Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention.)
Description

Field of the Invention

The present invention relates to a membrane switch according to the preamble of claim 1, used in various electronic devices, incorporating a light illumination of a key top portion by a light emission diode (LED).

Description of the Background Art

As a switch unit to be used in various electronic devices, there has been a light illumination membrane switch which incorporates a light illumination of key top portions by LED for the purpose of easier recognition of the key top portions even in a dark environment.

An exemplary configuration of such a conventional light illumination membrane switch is shown in Fig. 1A, which comprises: a surface sheet 2 with key top portions 1 for forming numerical keys thereon; a translucent diffuser member 3 attached below the surface sheet 2; and a printed circuit board 6 having clicking diaphragm spring members 4 located below the key top portions 1, LED chips 5 located in the diaphragm spring members 4, and connection terminal 6' for connecting to the circuit board members (not shown in Fig. 1A) provided below the clicking diaphragm spring members 4 to an external circuits. These surface sheet 2, the translucent diffuser member 3 and the printed circuit board 6 are assembled together to form a thin layered structure as shown in Fig. 1B.

Here, the translucent diffuser member 3 is made of a silicone rubber, and as shown in Fig. 2, this translucent diffuser member 3 has a plurality of concaved portions 4a for housing the clicking diaphragm spring members 4 and a plurality of concaved portions 5a for housing the LED chips 5, on its back side facing toward the printed circuit board 6 in correspondence to the clicking diaphragm spring members 4 and the LED chips 5 provided on a front surface of the printed circuit board 6.

A key section and a light source section of this conventional light illumination membrane switch have a detailed configuration as shown in Fig. 3, in which the printed circuit board 6 comprises an insulative base layer 6a, electrode circuit members 6b, an adhesive layer 6c, and a cover lay polyimide film 6d, all of which are layered together, and the cover lay polyimide film 6d of this printed circuit board 6 is attached to the translucent diffuser member 3 by an adhesive layer 7.

The clicking diaphragm spring members 4 make electrical contacts with the electrode circuit members 6b in response to the depression of the key top portions 1, as the clicking diaphragm spring members 4 located below the key top portions 1 are convexed downwards in response to the depression of the key top portions 1, and the electrical contacts between the clicking diaphragm spring members 4 and the electrode circuit members 6b can be broken when the depression of the key top portions 1 is released as the clicking diaphragm spring members 4 resume the original upwardly convexed forms, so as to realize an ON/OFF switching function.

The LED chips 5 are commercially available pre-manufactured chip components, and each of the LED chips 5 has a detailed configuration as shown in Fig. 4, which comprises a substrate 9 made of ceramic such as alumina or resin such as glass epoxy, a LED bare chip element 10 mounted on an upper surface of the substrate 9, an electrode member 11 formed over the substrate 9, a bonding wire loop 12 for electrically connecting a terminal at a top of the LED bare chip element 10 and the electrode member 11, and a translucent diffuser resin 13 covering over the LED bare chip element 10 and bonding wire loop 12 completely, where this LED chip 5 is mounted on the printed circuit board 6 through conductive soldering 14 such that the electrode circuit member 11 is electrically connected with the electrode circuit members 6b through this conductive soldering 14.

The total height of the LED chip 5 is normally about 1.2 mm, and when this LED chip 5 is soldered on the printed circuit board 6, the LED chip 5 is elevated above the electrode circuit members 6b by the conductive soldering 14 for about 0.1 mm. Furthermore, for the sake of the sufficient light illumination from the LED chip 5, it is necessary for the translucent diffuser resin 13 to have a thickness of about 0.3 mm above the LED bare chip element 10.

US 4,460,810 discloses a keyboard switch assembly which comprises a flexible film having circuit conductors extending to switch sites. For switching, the switch sites of the flexible film can be pressed against a conductive bottom surface of a recess formed in a support member so as to form a contact between each of said electrodes and the conductive bottom surface of the recess. Passageways extend between adjacent recesses to permit the flow of air between the adjacent switch sites when the flexible film is pressed at a particular switch site.

AT-A-374 961 discloses a switch assembly comprising a number of stacked flexible layers. Between two switching layers having conductors and contact electrodes on opposing surfaces, a spacer layer is disposed and recesses are formed in the spacer layer so as to permit contact electrodes on the opposing surfaces to come in contact with each other through the recesses. Channels connecting the recesses are provided to enable an air flow between the recesses so as to reduce a back pressure when the stacked flexible layers are pushed for switching.

It is the object to provide a new light illumination membrane switch according to the preamble of claim 1 which is improved over the prior art.

This object is achieved by the features as set forth in claim 1.

According to these features, the present invention
provides a light illumination membrane switch capable of realizing an effective light illumination of the key top portions by the LED.

According to another aspect of the present invention there is provided a light illumination membrane switch, comprising: a printed circuit board having electrode circuit member; a key section having a key top portion, the key section being provided over the electrode circuit member to form a switch unit by making an electrical contact with the electrode circuit member in response to a depression of the key top portion; a light source section provided on the printed circuit board in a vicinity of the key section, including an LED bare chip element for emitting lights to illuminate the key section, and a translucent diffuser resin means covering over the LED bare chip element for diffusing and transmitting the lights emitted from the LED bare chip elements; and translucent diffuser means provided around the key section and the light source section for diffusing and transmitting the lights emitted from the light source section, the translucent diffuser means having a cavity region for directly transmitting the lights emitted from the light source section to the key section.

Other features and advantages of the present invention will become apparent from the following description taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring now to Fig. 5 to Fig. 7, a first embodiment of a light illumination membrane switch according to the present invention will be described in detail.

In this first embodiment, a key section (not shown) of the light illumination membrane switch is essentially similar to that of a conventional light illumination membrane switch, but a light source section of the light illumination membrane switch is formed in a configuration as shown in Fig. 5.

Namely, in this first embodiment, there is provided a flexible printed circuit board 20 comprising: an insulative base layer 21 made of a polyimide film having a thickness equal to 25 μm; an electrode circuit member 22 made of copper foil having a thickness equal to 18 μm; and a cover lay film layer 25 provided around the light source section 100, which includes a cover lay adhesive layer 23 having a thickness equal to 25 μm and a cover lay polyimide film 24 having a thickness equal to 25 μm, all of which are layered together.

The light source section 100 is formed above the electrode circuit member 22 of the flexible printed circuit board 20, and comprises: a monocrystal semiconductor LED bare chip element 26 having a width and a depth equal to 0.25 mm and a height equal to 0.30 mm, which is directly mounted on the electrode circuit member 22 by means of a conductive adhesive such as silver paste; a bonding wire loop 27 for electrically connecting a terminal at a top of the LED bare chip element 26 with the electrode circuit member 22; a translucent diffuser resin 28 made of transparent or opalescent epoxy resin, which is covering over the LED bare chip element 26 and the bonding wire loop 27 completely; and a dam member 29 made of silicone resin or plastic resin, which is formed around the translucent diffuser resin 28 to de-
fine an edge of the translucent diffuser resin 28.

An exemplary top plane view of such a light source section 100 according to this first embodiment for a case of incorporating two LED bare chip elements 26 is shown in Fig. B.

Also, as shown in Fig. 7, in the entire light illumination membrane switch configuration, a plurality of such light source sections 100 are provided on the flexible printed circuit board 20 having a connection terminal 20', and arranged between clicking diaphragm spring members 30 also arranged on the flexible printed circuit board 20.

Here, the LED bare chip element 26 having a height equal to 0.3 mm is directly mounted on the electrode circuit member 22 of the flexible printed circuit board 20, so that the top height of the translucent diffuser resin 28 can be set to be about 0.7 mm, and consequently the total thickness of the light source section 100 can be reduced to approximately a half of the thickness of the light source section in a conventional light illumination membrane switch such as that shown in Fig. 3 described above.

Also, an upper surface of the translucent diffuser resin 28 can be shaped into a desired shape by appropriately adjusting a shape of the dam member 29.

Moreover, in this first embodiment, the entire light source section 100 including the LED bare chip element 26 as well as the translucent diffuser resin 28 functions as a light source for providing the light illumination in the light illumination membrane switch, so that the effective light illumination can be realized.

In addition, by limiting the size of the edge of the translucent diffuser resin 28 by means of the dam member 29, the size of the light source section 100 can be made smaller, and consequently, the size of the entire light illumination membrane switch can be reduced.

Furthermore, as each individual LED bare chip element 26 has a very compact size, it becomes possible to arrange more than one LED bare chip elements 26 for emitting lights in different colors within a single light source section 100, such that the light illumination with variously colored lights can be realized in a compact configuration of the light illumination membrane switch.

Referring now to Fig. 8 and Fig. 9, a second embodiment of a light illumination membrane switch according to the present invention will be described in detail. Here, those elements which are substantially equivalent to the corresponding elements in the first embodiment described above will be given the same reference numerals in the drawings and their description will be omitted.

In this second embodiment, a key section and a light source section of the light illumination membrane switch comprise: a surface sheet 32 with key top portions 31 for forming desired alphanumeric keys thereon; a translucent diffuser member 33 attached below the surface sheet 32; the flexible printed circuit board 20 similar to that used in the first embodiment described above, which is attached below the translucent diffuser member 33 by means of an adhesive layer 34; clicking diaphragm spring members 4 located on the flexible printed circuit board 20 below the key top portions 1; and the light source section 100 similar to that of the first embodiment described above.

Here, the surface sheet 32 and the translucent diffuser member 33 may be formed integrally if desired. Also, the surface sheet 32 may be provided as a part of a casing of an electronic device to which this light illumination membrane switch is to be incorporated.

As shown in Fig. 8, the translucent diffuser member 33 has a plurality of concaved portions 36 for housing the clicking diaphragm spring members 30, a plurality of concaved portions 35 for housing the light source section 100, and grooves 37 connecting the neighboring ones of the concaved portions 36 and the concaved portions 35, on its back side facing toward the flexible printed circuit board 20 in correspondence to the clicking diaphragm spring members 30 and the light source sections 100 provided on a front surface of the flexible printed circuit board 20.

The clicking diaphragm spring members 30 make electrical contacts with the electrode circuit members 22 in response to the depression of the key top portions 31, as the clicking diaphragm spring members 30 located below the key top portions 31 are convexed downwards in response to the depression of the key top portions 31, and the electrical contacts between the clicking diaphragm spring members 30 and the electrode circuit members 22 can be broken when the depression of the key top portions 31 is released as the clicking diaphragm spring members 30 resume the original upwardly convexed forms, so as to realize an ON/OFF switching function.

The entire light illumination membrane switch is assembled by properly aligning the surface sheet 32 attached to the translucent diffuser member 33 with the flexible printed circuit board 20 having the clicking diaphragm spring members 30 and the light source sections 100 provided thereon, and attaching them together by means of the adhesive layer 34.

Now, in this second embodiment, the grooves 37 provided in the translucent diffuser member 33 effectively function as cavities to transmit the light emitted from each of the light source sections 100 to the neighboring key sections directly without significant dissipation, so that it becomes possible to realize the effective light illumination in this light illumination membrane switch.

As a consequence, the intensity of the light to be emitted from the LED bare chip element 26 of each light source section 100 required in illuminating the key top portions 31 at a prescribed luminance can be smaller than that required in a conventional light illumination membrane switch, so that the light illumination membrane switch itself can be made to be less power consuming.
In addition, the grooves 37 provided in the translucent diffuser member 33 also function as escape rooms for the air inside the key sections when the key top portions 31 are depressed, so that the improved key touch can be realized at the key top portions 31 as the extra resistance against the depression of the key top portions 31 due to the air pressure of the air inside the key sections can be reduced in this light illumination membrane switch.

It should be apparent that the same advantages as in the first embodiment described above can also be achieved as the light source sections 100 similar to that in the first embodiment are used in this second embodiment.

Referring now to Fig. 10, a third embodiment of a light illumination membrane switch according to the present invention will be described in detail. Here, those elements which are substantially equivalent to the corresponding elements in the first and second embodiments described above will be given the same reference numerals in the drawings and their description will be omitted.

This third embodiment is a modification of the second embodiment described above, and as shown in Fig. 10, in this third embodiment, the translucent diffuser member 33B is formed in a substantially plate-like shape and made of silicone rubber sheet, and between this translucent diffuser member 33B and the flexible printed circuit board 20, there is provided additional translucent diffuser member 38 made of polycarbonate which is attached between the translucent diffuser member 33B and the flexible printed circuit board 20 by means of adhesive layers 34, where this additional translucent diffuser member 38 has grooves 39 connecting the neighboring ones of the key sections and the light source sections, just as the grooves 37 provided in the translucent diffuser member 33B in the second embodiment described above. The remaining features of this third embodiment are substantially similar to those of the second embodiment described above.

Here, the light illumination in this third embodiment can be further improved by using the additional translucent diffuser member 38 which is substantially transparent and providing a surface coating in white or silver on an upper surface of the additional translucent diffuser member 38 as well as on the upper surface of the cover lay polyimide film 24, so as to improve the light transmission from the light source section to the key section.

It should be apparent that the same advantages as in the first and second embodiments described above can also be achieved in this third embodiment.

Referring now to Fig. 11 and Fig. 12, a fourth embodiment of a light illumination membrane switch according to the present invention will be described in detail. Here, those elements which are substantially equivalent to the corresponding elements in the first and second embodiments described above will be given the same reference numerals in the drawings and their description will be omitted.

This fourth embodiment is another modification of the second embodiment described above, and as shown in Fig. 11 and Fig. 12, in this fourth embodiment, the light illumination membrane switch is installed in an electronic device body 40, and the translucent diffuser member 33C is formed to have a side wall portion 41 and an indented portion 42 surrounded by the side wall portion 41, where the inner size of an opening defined by the side wall portion 41 corresponding to the outer size of the flexible printed circuit board 20, such that the flexible printed circuit board 20 can be inserted into the opening defined by the side wall portion 41 of the translucent diffuser member 33 and adhered to the indented portion 42 by means of the adhesive layer 34. The remaining features of this third embodiment are substantially similar to those of the second embodiment described above.

Here, because of this side wall portion 41 of the translucent diffuser member 33, the alignment of the flexible printed circuit board 20 with respect to the translucent diffuser member 33 can be made easily by simply fitting the flexible printed circuit board 20 into the opening defined by the side wall portion 41 of the translucent diffuser member 33.

On the other hand, as the flexible printed circuit board 20 is tightly fitted into the opening defined by the side wall portion 41 of the translucent diffuser member 33, the possible curving of the translucent diffuser member 33 itself can be adjusted.

Moreover, the flexible printed circuit board 20 is tightly fitted into the opening defined by the side wall portion 41 of the translucent diffuser member 33 while the translucent diffuser member 33 itself has a significant water repellency, and in addition the possible route for invasion of the moisture and dust through the border of the flexible printed circuit board 20 and the translucent diffuser member 33 indicated by an arrow 45 in Fig. 11 is complicated, so that invasion of the moisture and dust through the border of the flexible printed circuit board 20 and the translucent diffuser member 33 due to the capillary phenomenon can be effectively prevented.

For this reason, this light illumination membrane switch of the fourth embodiment is capable of realizing a highly reliable operation and improved durability even under the high humidity environment or in a case of water leakage.

It should be apparent that the same advantages as in the first and second embodiments described above can also be achieved in this fourth embodiment.

Referring now to Fig. 13 and Fig. 14, a fifth embodiment of a light illumination membrane switch according to the present invention will be described in detail. Here, those elements which are substantially equivalent to the corresponding elements in the first and second embodiments described above will be given the same reference numerals in the drawings and their description will be omitted.
In this fifth embodiment, as shown in Fig. 13, the light illumination membrane switch comprises: an outer casing 50 having openings 51 corresponding to keys, a sheet shaped keypad 52 made of translucent rubber material such as silicone rubber, which is located between the outer casing 50 and the insulative base layer 21 and which has key portions 53 projecting out from a sheet shaped body of the keypad 52 into the openings 51 of the outer casing 50 and a light source section housing 58 for housing the light source section 100: upper and lower reflective coating layers 54 and 55 formed on upper and lower sides of the keypad 52 by using a paint medium in white or silver having a significant reflectivity: a colored paint layer 56 formed on top surfaces of the key portions 53; and a black paint layer 57 formed over the upper reflective coating layer 54 and the colored paint layer 56, where the black paint layer 57 over the colored paint layer 56 is partially removed by laser etching process to expose the colored paint layer 56 in shapes of the desired alphanumeric figures.

The key sections also includes the electrode circuit members 22 and the clicking diaphragm spring members 30 similar to those of the second embodiment described above, which are formed below the key portions 53 of the keypad 52, while the light source sections 100 similar to those of the first and second embodiments described above are formed inside the light source section housing 58 provided inside the sheet shaped body of the keypad 52.

Here, the light emitting portion of the LED bare chip element in the light source section 100 is located below the upper reflective coating layer 54 and above the lower reflective coating layer 55, such that the lights emitted from the light source section 100 are transmitted through the keypad 52 while being repeatedly reflected between the upper and lower reflective coating layers 54 and 55, until they reach to the key portions 53 to illuminate the colored paint layer 56.

In this fifth embodiment, the keypad 52 fulfills the functions of both the surface sheet and the translucent diffuser member in the second embodiment described above, so that the height H between the outer casing 50 and the insulative base layer 21 can be further reduced compared with the second embodiment described above. Consequently, a further reduction of an overall thickness of the entire light illumination membrane switch can be realized. In fact, by means of this configuration, it becomes possible for this light illumination membrane switch of the fifth embodiment to realize the overall thickness in a range of 0.5 mm to 1.5 mm.

Moreover, by forming the reflective coating layers 54 and 55 from the paint medium in white, it is possible to subdue the color difference between the lights emitted by the LED bare chip element in the light source section 100 and the colored paint layer 56.

It is to be noted that the similar advantageous effect can also be obtained to lesser extent by omitting the lower reflective coating layer 55 and limiting the upper reflective coating layer 54 to regions between the neighboring key sections, as shown in Fig. 14.

As described above, according to the present invention it becomes possible to provide a light illumination membrane switch with a thickness much smaller than a conventional light illumination membrane switch. Moreover, according to the present invention, such a thin light illumination membrane switch can be made to be able to realize an effective light illumination of the keys, and a highly reliable operation even under the high humidity environment.

It is to be noted that besides those already mentioned above, many modifications and variations of the above embodiments may be made without departing from the novel and advantageous features of the present invention. Accordingly, all such modifications and variations are intended to be included within the scope of the appended claims.

Claims

1. A light illumination membrane switch, comprising:

   a printed circuit board (20) having electrode circuit member (22);
   a key section (30, 31, 53) having a key top portion (31, 56), the key section (30, 31, 53) being provided over the electrode circuit member (22) to form a switch unit by making an electrical contact with the electrode circuit member (22) in response to a depression of the key top portion (31, 53);
   a light source section (100) provided on the printed circuit board (20) in a vicinity of the key section (30, 31, 53), including an LED bare chip element (26) for emitting lights to illuminate the key section (30, 31, 53), and a translucent diffuser resin means (28) covering over the LED bare chip element (26) for diffusing and transmitting the lights emitted from the LED bare chip elements (26); and
   translucent diffuser means (33, 33C, 52) provided around the key section (30, 31) and the light source section (100) for diffusing and transmitting the lights emitted from the light source section (100);

   characterized in that
   the translucent diffuser means (33, 33C, 52) has a cavity region (37) for directly transmitting the lights emitted from the light source section (100) to the key section (30, 31).

2. The light illumination membrane switch of claim 1, wherein the translucent diffuser means (33) includes a first translucent diffuser member (33B) provided over the key section (30, 31) and the light
source section (100), and a second translucent diffuser member (38) having the cavity region (39) which is attached below the first translucent diffuser member (33B).

3. The light illumination membrane switch of claim 1, wherein the translucent diffuser means (33) is made of silicone rubber.

4. The light illumination membrane switch of claim 1, wherein the LED bare chip element (26) is directly mounted on the electrode circuit member (22) of the printed circuit board (20).

5. The light illumination membrane switch of claim 4, wherein the printed circuit board (20) is a flexible printed circuit board.

6. The light illumination membrane switch of claim 4, wherein the LED bare chip element (26) has a terminal which is wire bonded to the electrode circuit member (22).

7. The light illumination membrane switch of claim 4, further comprising a dam member (29) provided around the translucent diffuser resin means (28) for defining an edge of the translucent diffuser resin means (28).

8. The light illumination membrane switch of claim 4, wherein the light illumination membrane switch as a whole has an overall thickness in a range of 0.5 mm to 1.5 mm.

9. The light illumination membrane switch of claim 1, wherein the translucent diffuser means (33C) has a side wall portion (41) defining an opening such that the translucent diffuser means (33C) and the printed circuit board (20) are assembled together by inserting the printed circuit board (20) into the opening defined by the side wall portion (41).

10. The light illumination membrane switch of claim 9, wherein the translucent diffuser means (33C) also has an indented portion (42) surrounded by the side wall portion (41), where the printed circuit board (20) is adhered to the indented portion (20) when the translucent diffuser means (33C) and the printed circuit board (20) are assembled together.

11. The light illumination membrane switch of claim 9, wherein the translucent diffuser means (33C) is made of silicone rubber.

12. The light illumination membrane switch of claim 1, wherein the translucent diffuser means (52) has reflective coating means (54, 55) formed thereon for reflecting the lights emitted from the light source section (100) into the translucent diffuser means (52).

13. The light illumination membrane switch of claim 12, wherein the key section (53) and the translucent diffuser means (52) are formed integrally in a form of a keypad (52, 53) comprising a key portion (53) functioning as the key section (53), and a sheet body portion (52) functioning as the translucent diffuser means (52), the sheet body portion (52) including a housing (58) for the light source section (100) such that the light source section emits the lights inside the sheet body portion (52) of the keypad (52, 53).

14. The light illumination membrane switch of claim 12, wherein the reflective coating means (54, 55) includes an upper reflective coating (54) and a lower reflective coating (55) provided on an upper surface and a lower surface of the translucent diffuser means (52), respectively.

15. The light illumination membrane switch of claim 12, wherein the reflective coating means (54, 55) is formed by painting a paint medium in a color of any one of white and silver.

16. The light illumination membrane switch of claim 12, wherein the translucent diffuser means (52) is made of silicone rubber.

Patentansprüche

1. Ein beleuchteter Membranschalter mit:

einer gedruckten Schaltungsplatine (20) mit einem Elektrodenschaltungselement (22);

einem Betätigungsschnitt (30, 31, 53) mit einem oberen Betätigungsteil (30, 31, 53), wobei der Betätigungsschnitt (30, 31, 53) über dem Elektrodenschaltungselement (22) vorgesehen ist zur Bildung einer Schaltbereinheit unter Herstellung eines elektrischen Kontakts mit dem Elektrodenschaltungskreiselement (22) in Er- widerung auf eine Druckauslösung auf den oberen Betätigungsteil (31, 53);

einem Lichtquellenabschnitt (100), der auf der gedruckten Schaltkreisschaltung (20) in der Nähe des Betätigungsschnitts (30, 31, 53) vorgesehen ist, mit einem blanken LED-Chiplement (26) zur Emission von Licht zur Beleuchtung des Betätigungsschnitts (30, 31, 53) und einem durchscheinenden Diffusorharzmittel (28), das das blanken LED-Chiplement (26) abdeckt, zum Diffusmachen und Transmitten...
von dem blanken LED-Chipelement (26) emittiertem Licht; und

einem durchscheinenden Diffusormittel (33), (33C, 52), das um den Betätigungseabschnitt (30, 31) und den Lichtquellenabschnitt (100) herum vorgesehen ist zum Diffusmachen und Transmittieren von dem Lichtquellenab- schnitt (100) emittiertem Licht. dadurch gekennzeichnet, daß das durchscheinende Diffusormittel (33, 33C, 52) einen Aushöhlungsbereich (37) aufweist zum direkten Transmittieren des von dem Lichtquellenabschnitt (100) emittierten Lichts zu dem Betätigungseabschnitt (30, 31).

2. Der beleuchtete Membranschalter nach Anspruch 1, wobei das durchscheinende Diffusormittel (33) ein erstes durchscheinendes Diffusorelement (33B), das über dem Betätigungseabschnitt (30, 31) und dem Lichtquellenabschnitt (100) vorgesehen ist, und ein zweites durchscheinendes Diffusorelement (38) enthält, das den Aushöhlungsbereich (39) aufweist, und das unterhalb des ersten durch- scheinenden Diffusorelements (33B) angebracht ist.

3. Der beleuchtete Membranschalter nach Anspruch 1, wobei das durchscheinende Diffusormittel (33) aus Silikongummi hergestellt ist.

4. Der beleuchtete Membranschalter nach Anspruch 1, wobei das blanke LED-Chipelement (26) direkt auf dem Elektrodenschaltungselement (22) der gedruckten Leiterplatte (20) angebracht ist.

5. Der beleuchtete Membranschalter nach Anspruch 4, wobei die gedruckte Leiterplatte (20) eine flexible gedruckte Leiterplatte ist.

6. Der beleuchtete Membranschalter nach Anspruch 4, wobei das blanke LED-Chipelement (26) einen Anschluß aufweist, der eine Drahtbindung zu dem Elektrodenschaltungselement (22) aufweist.

7. Der beleuchtete Membranschalter nach Anspruch 4, weiter mit einem Dammelement (29), das um das durchscheinende Diffusorharzmittel (28) vorgese- hen ist, zum Bestimmen einer Kante des durch- scheinenden Diffusorharzmittels (28).

8. Der beleuchtete Membranschalter nach Anspruch 4, wobei der beleuchtete Membranschalter als Gan- zes eine insgesamte Dicke in einem Bereich von 0,5 mm bis 1,5 mm aufweist.

9. Der beleuchtete Membranschalter nach Anspruch 1, wobei das durchscheinende Diffusormittel (33C) einen Seitenwandbereich (41) aufweist, der eine Öffnung derart bestimmt, daß das durchscheinende Diffusormittel (33C) und die gedruckte Leiterplatte (20) durch Einfügen der gedruckten Leiterplatte (20) in die in dem Seitenwandbereich (41) be- stimmte Öffnung zusammengefügt werden.

10. Der beleuchtete Membranschalter nach Anspruch 9, wobei das durchscheinende Diffusormittel (33C) auch einen Einrückbereich (42) aufweist, der durch den Seitenwandbereich (41) umgeben wird, wo die gedruckte Leiterplatte (20) an dem Einrückbereich (20) anhaftet, wenn das durchscheinende Diffusor- mittel (33C) und die gedruckte Leiterplatte (20) zu- sammengefügt werden.

11. Der beleuchtete Membranschalter nach Anspruch 9, wobei das durchscheinende Diffusormittel(33C) aus Silikongummi hergestellt ist.

12. Der beleuchtete Membranschalter nach Anspruch 1, wobei das durchscheinende Diffusormittel (52) reflektierende Beschildungsmittel (54, 55), die daraus ausgebildet sind, aufweist zum Reflektieren das von dem Lichtquellenabschnitt (100) emittier- ten Lichts in das durchscheinende Diffusormittel (52).

13. Der beleuchtete Membranschalter nach Anspruch 12, wobei der Betätigungseabschnitt (53) und das durchscheinende Diffusormittel (52) integral in der Form eines Betätigungselemente (52, 53) mit einem Betätigungsteil (53), der als der Betätigungseabschnitt (53) wirkt, und einem Schichtkörperteil (52), der als das durchscheinende Diffusormittel (52) wirkt, ausgebildet sind, wobei der Schichtkörperteil (52) ein Gehäuse (58) für den Lichtquellenabschnitt (100) enthält, so daß der Lichtquellenabschnitt das Licht innerhalb des Schichtkörperteils (52) des Betä- tigungselemente (52, 53) emittiert.

14. Der beleuchtete Membranschalter nach Anspruch 12, wobei das reflektierende Beschildungsmittel (54, 55) eine obere reflektierende Beschildung (54) und eine untere reflektierende Beschildung (55) enthält, die jeweils auf einer oberen Oberfläche und einer unteren Oberfläche des durchscheinen- des Diffusormittels (52) vorgesehen sind.

15. Der beleuchtete Membranschalter nach Anspruch 12, wobei das reflektierende Beschildungsmittel (54, 55) durch Aufziehen eines Anstrichmediums in einer weißen oder silbernen Farbe hergestellt wird.

16. Der beleuchtete Membranschalter nach Anspruch 12, wobei das durchscheinende Diffusormittel (52)
aus Silikongummi hergestellt ist.

**Revendications**

1. Interrupteur à membrane à éclairage comprenant :
   une carte (20) à circuit imprimé possédant un élément (22) de circuit d'électrode ;
   une section de touche (30, 31, 53) comportant une partie supérieure de touche (31, 56), la
   section de touche (30, 31, 53) étant prévue sur l'élément (22) de circuit d'électrode pour former
   un module d'interrupteur en créant un contact électrique avec l'élément (22) de circuit d'électrode
   en réponse à une pression exercée sur la partie supérieure de touche (31, 53) :
   une section (100) de source de lumière prévue sur la carte (20) à circuit imprimé au voisinage
   de la section de touche (30, 31, 53), incluant un élément LED (diode émettrice de lumière) (26)
   à puce nue destiné à émettre de la lumière pour éclairer la section de touche (30, 31, 53) ; et un
   moyen diffuseur (28) en résine translucide recouvrant l'élément LED (26) à puce nue pour
   diffuser et transmettre la lumière émise par les éléments LED (26) à puce nue ; et
   un moyen diffuseur translucide (33, 33C, 52) placé autour de la section de touche (30, 31) et
   de la section (100) de source de lumière pour diffuser et transmettre la lumière émise par la
   section (100) de source de lumière ;
   caractérisé en ce que :
   le moyen diffuseur translucide (33, 33C, 52) comporte une zone de cavité (37) pour transmettre
directement la lumière émise par la section (100) de source de lumière à la section de touche (30, 31).

2. Interrupteur à membrane à éclairage selon la revendication 1, dans lequel le moyen diffuseur translucide (33) comprend un premier élément diffuseur translucide (33B) disposé sur la section de touche (30, 31) et la section (100) de source de lumière, et un second élément diffuseur translucide (38) comportant une région de cavité (39), qui est fixé sous le premier élément diffuseur translucide (33B).

3. Interrupteur à membrane à éclairage selon la revendication 1, dans lequel le moyen diffuseur translucide (33) est fait de caoutchouc de silicone.

4. Interrupteur à membrane à éclairage selon la revendication 1, dans lequel l'élément LED (26) à puce nue est monté directement sur l'élément (22) de circuit d'électrode de la carte (20) à circuit imprimé.

5. Interrupteur à membrane à éclairage selon la revendication 4, dans lequel la carte (20) à circuit imprimé est une carte à circuit imprimé souple.

6. Interrupteur à membrane à éclairage selon la revendication 4, dans lequel l'élément LED (28) à puce nue comporte une borne qui est reliée par fil à l'élément (22) de circuit d'électrode.

8. Interrupteur à membrane à éclairage selon la revendication 4, dans lequel l'interrupteur à membrane à éclairage globalement a une épaisseur totale dans une fourchette de 0,5 mm à 1,5 mm.

9. Interrupteur à membrane à éclairage selon la revendication 1, dans lequel le moyen diffuseur translucide (33C) comporte une partie paroi latérale (41) définissant une ouverture de façon telle que le moyen diffuseur translucide (33C) et la carte (20) à circuit imprimé sont assemblés l'un à l'autre par l'introduction de la carte (20) à circuit imprimé dans l'ouverture définie par la partie paroi latérale (41).

10. Interrupteur à membrane à éclairage selon la revendication 9, dans lequel le moyen diffuseur translucide (33C) comporte aussi une partie dentelée (42) entourée par la partie paroi latérale (41), carte (20) à circuit imprimé étant collée à la partie dentée (20), lorsque le moyen diffuseur translucide (33C) et la carte (20) à circuit imprimé sont assemblés l'un à l'autre.

11. Interrupteur à membrane à éclairage selon la revendication 9 dans lequel le moyen diffuseur translucide (33C) est fait de caoutchouc de silicone.

12. Interrupteur à membrane à éclairage selon la revendication 1, dans lequel le moyen diffuseur translucide (52) possède un moyen (54, 55) formant rétèvement réfléchissant formé sur lui pour réfléchir la lumière émise par la section (100) de source de lumière dans le moyen diffuseur translucide (52).

13. Interrupteur à membrane à éclairage selon la revendication 12, dans lequel la section de touche (53) et le moyen diffuseur translucide (52) sont formés d'un seul tenant en une forme de clavier (52, 53) comportant une partie touche (53) servant de section de touche (53), et une partie corps de feuille (52) servant de moyen diffuseur translucide (52), la partie corps de feuille (52) incluant un logement (58) pour la section (100) de source de lumière de façon telle que la section de source de lumière émette de
la lumière à l’intérieur de la partie corps de feuille (52) du clavier (52, 53).

14. Interrupteur à membrane à éclairage selon la revendication 12, dans lequel le moyen (54, 55) formant revêtement réfléchissant comprend un revêtement réfléchissant supérieur (54) et un revêtement réfléchissant inférieur (55) disposés, respectivement, sur une surface supérieure et sur une surface inférieure du moyen diffuseur translucide (52).

15.Interrupteur à membrane à éclairage selon la revendication 12, dans lequel le moyen (54, 55) formant revêtement réfléchissant est formé en peignant un support peint d’une couleur soit blanche soit argentée.

16. Interrupteur à membrane à éclairage selon la revendication 12, dans lequel le moyen diffuseur translucide (52) est fait de caoutchouc de silicone.
