defect by the inspector, although each having its inherent advantage, are lacking in the practicability as follows.
The first method involves the difficulty in selecting the operation, i.e. the selection of an operation is not possible unless the image of defect is known in advance. Since the value of pixel of the emphasized image does not have a direct physical meaning, it unfavorably necessitates the threshold setting based on try-and-error. The method suffers from high possibility of distortion of an emphasized defect image used for the judgement of defect. Despite the fact that the extracted defect image can possibly include an irrelevant indication signal, the method lacks in the processing scheme for eliminating that signal, resulting possibly in the over sensitivity of defect detection.

The second method is capable of extracting such a volumetric weld defect as a blow hole, but it suffers from extracting a defect image with a small density difference such as that of lack of fusion. Since the image of defect is discriminated based solely on the extracted density difference, the result of detection is not consistent with that of an experienced inspector having high sensitivity of detection. Therefore, it lacks in the practicality as an extraction method, and has a drawback of difficult determination of the threshold value.

The third method is deficient in that the image of defect cannot be emphasized due to a small density difference for a planar weld defect such as a lack of fusion, as in the previous method. Although the method renders the sharpness of image, it cannot eliminate the density variation at the residual weld portion, and it suffers in the inability of defect image extraction with a single threshold value. The third method by itself is not intended for the automatic extraction of a defect image.

The fourth method is incapable of extracting a defect image with a small density difference such as that of lack of fusion. Due to its defect image extraction based solely on the density difference among pixels of emphasized image, the sensitivity of detection can differ from that of an experienced inspector. Consequently, it suffers from poor reliability and from a determination of the defect shape being inconsistent with the result provided by the inspector because its modification process is based solely on the binary-converted image.

The fifth method of the inspection judgement systems offered by Kashimizu et al and Incue et al involves the following problems. The inspection system offered by Kashimizu et al is a determinative method based on the logical sequence, and this method categorized to be an algorithm process scheme suffers from the addition of a new judgement rule and logical treatment. Although this method is advantageous in the logical processing and metrical data processing by using graphical data of the weld defect portion and positions of density around the defective portion, the knowledge of an experienced inspector cannot be introduced or added to the expert system. The system offered by Incue et al uses the Bayes' law, and it requires complete data collection. For example, the system needs nine feature values of defect, and it does not allow the merging with the expert system.

SUMMARY OF THE INVENTION

An object of the invention is to provide a method and an apparatus for automatically extracting a weld defect image based on a radiographic transmission test promptly and accurately from the film image of radiography of a welded portion.

The object is solved according to the features of the independent claims. The dependent claims show advantageous embodiments and further development of the invention.

A radiographic test is conducted for a welded portion of a pipe in a power plant or the like thereby to produce an image of welded portion on a radiographic film or introduce the transmitted radiation rays directly through an image intensifier. A frame of picture including an image of weld defect is introduced to a computer, in which noises are removed, an inspection area is trimmed, and the welding line portion is extracted for preprocessing. Volumetric defects of type 1 and planar defects of type 2 are rendered specific emphasizing processes. After the statistic process, the extraction process is conducted thereby to discriminate a type 1 defect or type 2 defect. Modification is conducted based on the statistic value for the pixel value at the end and peripheral portions of the welding line in the defect-emphasized image of the welding line so that the value is adjusted to be correspondent to the sensitivity of detection implemented by the inspector, thereby making the result of extraction of the defective portion consistent with that of an experienced inspector. Pixel values of the modified, emphasized image are assumed to be in the normal distribution, so that the level of an abnormal image including a defect image can be defined in terms of the standard deviation and the threshold value for the extraction of defective portion can be set easily. The knowledge of an experienced inspector for detecting an irrelevant indication is prepared as a database, and the feature value of defect related to the density and shape measured from the extracted defect candidate is compared with the database so as to remove irrelevant indication images thereby to avoid over-sensitive detection of defect images. Consequently, the ultimate result of judgement of defect is consistent with that of an experienced inspector.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a brief flowchart of the overall processing based on the first embodiment of this invention;
Fig. 2 is a plan view showing by model the sampling area for the modification of pixel value of a differential image;
Figs. 3 and 4 are histograms of the number of pixels of certain pixel values at portions a and b in Fig. 2; Figs. 5a and 5b are plan views showing by model the window of filtering for the emphasizing process for the type 2 defect image; Fig. 6 is a plan view showing by model a defect candidate image before the application of the irrelevant indication removal rule after the extraction of the emphasized image; Fig. 7 is a plan view showing by model th defect candidate image after the application of the irrelevant indication removal rule.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Initially, the emphasizing and extraction processes intended for the accurate and efficient judgement of a candidate defect image implemented by the inspector based on the first embodiment of this invention will be explained on the flowchart of Fig. 1. First, a radiographic test using the X rays or the like is conducted for a certain welded portion of a pipe joint or the like in a power plant facility thereby to form an original image 1 of the welded portion on a radiographic film. The original image on the film is picked up with an ITV camera and introduced to a certain computer, by which noises in the video signal are eliminated. The reason for the removal of noises is the possible degradation of the picture quality due to noises at the introduction of the film image into the computer through the ITV camera. One of noise removal means, known as "median filter", is used. This method is to arrange small "window" areas around each point of the image and replace the point with the median of brightness of these windows. This process prevents the image from being faint due to the noise removal and enables the removal of small data variation and impulse noises in the image without a substantial loss of critical information in the peripheral section. The film image covers, in addition to the welded portion, the base metal and its exterior with the provision of a transmission meter and tone meter thereby to ensure the picture quality. The image includes a mark of literal or numeric character for the identification of the film, and this image can impose a significant influence on the statistic value of brightness distribution of the image, resulting possibly in the failure of emphasis of the defective portion. On this account, this embodiment uses means of sampling an object area by defining the area up to such images as the above-mentioned meters and marks in the vertical direction of the welding line. In this manner, the object area of judgement on the image is sampled (3) and the welding line portion is extracted (4).

A weld defect exists in the region of welding line, and conceivably there is a correlation between the frequency of occurrence of defects of one type and the position on the welding line. Accordingly, the extraction of the welding line region is very important. An image is divided horizontally into divisions with a proper width, and a binary threshold value is determined automatically based on the least square reference for each divided width. Next, the coordinates of the central point in each column of binary image is evaluated thereby to determine the center line of the welding line region by application of the method of least squares.

Emphasized extraction of a defect image having a small density difference, such as a lack of fusion, cannot be done through the sole emphasized extraction for a volumetric defect image of a weld defect portion in the image. Therefore, to deal with this matter, emphasized extraction for a defect image of type 1, i.e., such a volumetric defect image having a relatively strong contrast and having a thickness in the direction of irradiation of the radiation rays, such as the X rays, as a blow hole and slag inclusion, and a procedure based on the emphasized extraction for a defect image of type 2, i.e., such a planar (linear on the film image) defect image having a relatively weak contrast along the welding line as a lack of fusion are conducted at the same time.

The emphasized extraction for a defect image of type 1 is to have a quadratic curve approximation in the direction normal to the welding line thereby to approximate the influence of the brightness of the welding residual portion. Next, the differential process 5 for subtracting the original image from the image with the approximated brightness of the residual portion is conducted.

By this operation, only a change in brightness due to the influence of the defective portion will emerge. By using the fact that the change of brightness in the residual portion is gradual as compared with the change of defect such as a blow hole, a quadratic curve based on the method of least squares is applied to the original image to have a brightness variation, and the differential image is made as an image, with its contrast of defect being emphasized by subtracting the image with the approximated residual portion from the original image. This differential image has a uniform brightness of the background section as an emphasized image, and is displayed as an image with a dark defective portion, and it allows even an unskilled inspector to determine the defective position easily.

Next, the modification of pixel value of the differential image is conducted (process 6 in Fig. 1). The reason is that the central portion and peripheral portion of the welding line are different in brightness even for the same defect and thus an inspector has different sensitivities for brightness. In the case of the visual inspection by the inspector, a psychological adjustment of sensitivity is predicated to take place so that the central portion and peripheral portion of the welding line are sensed in the same brightness. According to this invention, a statistic value of the brightness of the
differential image is taken thereby to implement the process equivalent to the inspector's behavior so that the central portion and peripheral portion have equal sensitivity of brightness in terms of the degree of variance, and the same result as of the inspector's inspection is realized.

Specifically, the range of object for evaluating the statistic value of the overall image is confined to the interior of the welding line 20 as shown in Fig. 2, so that the statistic value which is unrelated to the sampling area can be evaluated without the influence of the base metal. Two regions X and Y of Fig. 2 are set so that the statistic value in the range is made controllable as a parameter of image processing.

When the statistic value of pixel value of X and Y of the differential image is taken, it is known that the standard deviation $\sigma$ is larger at the central bright portion of the welding line and is smaller at the darker boundary portion next to the base metal. Namely, histograms of the number of pixels on the ordinate versus the pixel values on the abscissa for regions of X and Y in Fig. 2 are shown in Figs. 3 and 4. In the differential image, the influence of the brightness change at the residual portion is removed in advance and therefore when it is assumed that there is no defect on the welding line and particle noises distribute evenly on the film, the sensitivity of vision is predicated to be adjusted automatically by the inspector in identifying a defect so that the brightness change of the differential image is identified to some extent.

A certain logarithmic conversion for the brightness is conducted with the intention of conversion of the pixel value to the value which is proportional to the magnitude of human's visual sensitivity. The modified pixel value of defect image is predicated to have been converted to a value which corresponds to the sensitivity of psychological sense of the inspector. Based on this fact, for the modified image, the mean value and standard deviation are evaluated for the statistic value of the brightness distribution of the overall image thereby to determine the threshold value by calculating the mean value of brightness subtracted by the standard deviation multiplied by a (where a is a parameter), and pixels having brightness smaller than or equal to the threshold value are extracted as candidates of defect (process 9 in Fig. 1). A region extracted based on this threshold value can only be an extremely dark portion of the image in some case, and the region is further shaped by expanding the region so that pixels with value of brightness smaller than or equal to the threshold value plus standard deviation divided by b (where b is a parameter) in the peripheral portion of the extraction region are included. The result of extraction in this manner is virtually identical to the result of extraction implemented by the inspector.

For the automatic extraction of candidate defects, if it is necessary to have the strict measurement of the defect shape on a test film with small variation of bead in the residual portion, the quadratic approximation for the change of brightness in the residual portion is implemented not only in the direction normal to the welding line, but also in the direction of welding line, as shown in process 7 in Fig. 1. By implementing the modification of pixel value of differential image (process of Fig. 1) equally to the modification of pixel value for the differential image in the direction normal to the welding line, the results of extraction from these two approximated images are merged as a logical sum of the binary images thereby to extract the region of candidate defect (process of Fig. 1).

By doing in this manner, it is possible to extract a defect image of type 1 accurately without the failure of detection. Images extracted automatically in this manner include an irrelevant indication, which is not an inherent defect image or a defect other than a candidate defect, but is an irrelevant indication caused by a dark shadow or noise in contrast to a portion of sharp variation in brightness, and an irrelevant indication caused by the influence of a special image processing, and these irrelevant indications need to be removed.

The feature value of defect on the film image is measured, and the result is compared with the irrelevant indication removal rule in the irrelevant indication database which has been collected in advance by the inspector, thereby eliminating the irrelevant indication.

By doing in this manner, according to this invention, all abnormalities are extracted for the enhancement of safety factor, whereas conventionally a defect is determined based on the threshold of brightness or density, and in addition to the brightness and density, the defect feature values including the shape and the distribution of brightness and density of defect and its periphery are introduced for screening along with the database of a skilled inspector so as to enhance the accuracy of discrimination.

In parallel to the emphasizing and extraction of a volumetric defect image of type 1, the emphasizing and extraction of a defect image which is elongated in the lateral direction along the planar welding line, such as a lack of fusion of type 2, are conducted. First, the emphasizing process for the brightness change in the direction of welding line is carried out as shown by the process 10 in Fig. 1. Because of a weak contrast of the image on the film as compared with a blow hole or the like of the type-1 defect, the use of the same method as for type 1 is inconvenient in that emphasizing is not possible due to the overwhelming brightness distribution of the background.

On this account, for a defect image of type 2, its nature of elongated shape in parallel to the welding line is used to implement a filtering process which emphasizes the brightness conversion along the welding line.

As shown in Fig. 5a, a rectangular window 22 is formed for a pixel 21 in attention at the center, the mean value of brightness in the window 22 is evaluated, and the brightness of the pixel 21 in attention is replaced with the mean value thereby to improve the contrast of defect image which is elongated in the lateral direction.
Next, as shown in Fig. 5b, a weighting factor -1 is multiplied to pixels that are distant by id pixels above and below the pixel 21 in attention and a weighting factor of 2 is multiplied to the central section, and these terms are totaled. By conducting a quadratic differential computation process for the total value as the value of the pixel in attention, the brightness component of the residual portion is removed, and the defect image which is elongated in the lateral direction is emphasized.

For this differential image, emphasizing modification of the pixel value is conducted in the same manner as for a defect of type 1. First, the emphasizing modification for the image at the end of the residual portion is carried out as shown by the process 12 in Fig. 1.

The process 12 implements the modification based on the logarithmic conversion so that the standard deviation $\sigma$ of the residual end section (low brightness portion is equal to the standard deviation $\sigma'$ of the welding center section (high brightness portion).

However, implementing such a conversion, in which the variance becomes equal through the emphasizing modification of the image at the residual end section, results in the emergence of a trend of a weakened image at the central section. For example, in the case of a lack of fusion, the contrast is relatively strong along the center line of the welding line in the region of a high brightness portion for which the statistic value is to be evaluated, or the image appears to have a large area. Accordingly, the standard deviation $\sigma'$ of a high brightness portion becomes extremely greater than $\sigma$ of a low brightness portion, and as a result of the process 12, the sensitivity of the high brightness portion is overwhelmed by that of the low brightness portion, resulting in the failure of emphasis for the defect image in the high brightness portion.

In this case, an image which has not been rendered the modification based on the logarithmic conversion of pixel value is used for an emphasized image at the welding center section in the process 13 of Fig. 1.

For the two emphasized images, which have been rendered the emphasizing modification in the residual end section and welding center section, the binary conversion of candidate defect image, shaping and irrelevant indication removal processes shown by the process 14 in Fig. 1 are carried out concurrently in the same manner as for the candidate defect image of type 1 described previously. By merging as a logical sum the binary images as results of extraction for these defect images of type 2, the extraction result 15 for the candidate defect image of type 2 is obtained.

Finally, merging and selection processes for the candidate defect images of type 1 and type 2 are implemented as shown by the process 16.

In the merging selection process for the candidate defect images of type 1 and type 2, the process of candidate defect image of the case where the extraction regions do not overlap is to retain all extracted regions of defect images of type 1 and to retain defect images of type 2 with the extraction region having a vertical to horizontal ratio of three or more or a length to width ratio in the inertial main axis direction of region of three or more, and to remove the remainder.

The process for a candidate defect image of the case where the extraction regions overlap is the selection based on the vertical to horizontal ratio of the extraction region, the selection based on the area, or the selection based on the distribution of brightness in the extraction region of the original image.

The foregoing irrelevant indication discrimination is summarized as listed in the following Table 1.

A candidate defect image before the application of the irrelevant indication removal rule shown in Table 1 to the result of extraction of a defect image which has been rendered the emphasized extraction process is shown in Fig. 6, and a candidate defect image after the application of the rule is shown in Fig. 7.

Images which undergo the image processing are not only images formed on the radiographic film, but images which are introduced directly through the image intensifier can also be applicable, as mentioned previously.

According to the first embodiment of this invention, for the radiographic test using the X rays or the like for such a weld defect as a blow hole and lack of fusion emerging in the welded portion or the like of a pipe or the like of a power plant facility, it is possible to extract a defective portion automatically and measure the shape and size of the defect automatically thereby to speed up the inspection and enhance the stability of the judgement result. In addition, the result of extraction is consistent with the result of the inspector. Setting of the threshold value of extraction is easy, and over sensitivity detection of defect images caused by the irrelevant indication removal process can be prevented.

Through the assumption of the distribution of pixel values of modified, emphasized images to be the normal distribution, the level of a candidate defect image including a defect image in the image can be defined in terms of the deviation value, whereby setting of the threshold value at the extraction of defect image is made easy.

Moreover, by measuring the feature value of defect related to the density and shape of an extracted candidate defect image, and by setting in advance the range of feature value of defect image which can be judged to be irrelevant indication by a skilled inspector so that irrelevant indication images are removed thoroughly by comparison, whereby over sensitive detection of defect images can be prevented and the efficiency of inspection can be enhanced.

By conducting the image emphasizing process for a volumetric defect image of type 1 and the image emphasizing process for a planar defect images of type 2 for the same image, it is possible to eliminate the failure of emphasis of defect images.

Moreover, an emphasized image converted into binary through the calculation of statistic value of pixel values of modified, emphasized image and subtraction of the threshold value multiplied by a certain parameter of the standard deviation from the mean value so that part of the candidate defect image can be extracted is conceivable to have a virtual normal distribution, and therefore the above-mentioned value of multiple of the standard deviation can be set easily by adjustment in the manner of probability.

Claims

1. Method for automatically extracting a weld defect image based on a radiographic transmission test in which data of an image taken by the radiographic transmission test is input into a computer and as preprocessing of said image data, noises are removed from said image data, an object area is sampled from said image data and a welding line portion (2) in the object area is extracted (4), wherein

- to obtain an image of a defect of type 1 being a volumetric defect, an emphasizing process based on the quadratic curve approximation of the brightness distribution is conducted (5, 7) in order to obtain an intermediary defect image, the original image is subtracted from the intermediary defect image, an emphasizing modification of the resulting differential image (6, 8) is performed and an automatic extraction of a candidate defect image and a removal of an irrelevant indication image are conducted (9, 11), and

- to obtain an image of a defect of type 2 being a defect elongated in a lateral direction along a planar welding line an emphasizing process based on a filtering process emphasizing the brightness conversion along the welding line is conducted (10), an emphasizing modification of the resulting image is performed (12, 13) and an automatic extraction of a candidate defect image and removal of an irrelevant indication image are conducted (14, 15);

7
EP 0 437 280 B1

- the defects of type 1 and type 2 are obtained in parallel, and
- the candidate images of defects of type 1 and type 2 are merged (16).

2. Method according to claim 1, wherein a quadratic curve approximation process in the direction of the welding line is conducted concurrently to the modification of a pixel value following the differential process in the direction normal to the welding line of the defect image of type 1, and the modification of the pixel value of the differential image is conducted after the differential process.

3. Method according to claim 1, wherein the emphasizing modification for a welding line central image and a residual end image is carried out concurrently following the emphasizing process of the brightness variation in the direction normal to the welding line of the defect image of type 2.

4. Method according to claim 1, wherein said irrelevant indication image is removed based on the comparison of measured data of the feature value of defect with a database which is based on the experience of an inspector.

5. Method according to claim 1, wherein said automatic extraction is carried out through a statistic process and binary conversion process for the brightness distribution.

6. Apparatus for automatically extracting a weld defect image based on a radiographic transmission test, comprising means for inputting data of an image taken by the radiographic transmission test into a computer and means for preprocessing said image data, which remove noises from said image data, sample an object area from said image data and extract a welding line portion (2) in the object area, wherein
- means are provided for obtaining an image of a defect of type 1 being a volumetric defect, which conduct an emphasizing process based on the quadratic curve approximation of the brightness distribution (5, 7) in order to obtain an intermediary defect image, subtract the original image from the intermediary defect image, perform an emphasizing modification of the resulting differential image (6, 8) and conduct an automatic extraction of a candidate defect image and a removal of an irrelevant indication image (9, 11),
- means are provided for obtaining an image of a defect of type 2 being a defect elongated in a lateral direction along a planar welding line, which conduct an emphasizing process based on a filtering process emphasizing the brightness conversion along the welding line (10), perform an emphasizing modification of the resulting image (12, 13) and conduct an automatic extraction of a candidate defect image and a removal of an irrelevant indication image (14, 15); and
- the means for obtaining the defect of type 1 and the means for obtaining the defect of type 2 operate in parallel and
- means are provided for merging the candidate images of defects of type 1 and type 2.

Patentansprüche

1. Verfahren zur automatischen Extraktion eines Bildes eines Schweißfehlers auf der Grundlage einer radiographischen Transmissionsprüfung, bei dem
   durch die radiographische Transmissionsprüfung erhaltene Daten eines Bildes in einen Computer eingegeben werden und als Vorerarbeitung der Bilddaten ein Rauschen aus den Bilddaten entfernt wird, ein Objektbereich aus den Bilddaten abgetastet wird und ein Schweißlinienabschnitt (2) in dem Objektbereich extrahiert wird (4), wobei
   - zum Erhalt eines Bildes eines Fehlers des Typs 1, der ein volumetrischer Fehler ist, ein Hervorhebungsprozeß auf der Grundlage der Quadratkurvenannahme der Helligkeitsverteilung ausgeführt wird (5, 7), um ein Zwischenbild des Fehlers zu erhalten, das Originalbild von dem Zwischenbild des Fehlers subtrahiert wird, eine Hervorhebungsmodifikation des sich ergebenden Differenzbilds (6, 8) ausgeführt wird und eine automatische Extraktion eines Bildes eines möglichen Fehlers und eine Entfernung eines Bildes irrelevanter Angaben erfolgen, und
   - zum Erhalt eines Bildes eines Fehlers des Typs 2, der in einer seitlichen Richtung entlang einer ebenen
Schweißlinie verlängerter Fehler ist, ein Hervorhebungsprozeß auf der Grundlage eines die Helligkeitsumwandlung entlang der Schweißlinie hervorhebenden Filterprozesses ausgeführt wird (10), eine Hervorhebungsmodifikation des sich ergebenden Bilds ausgeführt wird (12, 13) und eine automatische Extraktion eines Bilds eines möglichen Fehlers und eine Entfernung eines Bilds irrelevanter Angaben erfolgen (14, 15);

- die Fehler des Typs 1 und des Typs 2 parallel erhalten werden, und
- die Bilder möglicher Fehler des Typs 1 und des Typs 2 zusammengefügt werden (16).

4. Verfahren nach Anspruch 1, bei dem das Bild irrelevanter Angaben auf der Grundlage des Vergleichs der gemessenen Daten des Merkmalswerts des Fehlers mit einer Datenbank entfernt wird, die auf den Erfahrungen eines Inspektors basiert.

5. Verfahren nach Anspruch 1, bei dem eine automatische Extraktion über einen statistischen Prozeß und einen binären Umwandlungsprozeß für die Helligkeitsverteilung erfolgt.

6. Vorrichtung zur automatischen Extraktion eines Bildes eines Schweißfehlers auf der Grundlage einer radiographischen Transmissionsprüfung mit einer Einrichtung zur Eingabe von Daten eines durch die radiographische Transmissionsprüfung erhaltenen Bilds in einen Computer und einer Einrichtung zur Vorverarbeitung der Bilddaten, die ein Rauschen aus den Bilddaten entfernt, einen Objektbereich aus den Bilddaten abtastet und einen Schweißlinienabschnitt (2) in dem Objektbereich extrahiert, wobei

- eine Einrichtung zum Erhalten eines Bildes eines Fehlers eines Typs 1, der ein volumetrischer Fehler ist, vorgesehen ist, die einen Hervorhebungsprozeß auf der Grundlage der Quadratkurvenannäherung der Helligkeitsverteilung ausführt (5, 6), um ein Zwischenbild des Fehlers zu erhalten, das Originalbild von dem Zwischenbild des Fehlers subtrahiert, und eine Hervorhebungsmodifikation des sich ergebenden Differenzbilds (6, 8) sowie eine automatische Extraktion eines möglichen Fehlerbilds und eine Entfernung eines Bilds irrelevanter Angaben (9, 11) ausführt,

- eine Einrichtung zum Erhalten eines Bildes eines Fehlers eines Typs 2, der ein in einer seitlichen Richtung entlang einer ebenen Schweißlinie verlängerter Fehler ist, vorgesehen ist, die einen Hervorhebungsprozeß auf der Grundlage eines Filterprozesses ausführt, der die Helligkeitsumwandlung entlang der Schweißlinie hervorhebt (10), eine Hervorhebungsmodifikation des resultierenden Bilds (12, 13) sowie eine automatische Extraktion eines möglichen Fehlerbilds und eine Entfernung eines Bilds irrelevanter Angaben (14, 15) ausführt; und

- die Einrichtung zum Erhalten des Fehlers des Typs 1 und die Einrichtung zum Erhalten des Fehlers des Typs 2 parallel betrieben werden und

- eine Einrichtung zum Vereinigen der Bilder von möglichen Fehlern des Typs 1 und des Typs 2 vorgesehen ist.

Revendications

1. Procéédé pour extraire automatiquement une image de défaut de soudure basée sur un test de transmission radiographique dans lequel
des données d'une image obtenues par le test de transmission radiographique sont entrées dans un ordinateur et, lors d'un prétreatment desdites données d'image, des bruits sont supprimés desdites données d'image,
une zone d'objet est échantillonnée à partir desdites données d'image et une partie (2) de ligne de soudure située dans la zone d'objet est extrait (4), dans lequel

- pour obtenir une image d'un défaut du type 1 qui est un défaut volumétrique, un traitement d'accentuation basé sur l'approximation de la courbe quadratique de la répartition de brillance est effectué (5, 7), afin d'obtenir une image de défaut intermédiaire, l'image d'origine est soustraite de l'image de défaut intermédiaire, une modification de l'accentuation de l'image différentielle. Le résultat est réalisé et une extraction automatique d'une image de défaut candidate et une suppression d'une image d'indication non-pertinente sont effectuées (9, 11), et

- pour obtenir une image d'un défaut du type 2 qui est un défaut allongé dans une direction latérale le long d'une ligne de soudure plane, un traitement d'accentuation, basé sur un procédé de filtrage accentuant la conversion de brillance le long de la ligne de soudure, est effectué (10), une modification d'accentuation de l'image résultante est effectuée (12, 13) et une extraction automatique d'une image de défaut candidate et une suppression d'une image d'indication non-pertinente sont effectuées (14, 15),

- les défauts du type 1 et du type 2 sont obtenus en parallèle, et

- les images candidates de défauts du type 1 et du type 2 sont fusionnées (16).

2. Procédé selon la revendication 1, dans lequel un processus d'approximation de courbe quadratique dans la direction de la ligne de soudure est mené conjointement à la modification d'une valeur de pixel après le traitement différentiel dans la direction perpendiculaire à la ligne de soudure de l'image de défaut du type 1, et la modification de la valeur de pixel de l'image différentielle est effectuée après le traitement différentiel.

3. Procédé selon la revendication 1, dans lequel les modifications d'accentuation d'une image centrale de ligne de soudure et d'image d'extrémité résiduelle sont effectuées conjointement après le traitement d'accentuation de la variation de brillance dans la direction perpendiculaire à la ligne de soudure de l'image de défaut du type 2.

4. Procédé selon la revendication 1, dans lequel ladite image d'indication non-pertinente est supprimée sur la base de la comparaison des données mesurées de la valeur caractéristique d'un défaut avec une base de données qui est basée sur l'expérience d'une personne chargée d'inspecter.

5. Procédé selon la revendication 1, dans lequel ladite extraction automatique est effectuée par l'intermédiaire d'un traitement statistique et d'un traitement de conversion binaire de la répartition de brillance.

6. Dispositif pour extraire automatiquement une image de défaut de soudure sur la base d'un test de transmission radiographique, comportant des moyens pour entrer dans un ordinateur des données d'une image obtenues par le test de transmission radiographique et des moyens pour traiter lesdites données d'image, qui suppriment des bruits desdites données d'image, échantillonnent une zone d'objet à partir desdites données d'image et extraient une partie (2) de ligne de soudure située dans la zone d'objet, dans lequel

- des moyens sont prévus pour obtenir une image d'un défaut du type 1 qui est un défaut volumétrique, qui réalisent un traitement d'accentuation basé sur l'approximation de la courbe quadratique de la répartition de brillance (5, 7), afin d'obtenir une image de défaut intermédiaire, soustraient l'image d'origine de l'image de défaut intermédiaire, réalisent une modification d'accentuation de l'image différentielle résultante (6, 8) et réalisent une extraction automatique d'une image de défaut candidate et une suppression d'une image d'indication non-pertinente (9, 11),

- des moyens sont prévus pour obtenir une image d'un défaut du type 2 qui est un défaut allongé dans une direction latérale le long d'une ligne de soudure plane, qui réalisent un traitement d'accentuation basé sur un procédé de filtrage accentuant la conversion de brillance le long de la ligne de soudure (10), réalisent une modification d'accentuation de l'image résultante (12, 13) et effectuent une extraction automatique d'une image de défaut candidate et une suppression d'une image d'indication non-pertinente (14, 15), et

- les moyens pour obtenir le défaut du type 1 et les moyens pour obtenir le défaut du type 2 agissent en parallèle, et

- des moyens sont prévus pour fusionner les images candidates de défaut du type 1 et du type 2.
