Description

[0001] The present invention generally relates to trunk line identification systems, and more particularly to a trunk line identification system which is applied to a communication from a first station to a second station via a third station.

[0002] FIG.1 generally shows an example of a conventional communication system. A station "A" is coupled to a station "B" via a transmission line 3, and the station "B" is coupled to a station "C" via a transmission line 4. Each of the stations "A", "B" and "C" have a switching system 1 and a transmitting apparatus 2. For example, each transmitting apparatus 2 comprises a pulse code modulation (PCM) signal of 64 kbps into 32 kbps by an adaptive differential pulse code modulation (ADPCM) coding scheme and transmits the compressed signal on the transmission line 3 or 4.

[0003] Among the signals transmitted from the station "A" to the station "B", there are signals which are to be dropped to a subscriber 5 within the station "B" and signals which are to be transmitted to the station "C" via the station "B".

[0004] According to the conventional communication system, the transmitting apparatus 2 multiplexes signals amounting to a plurality of channels (for example, 24 channels in the case of PCM 24 system) and simply transmits the multiplexed signal on the line. Hence, there is no function of judging whether the signal received from the station "A" via the transmission line 3 is to be dropped at the station "B" or relayed to the station "C" via the transmission line 4. For this reason, the transmitting apparatus 2 of the station "B" must once decode the compressed signal back into the original PCM signal, and the switching system 1 of the station "B" judges whether the PCM signal is to be dropped at the station "B" or relayed to the station "C" via the transmission line 4. If the PCM signal is to be dropped at the station "B", the PCM signal is dropped to the subscriber 5. But if the PCM signal is to be relayed to the station "C", the PCM signal is first returned to the transmitting apparatus 1 of the station "B" so as to be compressed again, and the compressed signal is then transmitted to the station "C" via the transmission line 4. As a result, the signal from the station "A" is relayed by the station "B" and transmitted to the station "C".

[0005] As described above, the switching system 1 of the relay station "B" must also receive the signal which is unrelated to the station "B", that is, the signal which is simply to be relayed to the station "C". Hence, the number of lines to the transmission line must be reserved by taking into account such traffic of signals.

[0006] In the case of high-speed digital lines and integrated services digital networks (ISDNs), the transmission is generally made at 32 kbps or 16 kbps per voice grade line using the voice compression technique. In these cases, a voice compression circuit is provided in the transmitting apparatus 2 in a connection channel to the switching system 1, so that the voice compression is carried out prior to transmission to the transmission line. However, the signal which is simply to be relayed by the relay station "B" is also passed through such a voice compression circuit when connecting to the switching system 1 of the relay station "B", although the signal which is to be relayed by the relay station "B" originally does not need to be subjected to the voice compression. On the other hand, in the case where the voice signal has a relatively low bit rate which is less than 16 kbps, the voice signal is subjected to a predetermined voice signal processing other than the voice compression.

[0007] In other words, because the switching system 11 processes each voice grade line at 64 kbps, the necessary switching cannot be made if the signals are in the form of the compressed voice signals. Accordingly, even if the compressed voice signals are simply to be relayed at the relay station "B", the compressed voice signals must first be expanded back to the voice signals in order to perform the necessary switching. As a result, there are problems in that an unnecessary voice signal processing circuit must be provided, a signal delay is increased by the provision of the voice signal processing circuit, and the system design becomes complex.

[0008] JP-A-63 172 555 shows a single exchange providing the function of both a terminal station exchange and a relay exchange. The terminal station exchange converts the coded transmitted information into voice signals, while the relay exchange function passes on the coded information without performing decoding. The coded information includes identifying information used as a basis for call switching to selectively provide a substitute answer service or a transfer service.

[0009] GB-A-2 066 624 discusses generating communication path identity signals in a time division switching system comprising a plurality of communication units. A receiver for identifying the communication path identity signals and completing a communication path accordingly is also disclosed.

[0010] Lastly, reference is made to JP-A-60 263 555, which discloses a trunk line identifying system comprising a line switch part (trunk exchange) connected to each of a plurality of channels respectively connected to corresponding transmission lines to respective subscriber stations, signal processing elements, coupled to the line switch part, for processing signals containing identification information received from one of the transmission lines and transmitted to another of the transmission lines, via the line switch part, and a switching system (subscriber exchange), connected to the signal process parts, for switching those signals based on that identification information.

[0011] It is a general object of the present invention to provide a novel and useful trunk line identification system in which it is possible to efficiently recognize whether a signal is to drop at the station or to simply be relayed to another station to form a trunk connection.
[0012] According to the invention there is provided a trunk line identification system for forming a trunk connection of (i) a first transmission line to a first station of a local subscriber with (ii) a second transmission line to a second station, the system comprising, a line switch part connected to each of a plurality of channels, a first one of which is for connection to said first transmission line and a second one of which is for connection to said second transmission line, channel processing parts respectively associated with said channels, said channel processing parts being coupled to said line switch part, for processing signals received from and transmitted to the first and second transmission lines via said line switch part, and each including first and second means, said line switch part being arranged to connect each channel with its corresponding channel processing parts, and a switching system, connected to said channel processing parts, selectively operable for relaying a signal received by a first channel processing part from the first channel via said line switch part to the second channel line via said switching system and a second channel processing part or for dropping said received signal, via said switching system, to a subscriber connected to said switching system, and said first means of the second channel processing part being arranged to transmit an identification signal to the first channel processing part via said switching system when the signal received by the first channel processing part is to be relayed, and said second means of the first channel processing part being arranged to judge whether or not a line is being used as a trunk line based on whether the identification signal is detected, said line switch part being arranged to form said trunk connection between first and second channels via said first and second channel processing parts when the identification signal is detected and to drop said received signal when no identification signal is detected.

[0013] In a preferred embodiment, each channel processing part includes signal processing means for subjecting a signal received from and transmitted to the associated channel via said line switch part to a predetermined signal processing, and there may be further provided signal processing control means, coupled to each of the channel processing parts, for controlling the signal processing means of each of the channel processing parts based on outputs of each of the channel processing parts, so that the signal processing control means bypasses the predetermined signal processing in the first and second channel processing parts when the first channel processing part detects the identification signal from the first means of the second channel processing part.

[0014] According to the trunk line identification system to be described below, it is possible to prevent unnecessary signal processing when the received signal is simply to be relayed and not dropped.

[0015] The invention will be better understood by referring, by way of example, to the accompanying drawings, in which:

Fig. 1 is a system block diagram generally showing an example of a conventional communication system;
Fig. 2 is a system block diagram for explaining the operating principle of a first embodiment of a trunk line identification system according to the present invention;
Fig. 3 is a system block diagram for explaining the operating principle of a second embodiment of the trunk line identification system according to the present invention;
Fig. 4 is a system block diagram generally showing a communication system to which the present invention is applied;
Fig. 5 is a system block diagram showing an essential part of the first embodiment;
Fig. 6 shows the state of the connection at each part of the first embodiment for explaining one operation thereof;
Fig. 7 shows the state of the connection at each part of the first embodiment for explaining another operation thereof;
Fig. 8 is a system block diagram showing an essential part of the second embodiment; and
Fig. 9 is a system block diagram showing an embodiment of a signal processing part shown in Fig. 8.

[0016] First, a description will be given of the operating principles of first and second embodiments of the trunk line identification system according to the present invention, by referring to FIGS. 2 and 3. FIG. 2 shows a block system for explaining the operating principle of the first embodiment, and FIG. 3 shows a block system for explaining the operating principle of the second embodiment. In FIGS. 2 and 3, those parts which are the same as those corresponding parts in FIG. 1 are designated by the same reference numerals.

[0017] In FIG 2, a plurality of channel processing parts 20 are coupled between the switching system 1 and a line switch part 10. The line switch part 10 and the channel processing parts 20 are included within the transmitting apparatus 2. A line switch control part 30 is coupled between the channel processing parts 20 and the line switch part 10. This line switch control part 30 controls the switching of the line switch part 10 in response to control signals output from the channel processing parts 20. The subscriber 5 is coupled to the switching system 1.

[0018] A transmission data signal SD, a reception data signal RD, a signal transmission signal SS and a signal reception signal SR are transmitted between the switching system 1 and the transmitting apparatus 2 via signal lines which are independent from the data signal lines.

[0019] When connecting to the communication line,
an identification signal is transmitted from the channel processing part 20 of the first station in a direction opposite to the connecting direction of the call. If this communication line is to drop to the first station to which the channel processing part 20 belongs, the identification signal will not reach the channel processing part 20 of the second station at the other end. In addition, if this communication line is a trunk line, the switching system 1 of the first station internally relays this line, and the identification signal will reach the channel processing part 20 of the second station at the other end. Accordingly, it is possible to efficiently recognize at the transmitting apparatus 2 of the first station whether the signal is to drop to the first station or the signal is to be relayed via the first station. If the communication line is used simply for relaying the signal, the line switch control part 30 controls the line switch part 10 in the first station to loop back the line without passing the signal via the switching system 1 of the first station.

[0020] In FIG. 3, those parts which are the same as those corresponding parts in FIG. 2 are designated by the same reference numerals, and a description thereof will be omitted. In FIG. 3, a signal processing control part 40 carries out a signal process based on output control signals of the channel processing parts 20, and supplies signals to the line switch part 10 and each of the channel processing parts 20.

[0021] When connecting to the communication line, an identification signal is transmitted from the channel processing part 20 of the first station in a direction opposite to the connecting direction of the call. If this communication line is to drop to the first station to which the channel processing part 20 belongs, the identification signal will not reach the channel processing part 20 of the second station at the other end. In addition, if this communication line is a trunk line, the switching system 1 of the first station internally relays this line, and the identification signal will reach the channel processing part 20 of the second station at the other end. Accordingly, it is possible to efficiently recognize at the transmitting apparatus 2 of the first station whether the signal is to drop to the first station or the signal is to be relayed via the first station. If the communication line is used simply for relaying the signal, it is sufficient to simply switch the line, and the signal processing control part 40 changes the signal processing system so as not to carry out a voice compression which is originally unnecessary.

[0022] Therefore, as may be understood from the operating principles of the first and second embodiments, the present invention does not require the unnecessary voice compression and there is no need to provide an additional voice processing circuit.

[0023] FIG. 4 generally shows a communication system to which the present invention is applied. It is assumed for the sake of convenience that a signal is transmitted from a station “A” to a station “C” via a relay station “B”. In this case, at the transmitting apparatus 2 of the relay station “B”, a connection is made from a channel CH1 to a channel CH2 by a cell, and the signal is transmitted in a loop indicated by a bold line. In the case of the trunk line, the signal is always looped back by the switching system 1 of the relay station “B” as shown. Accordingly, when an identification signal is transmitted from the channel CH2 to the channel CH1 as indicated by a thin line, that is, in a direction opposite to the connecting direction of the call, this identification signal is transmitted from the channel CH2 to the channel CH1 because the switching system 1 of the relay station “B” is connected as shown. But if the line is to drop to the relay station “B”, the looping back connection shown does not exist, and the identification signal will not be transmitted from the channel CH2 to the channel CH1. Hence, it is possible to identify the trunk line by detecting whether or not the identification signal is received at the channel CH1.

[0024] Next, a more detailed description will be given of the first embodiment, by referring to FIG. 5. In FIG. 5, those parts which are the same as those corresponding parts in FIG. 2 are designated by the same reference numerals, and a description thereof will be omitted.

[0025] In FIG. 5, those parts other than the switching system 1 form the transmitting apparatus 2 shown in FIG. 4. A channel interface 21 connects the transmitting apparatus 2 and the switching system 1. A SS detector 22 detects a signal SS from a SS line. A pattern generator 23 is started by the SS detector 22. A pattern check part 24 checks the data pattern of the transmitting data which is received via a SD line. For example, the pattern generator 23 includes a read only memory (ROM) which generates a fixed pattern, and the pattern check part 24 includes a comparator for checking the pattern by comparison.

[0026] A SR detector 25 detects a signal SR, and an output of this SR detector 25 starts the pattern check part 24. A signal processing part 26 is connected to SD and SR lines, and a switch SW1 is inserted at an intermediate part of a RD line. A contact a of the switch SW1 is connected to the RD line, and a contact b of this switch SW1 is connected to the pattern generator 23. The switch SW1 is controlled by an output of the SS detector 22. Another switch SW2 is controlled by an output of the SR detector 25. The line switch control part 30 receives the output of the pattern check part of each of the channel processing parts 20 and controls the connection of the line switch part 10. The subscriber 5 is connected to the switching system (voice line switch) 1.

[0027] Next, a more detailed description will be given of the operation of the first embodiment, by referring to FIG. 5. It will be assumed for the sake of convenience that the line is connected from the station “A” to the station “C” via the relay station “B” as in the case shown in FIG. 4 described above. In addition, it will be assumed that the connecting direction of the call at the relay station “B” is from the channel CH1 to the channel CH2 as indicated by an arrow L1.
[0028] First, the signal SR becomes ON on the side of the channel CH1. On the side of the channel CH2, the signal SS becomes ON. FIG.6 shows the state of the connection at each part of the first embodiment. The SR line of the channel CH1 and the SS line of the channel CH2 become connected, and the signal SS of the channel CH2 becomes ON when the signal SR of the channel CH1 becomes ON. In this state, when the SS detector 22 detects the signal SS of the channel CH2, the pattern generator 23 of the CH2 processing part 20 is started and an identification signal is output therefrom. For example, the identification signal output from the pattern generator 23 indicates the channel CH2. The identification signal is supplied to the line switch control part 30.

[0029] Next, when the signal SR of the channel CH1 becomes ON, the SR detector 25 of the CH1 processing part 20 detects this signal SR and turns the switch SW2 OFF and also starts the pattern check part 24. In FIGS. 5 and 6, a dotted line indicates the connection in the OFF state of the switch SW2. On the other hand, on the side of the channel CH2, the signal SS becomes ON and the SS detector 22 detects this signal SS. Hence, the pattern generator 23 is started, and at the same time, the common contact of the switch SW1 is switched over and connected to the contact b from the contact a.

[0030] Accordingly, the identification signal which is generated from the pattern generator 23 of the CH2 processing part 20 passes through the switching system 1 in a direction opposite to the connecting direction of the call. In other words, the identification signal passes the RD line of the channel CH2 and reaches the pattern check part 24 of the CH1 processing part 20 via the SD line of the channel CH1. The pattern check part 24 of the CH1 processing part 20 recognizes the identification signal from the channel CH2. As a result, it is possible to recognize that the communication line is a trunk line. If the communication line is to drop to the relay station "B", the identification signal will not be connected within the switching system 1 as shown in FIG.6, and the identification signal will not be transmitted to the side of the channel CH1.

[0031] FIG.7 shows the state of the connection at each part of the first embodiment, for explaining another operation thereof. When it is detected in the case shown in FIG.6 that the channel CH1 is connected to the channel CH2 by the call, the signal from the pattern check part 24 of the CH1 processing part 20 and the signal from the pattern generator 23 of the CH2 processing part 20 are supplied to the line switch control part 30. When the line switch control part 30 receives these signals, the line switch control part 30 recognizes that the communication line is a trunk line, and instructs the line switch part 10 to connect from the channel CH1 to the channel CH2. For example, the line switch part 10 is made up of a timing switch.

[0032] Accordingly, the line switch part 10 connects the channel CH1 to the channel CH2, and it is possible to realize the path setting which is carried out within the switching system 1 in the case shown in FIG.6 on the side of the line switch part 10 in the case shown in FIG.7. As a result, the setting of the path in the switching system 1 is released, and the load on the switching system 1 is reduced by this operation.

[0033] Next, a more detailed description will be given of the second embodiment, by referring to FIG.8. In FIG. 8, those parts which are the same as those corresponding parts in FIGS. 3 and 5 are designated by the same reference numerals, and a description thereof will be omitted.

[0034] In FIG.8, the signal processing control part 40 receives a signal from the pattern check part 24 of each of the channel processing parts 20 and changes the signal processing. The output of the signal processing control part 40 is supplied to the line switch part 10 and the signal processing part 26 of each of the channel processing parts 20. Otherwise, the construction shown in FIG.8 is the same as that shown in FIG.5.

[0035] In this second embodiment, the operation is the same as that of the first embodiment described in conjunction with FIG.5 up to the procedure which judges that the communication line is a trunk line from the channel CH1 to the channel CH2. That is, the signal SR on the side of the channel CH1 becomes ON, and the signal SS on the side of the channel CH2 becomes ON. FIG. 6 shows the state of the connection at each part of this embodiment. When the signal SR on the side of the channel CH1 becomes ON, the signal SS on the side of the channel CH2 becomes ON. When the SS detector 22 of the CH2 processing part 20 detects the signal SS of the channel CH2 which is ON, the pattern generator 23 of the CH2 processing part 20 is started by the output of the SS detector 22 of the CH2 processing part 20, and the pattern generator 23 of the CH2 processing part 20 outputs an identification signal. The identification signal output from the pattern generator 23 of the CH2 processing part 20 indicates the channel CH2, and this identification signal is supplied to the signal processing control part 40.

[0036] Next, when the signal SR of the channel CH1 becomes ON, the SR detector 25 of the CH1 processing part 20 detects this signal SR and turns the switch SW2 OFF and also starts the pattern check part 24. On the other hand, on the side of the channel CH2, the signal SS becomes ON and the SS detector 22 detects this signal SS. Hence, on the side of the channel CH2, the SS detector 22 starts the pattern generator 23 and switches over the common contact of the switch SW1 to the contact b from the contact a.

[0037] Therefore, the identification signal which is generated from the pattern generator 23 on the side of the channel CH2 passes through the switching system 1 in a direction opposite to the connecting direction of the call. In other words, the identification signal passes the RD line of the channel CH2 and reaches the pattern check part 24 of the CH1 processing part 20 via the SD line of the channel CH1.
line of the channel CH1. The pattern check part 24 of the CH1 processing part 20 recognizes the identification signal from the channel CH2.

[0038] The pattern check part 24 of the CH1 processing part 20 supplies connection information between the channels CH1 and CH2 to the signal processing control part 40. The signal processing control part 40 instructs the change of the signal processing to the signal processing parts 26 of the channels CH1 and CH2 in response to the connection information, that is, the channel combination. As a result, the signal processing parts 26 of the CH1 and CH2 processing parts 20 change the signal processing. Accordingly, it is possible to simplify the signal processing because it is unnecessary to convert the compressed voice signal into the voice signal if the relay station "B" only needs to relay the compressed voice signal.

[0039] FIG.9 shows an embodiment of the signal processing part 26 shown in FIG.8. In FIG.9, the signal processing part 26 includes an encoder 261, a decoder 262, a bypass circuit 263, and switches 264 and 265 which are connected as shown. The switch 264 is connected to the switching system 1, and the switch 265 is connected to the line switch part 10. The switches 264 and 265 are linked and controlled by the signal from the signal processing control part 40, so that the signal to or from the transmission line passes through the encoder 261 or the decoder 262 in one mode and the bypass circuit 263 bypasses the encoder 261 and the decoder 262 in another mode. In other words, the signal processing can be changed between the two modes.

[0040] Reference signs in the claims are intended for better understanding and shall not limit the scope.

Claims

1. A trunk line identification system for forming a trunk connection of (i) a first transmission line to a first station of a local subscriber with (ii) a second transmission line to a second station, the system comprising, a line switch part (10) connected to each of a plurality of channels, a first one of which is for connection to said first transmission line and a second one of which is for connection to said second transmission line, channel processing parts (20) respectively associated with said channels, said channel processing parts (20) being coupled to said line switch part (10), for processing signals received from and transmitted to the first and second transmission lines via said line switch part (10), and each including first and second means (23, 24), said line switch part (10) being arranged to connect each channel with its corresponding channel processing parts, and a switching system (1), connected to said channel processing parts (20), selectively operable for relaying a signal received by a first channel processing part (20) from the first channel via said line switch part (10) to the second channel line via said switching system (1) and a second channel processing part (20) or for dropping said received signal, via said switching system, to a subscriber connected to said switching system (1), and said first means (23) of the second channel processing part (20) being arranged to transmit an identification signal to the first channel processing part (20) via said switching system (1) when the signal received by the first channel processing part (20) is to be relayed, and said second means (24) of the first channel processing part (20) being arranged to judge whether or not a line is being used as a trunk line based on whether the identification signal is detected, said line switch part (10) being arranged to form said trunk connection between first and second channels via said first and second channel processing parts when the identification signal is detected and to drop said received signal when no identification signal is detected.

2. The trunk line identification system as claimed in claim 1, characterized in that said first means (23) of second channel processing part (20) is arranged to generate the identification signal which indicates the second channel.

3. The trunk line identification system as claimed in claim 1 or 2, characterized in that said first means (23) of said channel processing parts (20) are arranged to transmit the identification signal to said switching system (1) in a direction opposite to a connecting direction of a call.

4. The trunk line identification system as claimed in any one of claims 1 to 3, characterized in that said switching system (1) is arranged to form a loop back path, which connects the first and second channel processing parts (20) only when the signal received from the first channel is to be relayed.

5. The trunk line identification system as claimed in any one of claims 1 to 4, characterized in that there is further provided line switch control means (30), coupled to each of said channel processing parts (20), for controlling a connection of said line switch part (10) to the second channel.

6. The trunk line identification system as claimed in any one of claims 1 to 4, characterized in that each channel processing part (20) includes signal processing means (28) for subjecting a signal received from and transmitted to the associated channel via said line switch part (10) to a predetermined signal processing.

7. The trunk line identification system as claimed in claim 6, characterized in that there is further provid-
ed signal processing control means (40), coupled to each of said channel processing parts (20), for controlling said signal processing means (26) of each of the channel processing parts (20) based on outputs of each of said channel processing parts, said signal processing control means (40) bypassing the predetermined signal processing in said first and second channel processing parts when the first channel processing part detects the identification signal from the first means (23) of the second channel processing part.

8. A trunk line identification system according to any preceding claim and having its first and second channels respectively connected, via transmission lines, to first and second stations (A, C) as afore-
said.

Patentansprüche

1. Verbindungsleitung-Identifikationssystem zur Bildung einer Fernverbindung aus (i) einer ersten Übertragungsleitung zu einer ersten Station eines lokalen Teilnehmers mit (ii) einer zweiten Übertragungsleitung zu einer zweiten Station, wobei das System umfasst: ein Leitungsvermittlungsteil (10), welches mit einer Vielzahl von Kanälen verbunden ist, wovon ein erster der Verbindung mit der ersten Übertragungsleitung dient und wovon ein zweiter der Verbindung mit der zweiten Übertragungsleitung dient, Kanalverarbeitungssteile (20), welche jeweils mit den Kanälen in Beziehung stehen, wobei die Kanalverarbeitungssteile (20) mit dem Leitungsvermittlungsteil (10) gekoppelt sind, um Signale, welche aus den ersten Übertragungsleitungen über das Leitungsvermittlungsteil (10) empfangen werden bzw. dahin übertragen werden zu verarbeiten, und welche jeweils erste und zweite Einrichtungen (23, 24) enthalten, wobei das Leitungsvermittlungsteil (10) angeordnet ist, jeden Kanal mit seinem entsprechenden Kanalverarbeitungssteil zu verbinden, und ein Vermittlungssystem (1), welches verbunden ist mit den Kanalverarbeitungssteilen (20), selektiv betreibbar zur Weitergabe eines Signals, welches empfangen wird durch ein erstes Kanalverarbeitungssteil (20) aus dem ersten Kanal über das Leitungsvermittlungsteil (10), an die zweite Kanalverarbeitung über das Vermittlungssystem (1) und ein zweites Kanalverarbeitungs teil (20), oder zum Abgeben des empfangenen Signals, über das Vermittlungssystem, an einen Teilnehmer, welcher mit dem Vermittlungssystem (1) verbunden ist, und wobei die erste Einrichtung (23) des zweiten Kanalverarbeitungssteils (20) angeordnet ist ein Identifikationsignal an das erste Kanalverarbeitungssteil (20) über das Vermittlungssystem (1) zu übertragen, wenn das von dem ersten Kanalverarbeitungssteil (20) empfangene Signal weitergegeben werden soll, und die zweite Einrichtung (24) des ersten Kanalverarbeitungssteils (20) angeordnet ist zu beurteilen, ob oder ob nicht eine Leitung als Verbindungsleitung verwendet wird, auf der Grundlage, ob das Identifikationsignal erfasst wird, wobei das Leitungsvermittlungsteil (10) angeordnet ist, eine Fernverbindung zwischen ersten und zweiten Kanälen über die ersten und zweiten Kanalverarbeitungssteile zu bilden, wenn das Identifikationsignal erfasst wird, und das empfangene Signal abzugeben, wenn kein Identifikationsignal erfasst wird.

2. Verbindungsleitung-Identifikationssystem nach Anspruch 1, dadurch gekennzeichnet, dass die erste Einrichtung (23) des zweiten Kanalverarbeitungssteils (20) angeordnet ist, das Identifikationsignal zu erzeugen, welches den zweiten Kanal anzeigt.

3. Verbindungsleitung-Identifikationssystem nach Anspruch 1 oder 2, dadurch gekennzeichnet, dass die erste Einrichtung (23) der Kanalverarbeitungssteile (20) angeordnet ist, das Identifikationsignal an das Vermittlungssystem (1) in eine zur Verbindungsrichtung eines Anrufs entgegengesetzte Richtung zu übertragen.

4. Verbindungsleitung-Identifikationsystem nach einem der Ansprüche 1 bis 3, dadurch gekennzeichnet, dass das Vermittlungssystem (1) angeordnet ist, einen Rückschleifpfad zu bilden, welcher die ersten und zweiten Kanalverarbeitungssteile (20) nur verbindet, wenn das aus dem ersten Kanal empfangene Signal weitergegeben werden soll.

5. Verbindungsleitung-Identifikationssystem nach einem der Ansprüche 1 bis 4, dadurch gekennzeichnet, dass weiterhin eine Leitungsvermittlung-Steuer einrichtung (30) vorgesehen ist, gekoppelt mit jedem der Kanalverarbeitungssteile (20), zur Steuerung einer Verbindung des Leitungsvermittlungsteils (10) mit dem zweiten Kanal.

6. Verbindungsleitung-Identifikationssystem nach einem der Ansprüche 1 bis 4, dadurch gekennzeichnet, dass jedes Kanalverarbeitungssteil (20) eine Signalverarbeitungseinrichtung (26) enthält, um ein Signal, welches von dem zugehörigen Kanal über das Leitungsvermittlungsteil (10) empfangen bzw. dahin übertragen wird, einer vorbestimmten Signalverarbeitung zu unterwerfen.

7. Verbindungsleitung-Identifikationssystem nach Anspruch 6, dadurch gekennzeichnet, dass weiterhin eine Signalverarbeitungs-Steuer einrichtung (40) vorgesehen ist, gekoppelt mit jedem der Kanalverarbeitungssteile (20), zur Steuerung der Si-
gnalverarbeitungseinrichtung (26) jedes der Kanal-
verarbeitungssteile (20) auf der Grundlage von Aus-
gabesignalen jedes Kanalverarbeitungssteils, wobei
die Signalverarbeitungs-Steuerungseinrichtung (40) die
vorbestimmte Signalverarbeitung in den ersten und
zweiten Kanalverarbeitungssteilen umgeht, wenn
das erste Kanalverarbeitungssteil das Identifikati-
onssignal aus der ersten Einrichtung (23) des zwei-
ten Kanalverarbeitungssteils erfasst.

8. Verbindungsleitungs-Identifikationssystem nach ei-
inem der vorangegangenen Ansprüche, dessen erst-
e und zweite Kanäle jeweils über Verbindungslei-
tungen mit ersten und zweiten Stationen (A, C) wie
zuvor erwähnt verbunden sind.

Revalidations

1. Système d'identification de ligne principale destiné
à former une connexion principale entre (i) une pre-
mière ligne de transmission à une première station
d'un abonné local et (ii) une seconde ligne de trans-
mission à une seconde station, le système compren-
ant une partie (10) de commutation de ligne con-
nectée à chacun de plusieurs canaux dont un pre-
mi est destiné à assurer la connexion à la premiè-
re ligne de transmission et un second est destiné à
assurer la connexion à la seconde ligne de trans-
mission, des parties (20) de traitement de canal as-
sociées respectivement aux canaux, les parties
(20) de traitement de canal étant couplées à la par-
tie (10) de commutation de ligne pour le traitement
de signaux reçus de la première et de la seconde
ligne de transmission et transmis à ces lignes par
l'intermédiaire de la partie (10) de commutation de
ligne, et comprenant chacune un premier et un se-
cond dispositif (23, 24), la partie (10) de commuta-
tion de ligne étant destinée à connecter chaque ca-
nal aux parties correspondantes de traitement de
canal, et un système de commutation (1) connecté
aux parties (20) de traitement de canal et destiné à
fonctionner sélectivement pour relayer un signal re-
çu d'une première partie de traitement de canal (20)
provenant du premier canal par l'intermédiaire de
la partie (10) de commutation de ligne à la seconde
ligne de canal par l'intermédiaire du système de
commutation (1) et une seconde partie (20) de tra-
tement de canal, ou pour transmettre le signal reçu,
par l'intermédiaire du système de commutation, à
un abonné connecté aux systèmes de commutation
(1), et le premier dispositif (23) de la seconde partie
de traitement de canal (20) est destiné à transmet-
tre un signal d'identification à la première partie de
traitement de canal (20) par l'intermédiaire du sys-
tème de commutation (1) lorsque le signal reçu par
la première partie de traitement de canal (20) doit
être relayé, et le second dispositif (24) de la premiè-re partie de traitement de canal (20) est destiné à
déterminer si une ligne est utilisée comme ligne
principale ou non d'après le fait que le signal d'iden-
tification est détecté ou non, la partie (10) de com-
mutation de ligne étant destinée à former la con-
nexion principale entre le premier et le second canal
par l'intermédiaire des premières et secondes par-
ties de traitement de canal lorsque le signal d'iden-
tification est détecté, et à connecter le signal reçu
à un abonné lorsqu'aucun signal d'identification
n'est détecté.

2. Système d'identification de ligne principale selon la
revalidation 1, caractérisé en ce que le premier
dispositif (23) de la seconde partie de traitement de
canal (20) est destiné à créer le signal d'identifica-
tion qui indique le second canal.

3. Système d'identification de ligne principale selon la
revalidation 1 ou 2, caractérisé en ce que les pre-
miers dispositifs (23) des parties (20) de traitement
de canal sont destinés à transmettre le signal d'identification au système de commutation (1) en
sens opposé au sens de connexion d'un appel.

4. Système d'identification de ligne principale selon
l'une quelconque des revalidations 1 à 3, carac-
térisé en ce que le système de commutation (1) est
destiné à former un trajet de boucle de retour qui
connecte les première et seconde parties (20) de
traitement de canal uniquement lorsque le signal re-
çu du premier canal doit être relayé.

5. Système d'identification de ligne principale selon
l'une quelconque des revalidations 1 à 4, carac-
térisé en ce qu'il comporte en outre un dispositif (30)
de commande de commutation de ligne couplé à
chacune des parties (20) de traitement de canal et
destiné à commander la connexion de la partie (10)
de commutation de ligne ou au second canal.

6. Système d'identification de ligne principale selon
l'une quelconque des revalidations 1 à 4, carac-
térisé en ce que chaque partie (20) de traitement
de canal comporte un dispositif (26) de traitement
de signaux destiné à soumettre un signal reçu du
canal associé et transmis à celui-ci par l'intermé-
diaire de la partie (10) de commutation de ligne à
un traitement prédéterminé de signaux.

7. Système d'identification de ligne principale selon la
revalidation 6, caractérisé en ce qu'il comporte en
outre un dispositif (40) de commande de traitement
de signaux couplé à chacune des parties (20) de
traitement de canal et destiné à commander le dis-
positif (26) de traitement de signaux de chacune
des parties (20) de traitement de canal d'après les
signaux de sortie de chacune des parties de traite-
ment de canal, le dispositif (40) de commande de traitement de signaux mettant en dérivation le traitement prédéterminé des signaux dans la première et la seconde partie de traitement de canal lorsque la première partie de traitement de canal détecte le signal d'identification provenant du premier dispositif (23) de la seconde partie de traitement de canal.

8. Système d'identification de ligne principale selon l'une quelconque de revendications précédentes, possédant son premier et son second canal qui sont connectés respectivement par des lignes de transmission à la première et à la seconde station précitéée (A, C).
