Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).
Description

This invention relates to a drill with replaceable cutting inserts for forming holes in metal workpieces and, more particularly, to a drill having cutting inserts which may be easily removed and replaced after the cutting edges become worn.

A drill with a pair of indexable cutting inserts is disclosed in United States Patent 3,963,365. In that drill, one insert is an outer insert which removes metal from the peripheral wall of the hole and inwardly toward the center of the hole in a cutting arc whose width is equal to one-half the radius of the hole. The other insert is an inner insert which removes metal from the center of the hole and outwardly toward the peripheral wall of the hole in a cutting arc of substantially equal width.

While drills of the type disclosed in the US Patent 3,963,365 have enjoyed significant commercial success, the axial feed rate of such a drill is relatively slow due to the fact that a full revolution of the drill is required to cut the full circumference of the hole.

United States Patent 4,373,839 discloses a drill which may be fed axially at a rate approximately twice that of the US Patent 3,963,365 drill. This is because the two cutting blades of the US Patent 4,373,839 drill are positioned so as to cut the entire circumference of the hole during each one-half revolution of the drill. A small diameter core is left between the two blades at the center of the hole but the core is twisted off as the depth of penetration of the drill increases.

Certain embodiments of the drill disclosed in the US Patent 4,373,839 utilize indexable cutting inserts having multiple cutting edges which may be alternately used when a given edge becomes worn. To the best of applicant’s knowledge, drills of this type with indexable cutting inserts have never been marketed commercially. Inserts of the type disclosed in the patent are located so close together along their sides that the portion of the drill body between the inserts cannot be made sufficiently strong to withstand the heavy cutting forces which are imposed on the body by way of the inserts during high speed drilling.

The object of the present invention is to provide a new and improved drill with replaceable cutting inserts of the same general type as disclosed in the US Patent 4,373,839, said drill being able to withstand heavy cutting forces while enjoying the benefits of replaceable cutting inserts.

In order to achieve this objective, the present invention provides a drill in accordance with claim 1.

An advantage of the invention is to achieve the foregoing through the provision of a drill having triangular inserts with uniquely curved cutting edges and with steeply inclined sides which enable the corners of the inserts to be positioned closely adjacent one another while leaving a strong section of drill body between the sides of the inserts.

Another advantage resides in the provision of a novel triangular insert having alternately usable cutting edges each formed with a convexly curved corner position.

These and other characteristic features and advantages of the invention will become more apparent from the following detailed description of a preferred embodiment with reference to the accompanying drawings, wherein:

FIGURE 1 is a perspective view of a new and improved drill incorporating the unique features of the present invention.

FIGURE 1A is an enlarged fragmentary perspective view of the tip end portion of the drill illustrated in FIGURE 1 but showing the drill with one of the inserts removed.

FIGURE 2 is an enlarged fragmentary side elevational view of the drill illustrated in FIGURE 1 and shows the drill forming a hole in a workpiece.

FIGURE 3 is an enlarged end view of the drill.

FIGURE 4 is a perspective view of one of the triangular inserts.

FIGURE 5 is a top plan view of the insert.

FIGURE 6 is a front elevational view of the insert.

FIGURE 7 is an edge view of the insert as seen from the right of FIGURE 6.

FIGURE 8 is an enlarged schematic view showing the inserts drilling a hole.

As shown in the drawings for purposes of illustration, the invention is embodied in a drill 10 for forming a cylindrical hole 11 (FIGURES 2 and 8) in a workpiece 12 made of iron, steel or other metal. The drill comprises an elongated and generally cylindrical body 13 made of high carbon steel and having a tip end 14 and an opposite shank end 15. The shank end of the body is adapted to be clamped in a power-rotated holder (not shown) for effecting rotation of the drill about its own axis A (FIGURE 3), the rotation herein being in a counterclockwise direction as viewed in FIGURES 1 and 3. It will be appreciated that the drill could be held rotationally stationary and that the workpiece could be rotated about the axis of the drill.

Two generally diametrically spaced flutes 16 and 17 are formed in the body and, in this particular instance, extend helically around and along the body from the tip end 14 toward the shank end 15 to enable metal chips to escape from the hole 11. Each flute is generally V-shaped in radial cross-section and is defined by a pair of walls 18 and 19. The wall 18 of each flute faces generally in the direction of rotation while the wall 19 faces gen-
erally opposite to the direction of rotation.

Generally diammeterically spaced pockets 20 and 21 (FIGURES 1A and 3) are formed in the body 13 adjacent the tip end portions of the flutes 16 and 17, respectively, each pocket being formed near the wall 18 of the respective flute. Replaceable cutting inserts 30 and 31 are seated in the pockets 20 and 21, respectively, and act to cut the hole 11 in the workpiece 12 when the drill 10 is rotated counterclockwise about its axis A.

In accordance with the present invention, each of the cutting inserts 30, 31 is generally triangular in shape and is formed with a specially configured corner. As will become apparent subsequently, the use of triangular inserts enables a full circumference of the hole 11 to be cut during each one-half revolution of the drill 10 while permitting the tip end portion of the drill body 13 to be sufficiently strong to withstand heavy cutting forces imposed on the inserts.

More specifically, each of the inserts 30 and 31 is made from a block of tungsten carbide or other suitable cutting material and may be formed by modifying a conventional triangular insert of the type furnished commercially by several insert manufacturers. By way of example only, each insert may, before modification, be a type TNMG-432 insert.

The insert 30 is shown in detail in FIGURES 4 to 7, it being understood that the insert 31 is identical to the insert 30. As shown, the insert 30 is generally in the shape of an equilateral triangle and includes three sides or edge surfaces 33, 34 and 35 of substantially equal length and joining one another at three corners 36, 37 and 38. The three edge surfaces extend between two oppositely facing and generally planar face surfaces 40 and 41. In the original insert prior to modification, all three edge surfaces extend perpendicular to the face surfaces throughout the entire length of each edge surface and thus the original insert itself is of that type which is known in the art as a "negative" insert. Each face surface 40, 41 of each insert is formed with a conventional chip-breaking groove 42 (FIGURES 4 and 6) which is triangular in shape and which is located just inwardly of the periphery of the face surface.

When each insert 30, 31 is properly seated in its respective pocket 20, 21 as shown in FIGURE 3, the face surface 40 of the insert faces in the direction of rotation and defines a cutting face. A cutting edge 45 is defined at the junction of the face surface 40 and the edge surface 34 and, as the cutting edge proceeds from the corner 36 toward the corner 37, it is straight along most of its length as indicated at 46. Upon approaching the corner 37, the cutting edge 45 starts curving convexly and curves convexly out of the plane of the face surface 40 and toward the plane of the face surface 41 as the cutting edge proceeds around the corner. The curved portion 47 of the cutting edge 45 terminates at an inner point 48 (FIGURE 5) located precisely on or just infinitesimally short of a line extending through the axis A and paralleling the straight portion 46 of the cutting edge. From the inner termination point 48 of the curved cutting edge portion 47, the inner edge surface 35 of the insert is dished outwardly as indicated at 49 in FIGURE 5 so as to provide clearance during cutting. No cutting is performed beyond the termination point 48.

Formation of the curved portion 47 of each cutting edge 45 is effected by appropriately grinding the portions of the face surface 40 and the edge surface 35 adjacent the corner 37 of the insert 30, 31. As a result, the corner portion of the face surface 40 and the edge surface 35 are convexly curved as indicated at 50 in FIGURE 4.

The pockets 20 and 21 for the inserts 30 and 31, respectively, each include a flat platform 55 (FIGURE 1A) against which the face 41 of the insert is seated. Two side walls 56 and 57 project from each platform and are angled relative to one another so as to cause the pocket to be formed with a generally V-shaped configuration. When each insert is located in its respective pocket, the edge surfaces 33 and 35 seat against the side walls 56 and 57, respectively, and thus the corner 38 of the insert points toward the shank end 15 of the drill body 30.

A hole 59 (FIGURE 4) is formed through each insert 30, 31 and extends between and perpendicular to the face surfaces 40 and 41 of the insert. To secure the inserts in the pockets 20, 21, a threaded screw or locking pin 60 (FIGURES 2 and 3) extends through each hole 59 and is threaded into a tapped hole 61 (FIGURE 1A) in the platform 55. When the screw is tightened, it clamps the face surface 41 of the insert against the platform 55 and, at the same time, draws the corner 38 of the insert into the corner of the pocket 20, 21 so as to cause the edge surfaces 33 and 35 of the insert to seat tightly against the side walls 56 and 57 of the pocket.

The platform 55 of each pocket 20, 21 is inclined relative to the axis A so as to cause the cutting edge 45 of each insert 30, 31 to be disposed at a negative axial rake angle, meaning that the leading cutting face 40 of the insert is located ahead of the cutting edge 45. As a result, the edge surface 34 of each insert is tipped in such a direction as to define a a clearance face and to avoid rubbing against the bottom of the hole 11 during drilling thereof. In this particular instance, the negative axial rake angle is approximately 10 degrees.
Each insert 30, 31 is also positioned such that its cutting edge 45 is located at a negative radial rake. That is to say, each cutting edge is positioned ahead of the most nearly adjacent radial line that parallels the cutting edge and thus the corner 36 of the insert behind the cutting edge clears the peripheral wall of the hole 11 so as to avoid rubbing against such wall. Herein, each cutting edge is positioned approximately 3.6 mm (0.140") ahead of the aforementioned radial line.

The cutting edge 45 of each insert 30, 31 is also inclined at a lead angle C (FIGURE 2) of about 8 degrees. As a result of the lead angle, the cutting edge 45 slopes toward the shank end 15 of the body 30 as the edge progresses outwardly toward the peripheral wall of the hole 11. This causes the center portion of the hole to be cut somewhat prior to cutting of the peripheral portion and facilitates initial penetration of the drill 10 into the workpiece 12.

With the foregoing arrangement, rotation of the drill 10 causes the cutting edge 45 of each insert 30, 31 to cut across almost a full radius of the hole 11 as is apparent from FIGURE 8. Each cutting edge sweeps around one-half the circumference of the hole during each one-half revolution of the drill and thus the two cutting edges coact to cut the full circumference of the hole every one-half revolution. This enables rapid axial feeding of the drill.

Due to the curved portions 47 of the cutting edges 45, cutting occurs very close to the center of the hole 11. To avoid interference between the inserts 30 and 31, the corners 37 of the two inserts must be spaced from one another and thus a generally cylindrical core 70 (FIGURE 8) is left at the bottom of the hole 11 between the inserts.

The significance of the triangular inserts 30, 31 is most apparent from FIGURE 8. The inserts are positioned and angled such that the corners 37 are spaced very closely together (i.e., a spacing of between 0.5 and 1.0 millimeter) and thus the core 70 is very small in diameter. Accordingly, the core may be easily snapped off by the edge surfaces 35 adjacent the corners or simply fragmented by the tip end 14 of the drill body 13 as the body advances axially. Because the inserts are triangular, the edge surfaces 35 of the two inserts quickly diverge away from one another at a wide angle X of approximately 44 degrees as the edge surfaces progress from the tip end 14 of the drill toward the shank end thereof. Because of the wide divergence of the edge surfaces 35, significant space exists between the edge surfaces for the metal of the drill body 13. Accordingly, the body portion between the edge surfaces 35 may be comparatively thick and rugged to a point closely adjacent the corners 37 so as to impart strength to the body. In spite of the relatively large thickness of the body between the edge surfaces 35 of the triangular inserts, the fact that the edge surfaces converge toward the tip end 14 of the body allows the corners 37 to be located closely adjacent one another so that an easily breakable core 70 of only small diameter is left between the inserts.

Each insert 30, 31 preferably is formed with an alternately usable cutting edge 45' which is formed along the junction of the face surface 41 with the edge surface 33. Other than for location, the cutting edge 45' is identical to the cutting edge 45 and includes straight and curved portions similar to the straight and curved portions 46 and 47 of the cutting edge 45. The straight portion of the cutting edge 45' starts at the corner 36 and extends to a curved portion located at the corner 38. The curved portion of the cutting edge 45' is defined by forming a convexly curved portion 50' (FIGURE 7) on the face 41 of the insert.

After the cutting edge 45 of each insert 30, 31 has become worn, the insert may be removed from the pocket 20, 21. By both inventing and indexing the insert, the cutting edge 45' may be brought into active cutting position. Accordingly, each insert includes two alternately usable cutting edges and thus the insert need not be discarded until both edges have been worn.

From the foregoing, it will be apparent that the present invention brings to the art a new and improved drill 10 with multi-edged indexable inserts 30 and 31 which cut a full circumference of the hole 11 across virtually its full diameter during each one-half revolution of the drill. As a result, the drill may be fed axially at a rapid rate. Because the inserts are triangular, adjacent corners 37 of the inserts may be positioned very close together and yet a thick section of drill body 13 may be located between the inserts near the corners 37 so as to impart strength to the drill body.

Claims

1. A drill (10) with replaceable cutting inserts comprising an elongated and generally cylindrical body (13) having a predetermined longitudinal axis, said body (13) having a tip end portion (14) with an outer periphery, first and second pockets (20, 21) formed in the tip end portion (14) of said body (13) on generally diametrically opposite sides of said axis, and first and second cutting inserts (30, 31) seated respectively within said first and second pockets (20, 21) and removably secured to said body (13), each of said inserts (30, 31) having multiple sides (33, 34, 35) of substantially equal length and each having first and second substantially flat and parallel faces (40, 41) bounded by said sides (33, 34, 35), there be-
ing a corner (36, 37, 38) at the junction of each side of each insert with each adjacent side, one side (34) of each insert (30, 31) having a cutting edge (45) extending transversely of the body (13) adjacent the tip (14) thereof from a first corner (36) located outwardly of said outer periphery to a second corner (37) located short of said axis, each cutting edge (45) being straight (46) upon proceeding from said first corner toward said second corner and curling convexly (47) out of the plane of said first face (40) and toward the plane of said second face (41) upon approaching said second corner (37), said drill (10) being characterized in that each of said inserts (30, 31) is generally triangular and consists of three sides (33, 34, 35) and three corners (36, 37, 38), each of said pockets (20, 21) being generally V-shaped and having a pair of sides (56, 57) which are both inclined relative to said axis and which embrace two sides (33, 35) of the respective triangular insert (30, 31), each triangular insert (30, 31) having said cutting edge (45) defined at the junction of said third side (34) with said first face (40), each insert (30, 31) including an alternately usable cutting edge (45') extending from said first corner (36) to said third corner (38) and defined along the junction of said second face (41) with another of said sides (33) of said insert, said alternately usable cutting edge (45') having a straight portion (46') extending from said first corner (36) and having a convexly curved portion (47') adjacent said third corner (38).

2. The drill as claimed in Claim 1 characterized in that the curved portion (47) of the cutting edge (45) of each insert (30, 31) terminates short of the plane of said second face (41).

3. The drill as claimed in Claim 2 characterized in that the curved portion (47) of the cutting edge (45) of each insert (30, 31) terminates on or just short of a straight line extending through said longitudinal axis and being parallel to the straight portion (46) of the cutting edge (45).

4. The drill as claimed in any one of the Claims 1 to 3 characterized by first and second flutes (16, 17) formed in said body (13) on generally opposite sides thereof and extending from said tip end portion (14) toward said shank end portion (15), each of said flutes (16, 17) being generally V-shaped in radial cross-section and each being defined by a pair of walls (18, 19), said first pocket (20) being formed adjacent one wall (18) of said first flute (16), said second pocket (21) being formed adjacent the corresponding wall (18) of said second flute (17), each of said pockets (20, 21) being defined by a platform (55) facing in the direction of rotation of said body (13), said sides (56, 57) extending from said platform (55), the apex of the V of each pocket (20, 21) pointing toward the shank end portion (15) of said body (13), one face (41) of each insert (30, 31) being seated against the platform (55) of the respective pocket (20, 21), the opposite face (40) of each insert (30, 31) facing in the direction of rotation of said body (13) and defining a cutting face, the cutting face (40) of each insert (30, 31) being generally flat but being convexly curved toward said platform (55), adjacent said second corner (37) so as to cause said cutting edge (45) to curve convexly (47).

**Patentansprüche**

1. Bohrer (10) mit auswechselbaren Schneideinsätzen, mit einem länglichen und im allgemeinen zylindrischen Schaft (13) der eine vorgegebene Längsschase aufweist, wobei der Bohrerschaft (13) einen Bohrerspitzebereich (14) mit einem äußeren Umris umfasst, erste und zweite Taschen (20, 21) im Bohrerspitzebereich (14) des Schaftes (13) im allgemeinen an bezüglich der Achse einander diametral gegenüberliegenden Seiten, erste und zweite Schneideinsätze (30, 31) welche bzw. in den ersten und zweiten Taschen (20, 21) sitzen und abnehmbar am Schaft (13) befestigt sind, wobei jeder Schneideinsatz (30, 31) mehrfache Randflächen (33, 34, 35) von etwa gleicher Länge und eine erste und eine zweite hauptsächlich flache und parallele von den Randflächen (33, 34, 35) begrenzte Grundflächen (40, 41) aufweist, mit einer Ecke (36, 37, 38) an der Verbindung jeder Randfläche des Einsatzes mit der nächsten Randfläche, wobei eine Randfläche (34) jedes Einsatzes (30, 31) eine Schneckkante (45) aufweist, welche sich transversal zum Schaft (13) in der Nähe der Schaftspitze (14) von einer ersten Ecke (38) welche sich ausserhalb des Umrisse befindet zu einer zweiten Ecke (37) dicht an der Achse erstreckt, wobei jede Schneckkante (45) von einer ersten Ecke in Richtung zweite Ecke geradlinig (46) ist und beim Annähern der zweiten Ecke (37) konvex aus der Ebene der ersten Grundfläche (40) gegen die Ebenen der zweiten Grundfläche (41) gekrönt (47) ist, wobei der Bohrer (10) dadurch gekennzeichnet ist, dass jeder Einsatz (30, 31) im allgemeinen dreieckig ist und aus den drei Randflächen (33, 34, 35) und drei Ecken (36, 37, 38) besteht, dass jede Tasche (20, 21) im allgemei-
nen V-förmig ist mit einem Paar Seitenflächen (56, 57) welche beide gegenüber der Achse geneigt sind und welche jeweils zwei Seiten (33, 35) eines jeweiligen dreieckigen Einsatizes (30, 31) umgeben, dass jeder dreieckige Ein-
satz (30, 31) seine Schneidkante (45) an der Verbindung der dritten Randfläche (34) mit der ersten Grundfläche (40) hat, dass jeder Einsatz (30, 31) eine abwechselnd benutzbare Schneidkante (45') aufweist, welche sich von der ersten Ecke (36) bis zur dritten Ecke (38) erstreckt und entlang der Verbindung der zweiten Grundfläche (41) mit einer anderen Rand-
fläche (33) des Einsatzes gebildet ist, dass die abwechselnd benutzbare Schneidkante (45') ei-
en geradlinigen Bereich (46') ausgehend von der ersten Ecke (36) und in der Nähe der dritten Ecke (38) einen konvexen bogenförmigen Bereich (47') aufweist.
2. Bohrer nach Anspruch 1, dadurch gekenn-
zeichnet, dass der bogenförmige Bereich (47) der Schneidkante (45) jedes Einsatzes (30, 31) kurz vor der Ebene der zweiten Grundfläche (41) endet.
3. Bohrer nach Anspruch 2, dadurch gekenn-
zeichnet, dass der bogenförmige Bereich (47) der Schneidkante (45) jedes Einsatzes (30, 31) auf oder kurz vor einer Geraden endet, welche durch die Längsachse verläuft und parallel zum geradlinigen Bereich (46) der Schneidkante (45) ist.
4. Bohrer nach einem der Ansprüche 1 bis 3, gekennzeichnet durch erste und zweite Bohrer-
uten (16, 17) welche im allgemeinen auf ge-
genüberliegenden Seiten des Bohrerschaftes (13) gebildet sind und welche sich vom Boh-
nerspitzebereich (14) in Richtung Schaftende (15) erstrecken , wobei jede Bohrnut (16, 17) in radialem Querschnitt im allgemeinen V-förm-
ig ist und durch ein Paar Seitenwände (18, 19) begrenzt ist, wobei die erste Tasche (20) neben der Seitenwand (18) der ersten Bohr-
nut (16) und die zweite Tasche (21) neben der entsprechenden Seitenwand (18) der zweiten Bohrnut (17) gebildet , wobei jede Tasche (20, 21) von einer in Drehrichtung des Bohrer-
schaftes (13) zeigenden Stützfläche (55) gebil-
det wird und dass die Seitenflächen (56, 57) sich von dieser Stützfläche (55) erstrecken, wobei die Spitze der V-Form jeder Tasche (20, 21) in Richtung Endbereich (15) des Bohrer-
schaftes (13) zeigt, wobei eine Grundfläche (41) jedes Einsatzes (30, 31) auf der Stützfläche (55) der entsprechenden Tasche (20, 21) sitzt und die gegenüberliegende Grundfläche (40) jedes Einsatzes (30, 31) in Drehrichtung des Bohrerschaftes (13) gerichtet ist und eine Schnittfläche (40) bildet, wobei die Schnittflä-
che (40) jedes Einsatzes (30, 31) im allgemei-
nen eben jedoch in der Nähe der zweiten Ecke (37) zur Stützfläche (55) hin konvex gekrümm-
it, so dass die Schneidkante (45) einen konve-
xen bogenförmigen Verlauf (47) hat.

Revendications

1. Foret (10) à plaquettes de coupe remplaçables comprenant un corps (13) allongé et globale-
ment cylindrique ayant un axe longitudinal pré-
déterminé, ledit corps (13) ayant une portion de pointe (14) avec un pourtour périphérique, des premiers et seconds logements (20, 21) formés dans la portion de pointe (14) du corps (13) à des endroits en général diamétralement opposés par rapport audit axe et des première-
res et secondes plaquettes de coupe (30, 31) disposées respectivement dans les premiers et
seconds logements (20, 21) et attachées de
manièreméntable audit corps (13), chacune desdites plaquettes (30, 31) ayant de multiples côtés (33, 34, 35) sensiblement de même lon-
gueur et chacune ayant une première et se-
conde face (41, 42) sensiblement planes et
parallèlentournées par ledits côtés (33, 34, 35), un coin (36, 37, 38) se trouvent à
la jonction de chaque côté de la plaquette avec
chaque côté adjacent, un côté (34) de chaque
plaquette (30, 31) ayant un bord de coupe (45) s'étendant transversalement par rapport au corps (13) à proximité de la pointe (14)
depuis un premier coin (36) situé à l'extérieur
dudit pourtour périphérique vers un second
coin (37) à proximité immédiate dudit axe,
chaque bord de coupe (45) étant rectiligne (46)
en s'étendant dudit premier coin vers ledit
second coin et présentant une courbure
convexe (47) hors du plan de ladite première
face (40) à l'approche dudit second coin (37)
vers le plan de ladite seconde face (41), ledit
foret étant caractérisé en ce que chacune des
dites plaquettes (30, 31) est en général trian-
gulaire avec trois côtés (33, 34, 35) et trois
coins (36, 37, 38) chacun desdits logements
(20, 21) étant en général en forme de V avec
une paire de parois latérales (56, 57) qui sont
toutes les deux inclinées par rapport audit axe
et qui contiennent deux côtés (33, 35) de
la plaquette triangulaire respective (30, 31), cha-
que plaquette triangulaire (30, 31) ayant ledit
bord de coupe (45) défini à la jonction dudit
troisième côté (34) avec ladite première
face (40), chaque plaquette (30, 31) comprenant un
bord de coupe de réserve (45) s'étendant
dudit premier coin (36) vers ledit troisième coin (38) et défini le long de la jonction de ladite seconde face (41) avec un autre desdits côtés (33) de ladite plaquette, ce bord de coupe de réserve (45°) ayant des portions rectilignes (46°) s'étendant à partir dudit premier coin (36) avec une portion à courbure convexe (47°) du côté dudit troisième coin (38).

2. Foret selon la revendication 1, caractérisé en ce que la portion courbe (47) du bord de coupe (45) de chaque plaquette (30, 31) se termine juste devant le plan de ladite seconde face (41).

3. Foret selon la revendication 2, caractérisé en ce que la portion courbe (47) du bord de coupe (45) de chaque plaquette (30, 31) se termine sur ou juste devant une ligne droite s'étendant à travers ledit axe longitudinal parallèlement à la portion rectiligne (46) du bord de coupe (45).

4. Foret selon l'une quelconque des revendications 1 à 3, caractérisé par une première et une seconde cannelure (16, 17) formées dans ledit corps (13) sur des côtés opposés et s'étendant de la portion de pointe (14) en direction de la portion de talon (15), chacune desdites cannelures (16, 17) étant, en général, en coupe radiale, en forme de V et chacune étant définie par une paire de parois (18, 19), ledit premier logement (20) étant formé près d'une paroi (18) de ladite première cannelure (16), ledit second logement (21) étant formé près de la paroi correspondante (18) de ladite seconde cannelure (17), chacun desdits logements (20, 21) étant défini par un fond (55) orienté dans la direction de rotation dudit corps (13), lesdites parois (56, 57) s'étendant dudit fond (55), la pointe du (V) de chaque logement (20, 21) étant dirigée vers la portion de talon (15) dudit corps (13), une face (41) de chaque plaquette (30, 31) étant en appui contre le fond (55) du logement respectif (20, 21), la face opposée (40) de chaque plaquette (30, 31) étant orientée dans le sens de rotation dudit corps (13) et définissant une face de coupe, la face de coupe (40) de chaque plaquette (30, 31) étant, en général, plane mais avec une courbure convexe en direction du fond (55) du côté du second coin (37) de manière à conférer au bord de coupe (45) une courbure convexe (47).
