Method and apparatus for gaging bodies such as threaded fasteners and blanks.

Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).
Description

This invention is directed to a method and apparatus for gaging bodies and is particularly concerned with an improved method and apparatus for gaging threaded fasteners and/or fastener blanks.

Such gaging is preferably carried out in order to determine deviations of the dimensions of such fasteners and/or blanks from the specified or desired dimensions, which data may be utilized for statistical in-process control, for lot control and the like. While the method and apparatus of the invention may be utilized with both round body or poly-arcuate or lobular bodied fasteners and their blanks, as well as other similar bodies such as round or poly-arcuate pins, shafts, shanks or the like, the ensuing discussion will be directed primarily to the gaging of poly-arcuate or lobular fasteners. The use of the term "fastener" herein should be understood as including both a fastener blank and a threaded fastener manufactured from such a blank.

The gaging of lobular fasteners has traditionally been a somewhat complicated task, because the degree of lobulation of out-of-roundness is just as important as the basic thread dimensions in the formation of these fasteners. The degree of lobulation, or out of round, is usually defined as half the diametral difference between the inscribed and circumscribed circles of a cross-section arcuate form of the fastener. Such lobular fasteners are used extensively both as thread-forming screws and for self-locking, or sealing purposes in pre-tapped holes. In either of these general applications control of the degree of lobulation is important in assuring proper performance of the product. For example, this degree of lobulation (commonly designated K) must exceed a certain minimum for thread-forming with a reasonable driving effort or for entry into a preformed thread and adequate sealing or self-locking with acceptable driving effort. On the other hand, if this K or degree of lobulation exceeds a certain maximum amount, the tensile load-carrying ability of the joint in the work may be seriously compromised, due to reduced surface thread contact area of the threads.

In the past, conventional screw threads have often been measured by threading each fastener to be tested into each of a pair of so-called ring or functional gages, which have internal threads corresponding with maximum and minimum allowable external thread dimensions of the fastener. An acceptable product was considered to be one which could be threaded into the maximum gage but not into the minimum gage. However, it should be recognized that non-entry into the minimum gage could be the result of only a single over-size thread element or portion, and would not imply any control whatever on the individual minimum thread dimensions of the fastener. In recent years this condition has been alleviated somewhat through the use of pitch diameter micrometers, individual element indicator gages and other techniques.

Past methods of gaging the cross-sectional dimensions of lobular thread-forming and self-locking screws used hand micrometers. In a first measurement, a multi-anvil type micrometer was used, in which the fastener was rotated to obtain the maximum reading; that is, the diameter of the circumscribing circuit "C". In a second operation, a more or less conventional micrometer was used to obtain the "D" dimension, which is a cross-section from a high point of one lobe to a low point opposite. It was not the practice, however, to calculate the difference between these two micrometer readings; i.e., the K, or out of round dimension. That is, the dimensions C and D of the fastener alone, even if themselves within acceptable limits, do not guarantee an acceptable K or out of round dimension. Moreover, the two-step inspection process utilizing two micrometers is quite cumbersome to perform, is time-consuming, requiring individual handling and inspection of each part to be inspected and gaged in this method, and also effectively doubles the potential for measurement error.

US Patent No. 3879854 discloses a method of and apparatus for gaging external screw threads in which gaging means includes a plurality of elements which engage a peripheral surface of the thread under test, one of the gaging elements being radially movable relative to the thread under test and cooperating with lever means which translates movement of the gaging element into a reading on an indicator.

It is a general object of the invention to provide a novel and improved method and apparatus for gaging the degree of lobulation of threaded fasteners and or fastener blanks, and in particular, such a method and apparatus which can readily determine the K dimension of a lobular fastener.

According to one aspect of the present invention, a method for gaging the degree of lobulation of a body comprising one of a threaded fastener and a blank for a threaded fastener comprises providing gage means comprising a plurality of support elements in a spaced circumferential array about a central axis for supporting and engaging a peripheral surface of the body at spaced intervals thereabout; at least one but not all of said support elements being movable with said peripheral surface of said body during rotation of said body; rotating said body; the method being characterised by recording information corresponding to said movement of said at least one of said support elements during said rotating of said body to form recorded data; and calculating from said recorded data the diameter of a circle circumscribing said body and the diameter of a circle inscribing said body and one-half of the difference therebetween; said one-half of said difference being defined as the degree of lobulation of said body.
According to another aspect of the present invention, apparatus for measuring the degree of lobulation of a body comprising one of a threaded fastener and a blank for a threaded fastener, comprises gage means comprising at least three support elements in a spaced circumferential array about a central axis and located substantially symmetrically for surrounding engagement and supporting said body while permitting rotation thereof; at least one but not all of said support elements being movable relative to said central axis so as to contact and follow said peripheral surface of said body as said body is rotated; and is characterised by recording means responsive to the movement of said at least one of said support elements during rotation of said body for recording information corresponding to said movement to form recorded data; and by data processing means for developing information including the degree of lobulation of the body from said recorded data; wherein said data processing means includes means for calculating the diameters of a circumscribing circle and an inscribing circle of said body and one-half of the difference between said diameters, said one-half of said difference between said diameters being defined as the degree of lobulation of said body.

The features of the present invention which are believed to be novel are set forth with particularity in the appended claims. The organization and manner of the operation of the invention, together with further objects and advantages thereof may best be understood by reference to the following description, taken in connection with the accompanying drawing in which like reference numerals identify like elements, and in which:

Fig. 1 is a view of an apparatus in accordance with the invention, suitable for carrying out the method of the invention.

Fig. 2 is a diagrammatic cross-sectional view of a trilobular body indicating various dimensions and dimensional relationships thereof.

Fig. 3 is an enlarged, partial cross-sectional view of a roller-type gage instrument of the apparatus of Fig. 1, taken on the line 3-3 of Fig. 1;

Fig. 4 is an enlarged, partial cross-sectional view of a second roller-type gage instrument forming a part of the apparatus of Fig. 1, taken on the line 4-4 of Fig. 1;

Figs. 5 and 6 are enlarged partial views, partially in cross-section of the respective roller gage apparatuses of Fig. 1;

Fig. 7 is an enlarged, partial cross-sectional view through a grooved roller apparatus of a form for engagement with a threaded fastener having a conventional thread form;

Fig. 8 is a cross-section similar to Fig. 7 showing a modified form of grooved roller formed for engagement with a threaded fastener having a modified thread form;

Fig. 9 is a cross-sectional view similar to Figs. 7 and 8 but showing engagement of a threaded fastener by the smooth-faced roller of Fig. 4; and Figs. 10 and 11 illustrate engagement of a trilobular fastener with an alternate form of gaging instrument illustrated in Fig. 1.

Referring now to the drawings and initially to Fig. 1, there is shown an apparatus in accordance with the invention which is also suitable for carrying out the method of the invention. The apparatus includes at least one gage apparatus or gage means such as a roller-type gage 20, which will be more fully described hereinbelow. In the illustrated embodiment, a second similar roller-type gage 22, also to be more fully discussed hereinbelow is also provided. Alternatively, a gage of the type indicated by reference numeral 24 in Fig. 1 might be utilized, although roller-type gages such as gages 20 and 22 are preferred. The alternate type gage 24 is of the type referred to as a V-anvil micrometer.

The method of the invention gages the out of round or so-called K dimension of a fastener which may be a threaded fastener or an unthreaded fastener blank, as the term "fastener" is to be understood, when used hereinafter. The fastener may be polycrystalline or lobar in shape, or round. In the former case, the K dimension may also be referred to as the degree of lobulation. However, the ensuing description is facilitated by reference particularly to a trilobular body 30, which may be a fastener blank or a trilobular threaded fastener. A trilobular body 30 is indicated generally in Fig. 2. An unthreaded trilobular blank, which is designated by reference numeral 30a is shown in Figs. 1 and 6, while a completed threaded trilobular fastener designated by reference numeral 30b is shown in Figs. 1 and 5. The fastener 30b may also be provided with a tapered or conical lead-in surface or tip 35, such as in a thread-forming type of fastener.

The trilobular body 30 in the example shown in the drawings, is placed in surface-to-surface contact with one or both of the gages 20 and 22 shown in Fig. 1 for measuring the dimensions C, E which correspond respectively to diameters of circumscribing and inscribing circles 32, 34 of the trilobular body 30. The orientation of a body 30 (which may be blank 30a or threaded fastener 30b) with respect to the gage 20 is indicated in cross-section and somewhat diagrammatically in Fig. 3. In similar fashion, the engagement of a threaded fastener 30b with the gage 22 is shown in somewhat diagrammatic cross-sectional form in Fig. 4. A somewhat enlarged view of the gages 20 and 22 as illustrated in Fig. 1 are found in Fig. 5 (gage 22) and in Fig. 6 (gage 20). Typical gaging of the circumscribing and inscribing circles for a trilobular body 30 generally with the anvilt-type micrometer 24 are shown in Figs. 10 and 11, respectively. The ensuing discussion will refer, in additional detail to the gages
as illustrated in these respective figures of drawing and to the gaging method of the invention for gaging both threaded and unthreaded fasteners, both of poly-arcuate and round form, as well as similar bodies, to determine out-of-roundness thereof.

Referring to Fig. 1, the apparatus and method of the invention proceed by recording data corresponding to the measurements made by the respective gauges and ascertaining a predetermined relationship between the inscribed circle and circumscribed circle from this recorded data. The means for recording and processing the data is indicated at Fig. 1 as a data-processing unit 26. An additional CRT type display 28 may also be coupled with the data-processing unit 26 to display data associated with these measurements. We have selected as a data-processing unit 26 a DATABank Plus System from Brown & Sharpe, Inc., North Kingstown, R.I. We have modified the DataBank Plus software, as indicated in the microfiche appendix. Any CRT display may be used, we have selected a Wyse monitor.

Referring now to Fig. 2, we have discovered that useful statistical data for manufacturing control and batch processing can be obtained by determining the difference between the respective pitch cylinder diameters corresponding to the respective inscribed or inscribing circle 34 (E) and circumscribed or circumscribing circle 32 (C) of a poly-arcuate or lobular body. One-half of this difference constitutes the K or out of round dimension of the body. In this regard it will be seen that a trilobular body has been illustrated in diametral cross-section in Fig. 2. This trilobular body 30 has a geometry as is generally described in U.S. patent to Phipard, No. 3,195,156, for example. That is, the trilobular cross-sectional shape will be seen to have three lobes 40, 42, 44 that are separated by arcuate sides 50, 52, 54 such that the lobes generally define an arcuate equilateral triangle. The circumscribing circle 32 or diameter C will be seen to form tangents to the three lobes, while the inscribing circle 34 or diameter E forms a tangent to the arcuate sides.

As mentioned hereinabove, we have found that one-half of the difference between these diametral dimensions, sometimes designated as the K dimension, out of round, or degree of lobulation of the lobular shape, is a significant measurement in determining product geometry acceptability.

Briefly, when using the anvil-type micrometer 24, and referring to Figs. 10 and 11, the circumscribing circle is measured as shown in Fig. 10 by placing the lobes 40, 42 and 44 of the body 30 in contact with the respective three relevant surfaces of the micrometer. It will be seen in this regard that the micrometer has a generally V-shaped anvil portion 46 and a selective ly advanceable and retractable, preferably flat-ended cylindrical spindle member 48. Similarly, as seen in Fig. 11, the inscribing circle diameter is obtained by placing the arcuate sides 50, 52 and 54 in surface-to-surface contact with the respective flat internal surfaces of the V-shaped anvil 46 and the spindle 48.

While the method and apparatus have been described thus far with reference to a trilobular body 30, it should be recognized that the apparatus and method herein described is also applicable to measuring unacceptable ovality of out-of-roundness of round-bodied fasteners whether threaded or unthreaded blanks, as well. Often this condition goes undetected using presently available gaging systems.

Referring now in more detail to Figs. 3-9, the method and apparatus for obtaining these measurements with the roller-type gauges 20, 22 is illustrated. Initially, it will be seen that each of the roller-type gauges 20, 22 includes a plurality of rollers in a spaced circumferential array about a central axis. While any suitable commercially available gage components may be utilized, we have selected an Electronic Dial Indicator from Brown & Sharpe, Inc., North Kingstown, R.I., and a roller gage from Johnson Gage, Bloomfield, Conn. Alteration of the number and positioning of rollers, as may be required for polygonal or poly-arcuate shapes other than trilobular, is within the scope of the invention. In the illustrated embodiment, preferably three such rollers 60, 62, 64 and 70, 72, 74 are arrayed at 120° intervals about central axes 65, 75. It will be seen that, when a body 30, (be it threaded fastener 30a or blank 30b) is inserted into each gage, its axis is also coincident with the central gage axis 65, 75.

The rollers 60, 62 and 64 of gage 20 are arranged with smooth surfaces for contacting an outer surface of the body to be measured, which body may be an unthreaded member such as blank 30a or a threaded fastener such as fastener 30b, as well as being either lobular or round in form. These rollers can measure both the circumscribed circle 32 and the inscribed circle 34 of an outer surface of the body as the body to be measured is rotated therewithin. In the case of a threaded fastener such as fastener 30b, these measurements will yield a measure of the K, or out of round dimension of the outer diameter or thread crest diameters of the fastener.

In the case of a threaded fastener such as fastener 30b, an additional gage such as gage 22, which employs grooved rollers 70, 72 and 74, arranged for measuring the C and E dimensions corresponding to the circumscribing and inscribing circles 32, 34 at the pitch line or pitch diameter of the thread. This measurement by the use of grooved rollers is illustrated further in Figs. 7 and 8. The measurement of the crest or outer diameter of the threads by rollers of the gage 20 is illustrated with respect to roller 62, for example, in Fig. 9. Accordingly, for a threaded fastener two separate out of round or K dimensions will be determined, one for the outer diameter of the thread and one for the pitch line diameter of the thread.

Accordingly, the rollers 60, 62 and 64 are gener-
ally right cylindrical members having smooth continuous surfaces. However, the rollers 70, 72 and 74 are circumferentially grooved. These grooves, indicated by reference numeral 80 in Fig. 7, and an alternative groove form indicated by reference numeral 80a in Fig. 8 are shaped to make contact with the threads of a thread fastener in such a way as to effect the measurement of the C and E dimensions at the pitch line or pitch diameter of the fastener. Moreover, the respective grooves 80 and 80a are further shaped in complementary form to the pitch or shapes of the threads which they are intended to measure at the pitch line. For example, the grooves 80 of Fig. 6 are generally tapered in a complementary fashion for entering the threads of the fastener 30b shown therein.

On the other hand, exemplary fastener 130b of Fig. 8 has a somewhat different thread pitch profile and hence the grooves 80a are somewhat more rectangularly shaped at their inner aspects and convergent at their outer aspects to accommodate this thread-form of fastener 130b. The thread form of fastener 130b is generally that described in U.S. patent 4,820,098 to Taubert et al, wherein the flank angle of the thread is on the order of 60° and the flank angle of the thread crests extending beyond the nominal diameter of the screw is on the order of 30°. Accordingly, the form of the grooves 80a is varied somewhat to accommodate this sort of thread form. The form of the grooves 80, 80a may be further varied as appropriate for any desired thread form angle design without departing from the invention. That is, the grooved rollers 70, 72, 74 are shaped to contact the fastener in such a way as to measure the C and E dimensions at the pitch line. The actual form of the grooves may be said to be complementary with the thread pitch angle or thread form of the fastener to be so measured.

In accordance with the method and apparatus of the invention, suitable direct indicators or indicator means 90, 92 and 94 may also be provided on the respective gages 20, 22 and 24 for a direct read-out of the respective fastener dimensions as they are gagged.

The method and apparatus of the invention also contemplate measuring the shape or envelope of a tapered, lead in or thread-forming portion 35 (see Fig 5) of a thread forming type of fastener. This is preferably accomplished using the roller-type gages 20, 22 as best viewed in Figs. 4 and 5. In accordance with the method of the invention, the lead-in portion of the fastener is rotated several full 360° turns within the rollers, thus axially advancing the same somewhat relative to the rollers. The data developed in response to this rotation and advancement can be further utilized by the data-processing means 26 to develop data representative of the shape or envelope of the lead-in portion of such a fastener. In the gaging of the "full threads" of the body away from the lead-in portion of the fasteners, the method of the invention contemplates rotating the fastener 30 substantially 360° and obtaining statistical data therefrom for determining the "aggregate" out-of-round dimension of the fastener.

In the case of thread rolling or thread-forming screws, it is estimated that as much as 95% or more of the work or effort in forming internal threads is performed by the lead threads. The lead threads may be considered to be enveloped or circumscribed within a lobular, frustoconical shape with lobes corresponding in number with those of the body threads. The angle of this cone and number of lead threads is governed by the individual product specifications from one fastener to another. However, it will be appreciated that the C and E dimensions will therefore vary from thread to thread, along this tapered lead-in portion. The driving effort in the installation of such a thread-rolling or thread-forming screw is generally indicated by the applied torque measured over the degrees of rotation (expressed in radians) of the screw. As the screw is driven, the rotation is accompanied by a progressive radial outward movement of the lead threads with increasing torque in forming complementary internal mating threads in the workpiece or nut. Consequently, the method and apparatus of the invention may also be used in evaluating the relationship of the K or out-of-round dimension to the rotation of the lead threads of such a thread-forming fastener, to assure the same are formed in such a manner as to obtain the desired driving effort and thread forming action.

Using the method and apparatus of the invention, the depth of the grooves 80 would be dictated by product specifications, as mentioned above. However, this could be varied up to .325 P (pitch). As the point threads are captured within the grooved rolls and the screw is rotated, the gage readings will follow the generally undulating pattern of the lobular form with the measured values increasing along a slope generally the same as the slope of the point angle of the lead threads until the body threads of a uniform or constant width or diameter are reached. Accordingly, a measure is obtained of radial penetration of the threads against rotation of the fastener and the gradual formation of complementary internal or mating threads in a workpiece. This path of radial penetration versus rotation can be plotted or recorded in appropriate fashion by the data-processing means 26 and for display upon the display means 28. The taper of the lead-in portion may also be measured against a desired specification for the product by use of the method and apparatus of the invention.

We prefer the use of the roller-type gages over the method using the so-called V-anvil gage as discussed above with reference to Figs. 10 and 11. In using the anvil gage, it is necessary to hold the body to be measured stationary during measurement, and it is necessary to properly and accurately position the body, as shown in Figs. 10 and 11, to obtain the prop-
er dimensional measurements. In practice, this may be done by rotating the body slightly and accepting or recording only the maximum and minimum relative readings as being representative of the respective circumscribed and inscribed circle diameters. It will be appreciated that with a full 360° rotation of the body as contemplated when using the roller type gages 20, 22, slight variations or irregularities of the fastener will also be measured and taken into account in arriving at an aggregate degree of lobulation or out-of-round or K reading, or data measurement.

The invention further contemplates developing statistical data from measurements taken on a plurality of bodies or fasteners, which data may be utilized in lot control or processing control applications. The method also contemplates determining from the recorded data points of maximum deviation on the inscribed circle and circumscribed circle diameters of each body or fastener as related to mean measured values thereof.

It will be further noted that the measurement of the out-of-round or K dimension accomplished by the apparatus and method of the invention also effectively results in a measurement of what is normally called the pitch diameter or effective diameter in the case of a threaded fastener.

A program listing of modifications to the above-identified Databank Plus software for operating the data processor in accordance with the invention has been submitted herewith as a microfiche appendix.

While particular embodiments of the invention have been shown and described in detail, it will be obvious to those skilled in the art that changes and modifications of the present invention, in its various aspects, may be made without departing from the invention in its broader aspects, some of which changes and modifications being matters of routine engineering or design, and others being apparent only after study. As such, the scope of the invention should not be limited by the particular embodiment and specific construction described herein but should be defined by the appended claims and equivalents thereof.

Claims

1. A method for gaging the degree of lobulation of a body (30) comprising one of a threaded fastener and a blank for a threaded fastener, said method comprising: providing gauge means (20, 22, 24) comprising a plurality of support elements (60, 62, 64; 70, 72, 74) in a spaced circumferential array about a central axis (65,75) for supporting and engaging a peripheral surface of the body at spaced intervals thereabout; at least one but not all of said support elements being movable with said peripheral surface of said body during rotation of said body; rotating said body; characterised by recording information corresponding to said movement of said at least one of said support elements during said rotating of said body to form recorded data; and calculating from said recorded data the diameter of a circle (32) circumscribing said body and the diameter of a circle (34) inscribing said body and one-half of the difference therebetween; said one-half of said difference being defined as the degree of lobulation of said body.

2. A method according to Claim 1, wherein said calculating comprises calculating the degree of lobulation for a plurality of bodies (30) and developing therefrom statistical in-process control data.

3. A method according to Claim 1 or Claim 2, wherein in the step of calculating further includes calculating mean values of the diameters of said inscribing (34) and circumscribing (32) circles and determining points of maximum deviation from said mean values.

4. Apparatus for measuring the degree of lobulation of a body (30) comprising one of a threaded fastener and a blank for a threaded fastener, said apparatus comprising: gage (20, 22) means comprising at least three support elements (60, 62, 64; 70, 72, 74) in a spaced circumferential array about a central axis (65,75) and located substantially symmetrically for surroundingly engaging and supporting said body (30) while permitting rotation thereof; at least one but not all of said support elements being movable relative to said central axis so as to contact and follow the peripheral surface of the body as the body is rotated; characterised by recording means (26) responsive to the movement of said at least one of said support elements during rotation of said body for recording information corresponding to said movement to form recorded data; and data processing means (26) for developing information including the degree of lobulation of the body from said recorded data; wherein said data processing means includes means for calculating the diameters of a circumscribing circle (32) and an inscribing circle (34) of the body (30) and one-half of the difference between said diameters, said one-half of the difference between the diameters being defined as the degree of lobulation of said body.

5. Apparatus according to Claim 4, wherein said support elements (60, 62, 64; 70, 72, 74) provide at least three support surfaces for supporting said peripheral surface of said body at intervals
spaced by substantially 120 degrees, at least one but not all of said support surfaces being movable to follow the peripheral surface of the body as the body is rotated.

6. Apparatus according to Claim 4 or Claim 5, wherein said support elements comprise three rollers (60, 62, 64; 70, 72, 74) and a shaft supporting each of said rollers for contacting and rotating with said body (30) during rotation thereof, at least one but not all of said shafts being movable relative to said central axis for permitting its associated roller to maintain contact with and follow the peripheral surface of said body during rotation thereof; said associated roller comprising said at least one of said support elements.

7. Apparatus according to Claim 6, wherein said rollers have smooth, right cylindrical surfaces for engaging said body.

8. Apparatus according to Claim 6, wherein each of said rollers (70, 72, 74) comprises a right cylindrical member having a plurality of spaced circumferential grooves (80) arranged for complementary engagement with a thread of a threaded fastener (30b) comprising said body to be gaged, for determining the degree of lobulation substantially at the pitch diameter of the threaded fastener.

Patentansprüche

1. Verfahren zum Messen des Maßes der Lobularität eines Körpers (30), der einen Gewindebefesti- ger oder einen Rohling für einen Gewindebefesti- ger aufweist, mit den Verfahrensschritten: Bereitstellen von Meß-Mittel (20, 22, 24) mit ei- ner Mehrzahl von Stütz-Elementen (60, 62, 64; 70, 72, 74) in einem beobachteten Umfangsfeld um eine zentrale Achse (65, 75) zum Stützen von und Eingreifen in eine(r) Umfangsfläche des Kör- pers an beobachteten Intervallen; wobei minde- stens eines, aber nicht alle der Stütz-Elemente mit der Umfangsfläche des Körpers während der Rotation des Körpers bewegbar sind; Rotieren des Körpers; gekennzeichnet durch die Aufnah- me von Information, die der Bewegung minde- stens eines der Stütz-Elemente während der Ro- tation des Körpers entspricht, um Aufnahmeda- ten bereitzustellen; und die Berechnung des Durchmessers eines den Körper umschreibenden Kreises (32) und des Durchmessers eines in dem Körper einbeschriebenen Kreises (34) sowie der Hälfte der Differenz zwischen ihnen aus den Aufnahmedaten; wobei die Hälfte der Differenz definiert ist als das Maß der Lobularität des Körpers.

2. Verfahren nach Anspruch 1, dadurch gekennzeichnet, daß die Berechnung ei- ne Berechnung des Maßes der Lobularität für ei- ne Mehrzahl von Körnern (30) sowie daraus die Ermittlung von statistischen Herstellungs- Steuerdaten einschließt.

3. Verfahren nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß die Berechnung weiterhin die Berechnung von Mittelwerten der Durchmesser der einbeschriebenen Kreise (34) und umschreibenden Kreise (32) sowie die Be- stimmung der Punkte der maximalen Abweichung von den Mittelwerten einschließt.

4. Vorrichtung zum Messen des Maßes der Lobularität eines Körpers (30), der einen Gewindebefesti- ger oder einen Rohling für einen Gewindebefesti- ger enthält, mit: Meßvorrichtungen (20, 22) mit mindestens drei Stütz-Elementen (60, 61, 64; 70, 72, 74), die in ei- nem Umfangsfeld um eine zentrale Achse (65, 75) beobachtet und im wesentlichen symme- trisch für einen umschließenden Eingriff und ein Abstützen des Körpers (30) angeordnet sind, während sie eine Rotation desselben erlauben; wobei mindestens eines aber nicht alle der Stütz-Elemente in Bezug auf die zentrale Achse dreh- bar ist, die Umfangsfläche des Körpers zu be- rühren und ihr zu folgen, wenn der Körper rotiert wird; gekennzeichnet durch Aufnahme-Mittel (26), die auf die Bewegung des mindestens einen der Stütz-Elemente während der Rotation des Körpers ansprechen zur Aufnahme von Informa- tionen, die der Bewegung entspricht, um Aufnah- medaten bereitzustellen; Datenverarbeitungs-Mittel (26) zum Herstellen von Informationen einschließlich des Maßes der Lobularität des Körpers aus den Aufnahmedaten; wobei die Datenverarbeitungs-Mittel Mittel zum Berechnen der Durchmesser eines umschreibenden Kreises (32) und eines einbeschriebenen Kreises (34) des Körpers (30) sowie der Hälfte der Differenz zwischen diesen Durchmessern enthalten, wobei die Hälfte der Differenz zwi- schen den Durchmessern als Maß der Lobularität des Körpers definiert ist.

5. Vorrichtung nach Anspruch 4, dadurch gekennzeichnet, daß die Stütz-Elemente (60, 62, 64; 70, 72, 74) mindestens drei Stützflächen zum Stützen der Umfangsfläche des Körpers an im wesentlichen um 120° ver- setzten Intervallen bereitzustellen, wobei minde- stens eine, aber nicht alle der Stützflächen be- weglich sind, um der Umfangsfläche des Körpers zu folgen, wenn der Körper rotiert wird.
6. Vorrichtung nach Anspruch 4 oder 5, dadurch gekennzeichnet, daß die Stütz- 
   Elemente drei Rollen (60, 62, 64; 70, 72, 74) und 
   jeweils eine die Rollen tragende Welle aufweisen 
   für eine Berührung und Rotation mit dem Körper 
   (30) während dessen Rotation, wobei minde-
   stens eine aber nicht alle der Wellen in Bezug auf 
   die zentrale Achse bewegbar sind, um die zuge- 
   hörige Rolle in Kontakt mit der Oberfläche des 
   Körpers während dessen Rotation zu halten und 
   ihr dabei zu folgen; wobei die zugehörige Rolle 
   mindestens eines der Stütz-Elemente aufweist.

7. Vorrichtung nach Anspruch 6, 
   dadurch gekennzeichnet, daß die Rollen für ei-
   nen Eingriff mit dem Körper glatte, gerade zylind-
   drische Oberflächen aufweisen.

8. Vorrichtung nach Anspruch 6, 
   dadurch gekennzeichnet, daß jede der Rollen 
   (70, 72, 74) ein gerades zylindrisches Element 
   aufweist, das eine Mehrzahl von beobstandeten 
   umfänglichen Nuten (80) aufweist, die für einen 
   komplementären Eingriff mit einem Gewinde ei-
   nes Gewindebefestigers (30 b) vorgesehen sind, 
   welcher den zu messenden Körper enthält, zum 
   Bestimmen des Maßes der Lobularität im we-
   sentlichen an dem Flankendurchmesser des Ge-
   windebefestigers.

Revidierung

1. Procédé de calibrage du degré de lobulation d’un 
   corps (30) comprenant un organe fileté de fixa-
   tion ou une ébauche d’organe filetée de fixation, 
   le procédé comprenant la disposition d’un dispo-
   sitif à calibre (20, 22, 24) ayant plusieurs élé-
   ments de support (60, 62, 64; 70, 72, 74) formant 
   un ensemble circonférentiel espacé autour d’un 
   axe central (65, 75) pour le support d’une surface 
   périphérique du corps et son contact à des inter-
   valles espacés autour de cette surface, l’un au 
   moins, mais non la totalité, des éléments de sup-
   port étant mobile avec la surface périphérique du 
   corps lors de la rotation du corps, et I’entraîne-
   ment en rotation du corps, caractérisé par l’erre-
   gistrement d’informations correspondant à ce dé-
  placement de l’un au moins des éléments de sup-
   port pendant l’entraînement en rotation du corps 
   pour la formation de données enregistrées, et le 
   calcul, à partir des données enregistrées, du dia-
   mètre d’un cercle (32) circonscrit au corps et du 
   diamètre d’un cercle (34) inscrit dans le corps, et 
   de la moitié de leur différence, cette moitié de la 
   différence étant définie comme étant le "degré de 
   lobulation" du corps.

2. Procédé selon la revendication 1, dans lequel le 
   calcul comprend le calcul du degré de lobulation 
   de plusieurs corps (30) et la détermination de 
   données statistiques de commande de traitée-
   ment à partir de ces résultats.

3. Procédé selon la revendication 1 ou 2, dans le-
   quel l’étape de calcul comporte en outre le calcul 
   des valeurs moyennes des diamètres des cercles 
   inscrit (34) et circonscrit (32), et la détermination 
   des points d’écart maximal par rapport aux va-
   leurs moyennes.

4. Appareil de mesure du degré de lobulation d’un 
   corps (30) sous forme d’un organe fileté de fixa-
   tion ou d’une ébauche d’un tel organe fileté, l’appa-
   reil comprenant un dispositif à calibre (20, 22) 
   qui comporte au moins trois éléments de support 
   (60, 62, 64; 70, 72, 74) ayant une disposition cir-
   conférentielle espacée autour d’un axe central 
   (65, 75) et placés de manière pratiquement symé-
   trique afin qu’ils supportent le corps (30) en l’en-
   tourant tout en permettant sa rotation, l’un au 
   moins des éléments de support, mais non la to-
   talité, étant mobile par rapport à l’axe central afin 
   qu’il soit au contact de la surface périphérique du 
   corps et la suivre lorsque le corps tourne, carac-
   térisé par un dispositif (26) d’enregistrement 
   commandé par le déplacement dudit élément au 
   moins de support pendant la rotation du corps 
   afin que les informations correspondant au dé-
   placement soient enregistrées et forment des 
   données enregistrées, et un dispositif (26) de 
   traitement de données destiné à créer des infor-
   mations comprenant le degré de lobulation du 
   corps à partir des données enregistrées, et le dis-
   positif de traitement de données comporte un 
   dispositif de calcul des diamètres d’un cercle cir-
   conscrit (32) et d’un cercle inscrit (34) du corps 
   (30) et de la moitié de leur différence, la moitié de 
   la différence entre les diamètres étant définie 
   comme étant le "degré de lobulation" du corps.

5. Appareil selon la revendication 4, dans lequel les 
   éléments de support (60, 62, 64; 70, 72, 74) for-
   ment au moins trois surfaces de support de la 
   surface périphérique du corps à des intervalles 
   espacés de 120° pratiquement, l’une au moins 
   des surfaces de support, mais pas la totalité, 
   étant mobile afin qu’elle suive la surface périphé-
   rique du corps lorsque celui-ci tourne.

6. Appareil selon la revendication 4 ou 5, dans le-
   quel les éléments de support comprennent trois 
   galets (60, 62, 64; 70, 72, 74) et un arbre suppor-
   tant chacun des galets afin que le galet soit au 
   contact du corps (30) et tourne avec lui pendant 
   sa rotation, l’un au moins des arbres, mais non la
totalité, étant mobile par rapport à l’axe central afin que le galet associé puisse rester au contact de la surface périphérique du corps et suivre cette surface pendant la rotation du corps, le galet associé formant l’élément de support au moins.

7. Appareil selon la revendication 6, dans lequel les galets ont des surfaces lisses sous forme de cylindres de section droite circulaire, destinées à être au contact du corps.

8. Appareil selon la revendication 6, dans lequel chacun des galets (70, 72, 74) est un organe en forme de cylindre de section droite circulaire ayant plusieurs gorges circonférentielles espacées (80) destinées à coopérer de manière complémentaire avec un filetage d’un corps fileté (30b) constituant le corps à calibrer, pour la détermination du degré de lobulation pratiquement au diamètre primitif de l'organe fileté de fixation.
