Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).
Description

The invention relates to a die for ceramic tiles. For the production of ceramic tiles a process which has been in use for some time is one that substantially consists in the pressing of the powders between two half-dies, with the aim of obtaining the compression of the said powders and the formation of the tile which will be of a shape determined by the form of the empty space created between the two half-dies when the die is completely closed.

Once the operation has been finished, the tile is sent to be fired, which completes the process.

Sometimes, during the firing, some differentiated shrinkage of the tile occurs, leading to a deformation of the tile itself; the tile, according to the entity of the shrinking, is thus considered to be no longer of first quantity but of faulty quality, or even waste.

The differentiated shrinking of the parts of the tile is determined by the different density of the parts which are created during the compressing process.

The causes which determine the different density (or rather the non-homogeneity) of the said parts of the tile are firstly the non-homogeneity of the powders and, principally, the non-uniform distribution of the powders in the die. If, in a zone of the die, there is a larger quantity of powder, or a powder of higher density with respect to the remaining powder, the tile in that zone will be, after the compressing process, denser with respect to the other parts of the tile and will have a smaller shrinkage if the piece is taken to be fired up to gresification, or it will be less porous in the case in which the piece itself, without shrinkage, remains porous after firing.

To obviate this drawback dies with elastic membranes tensed by underlying pressurised fluid have been used, which technique is well established in the prior art and used for other ceramic products such as plates, insulating elements and similar (see e.g. Italian Patent no. 1158781). The above dies have not, however, up to now, given good results in that the piece that comes out of the dies is deformed by convexities and concavities, which can be acceptable for products already shaped but which is not acceptable for tiles which must have flat laying surfaces both for the subsequent firing and for the laying.

An aim of the present invention is thus that of eliminating the above-mentioned drawbacks by providing a die which permits of obtaining a tile having equal overall density, even in the case where there is non-homogeneity in the powders used or non-uniform distribution of the powders themselves in the die and which enables the tile laying surfaces to be kept flat.

An advantage of the present invention is that of providing a die which is constructionally cheap and usable with normal presses of the types already in use.

These aims and advantages and others besides are all attained by the invention, as it is characterised in the claims that follow, which comprises two semi-dies, between which the material is compressed, at least one of which dies exhibits an elastic wall, on which wall external face the imprint of one of the faces to be realised is inscribed, which overlies a cavity filled with an incompressable fluid, divided into portions by a lattice.

Further characteristics and advantages of the present invention will better emerge from the detailed description that follows, of an embodiment of the invention, herein illustrated purely in the form of a non-limiting example in the accompanying figures, in which:

- Figure 1 shows a view from above of one of the semi-dies of the die object of the invention;
- figure 2 shows a section, made according to plane II-II of figure 1, of the semi-die of figure 1, superiorly to which the sections of a tile and of the second semi-die are illustrated.

The die comprises two half-dies 1 and 2 between which the material to be compressed is pressed; the half-die 2 has a flat surface and reproduces the smooth face 6a of the tile 6, while the half-die 1 has a shaped surface that reproduces the inferior part 6b of the tile itself. As in the present applications, the two half-dies 1 and 2 are contained in a lateral frame, not illustrated, and can be reciprocally approached and distanced. The half-die 1, destined to reproduce the inferior surface 6b of the tile 6, comprises a concave, rigid base 3 which defines a cavity 5 superiorly closed by an elastic wall 4 which is solidly anchored to the edges of the rigid base 3 and completely insulates the cavity 5 from the external space.

The elastic wall 4 can be made with natural or synthetic elastomers. On its external surface the imprint of the inferior part of the tile is inscribed.

In the embodiment shown in the figure, the inferior part of the tile is equipped with a continuous lattice, for which reason the imprints on the elastic wall 4 are also continuous: obviously nothing technical changes in cases where the inferior surface of the tile must be inscribed with discrete points.

In the cavity 5 a lattice 7 is arranged, on which the elastic wall 4 rests, which lattice 7 divides the said cavity 5 into a plurality of portions 9.

The elastic wall 4 is solidly anchored to the lattice; the imprint made on the elastic wall 4 is arranged by means of the said lattice.
In the various tracts that form the lattice 7 through-holes 8 are envisaged which place all of the portions 9 in connection among themselves. The cavity 5 is full of an incompressible fluid which can be, for example, water, oil or other liquids.

For the realisation of the tile a prefixed quantity of powder, destined to be pressed in the die, is distributed on the lower half-die 2 which, as has been mentioned in precedence, is laterally defined by a lateral containing frame, in the most uniform way possible. It should be mentioned that the lower die can be equally half-die 1, as in the figures, or half-die 2.

The half-dies 1 and 2 are thus reciprocally closed in such a way as to press the powder and cause its compression.

Contrarily to what happens in the case of dies of known type, in which the pressure exerted in the areas with a greater quantity of powder is greater (and thus the density is higher in the tile in the said areas), the die object of the invention exerts the same pressure on all the parts of the tile. This is due to the presence of fluid in the cavity 5 and to the elastic nature of the elastic wall 4 closing the cavity 5 and acting directly on the powders to be compressed.

In the areas having a larger quantity of powder there will be a slight increase in the thickness of the tile, with the consequent formation of small convexities 10, while in the areas with a smaller quantity of powder there will be a slight diminution of the thickness of the tile with a consequent formation of a small concavity 11. All this does not lead to any drawback, since these small deformations are arranged on the already-shaped inferior surface of the tile and are contained within the space defined by the inferior surface of the tile-lattice itself. The presence of the lattice 7 ensures the always-perfect coplanarity of the inferior lattice, even for tiles of considerable size.

The important fact is that all of the areas of the tile are subjected to the same pressure and thus have the same density.

An exception to this is the surface occupied by the lattice, where the die behaves like a traditional rigid die. This surface represents however a very limited percentage of the total surface of the tile; further, the width of the lattice tracts is very limited, for which reason, in these areas, the overlying powders distribute, in the moment in which they receive the compression, with a motion which is at least partially fluid-type.

In the subsequent firing phase, this characteristic will lead to the avoidance of deformations in the tile if the tile is sent to be fired up until gresification, or, in the case in which it does not reach the gresification stage, the forming of too-differentiated porous areas.

The lattice of the tile is however always flat and permits a perfect resting of the tile both during the firing phase and during the laying phase.

Claims

1. A die for ceramic tiles of the type comprising two half-dies (1) and (2) between which the material to be compacted is pressed, at least one of which two half-dies (1) or (2) is of a special type and comprises a rigid, concave base (3) which defines a cavity (5) which cavity (5) is filled with an incompressible fluid and which cavity (5) is closed by an elastic wall (4) on which elastic wall (4) external face the imprint of one of the faces of a tile to be realised (6) is inscribed characterised in that a lattice (7) is arranged in the cavity (5), which lattice (7) divides the said cavity (5) into a plurality of portions (9) and defines a laying-surface for the said elastic wall (4), to which laying surface the elastic wall (4) is solidly anchored; the said imprint is made at the position of the said lattice (7); permitting to obtain a tile having equal overall density and enabling the tile laying-surfaces to be kept flat.

2. A die as in claim 1, characterised in that a plurality of through-holes (8) are bored into the various tracts which form the said lattice (7), which through-holes (8) are conformed and arranged in such a way as to place all of the said portions (9) in mutual communication.

3. A die as in claim 1, characterised by the fact that only the half-die (1) bearing the imprint for the realisation of the inferior part (6b) of the tile (6) is of a special type.

Patentansprüche

1. Eine Form für Keramikziegel, die typischwerweise aufweist: Zwei Formhälften (1) und (2), zwischen denen das zu kompaktierende Material gepreßt wird, wobei zumindest eine dieser Formhälften (1) oder (2) von besonderer Art ist und eine feste, konkave Basis (3) aufweist, die einen Hohlraum (5) definiert, wobei dieser Hohlraum (5) mit einer nicht komprimierbaren Flüssigkeit gefüllt ist und wobei der Hohlraum (5) durch eine elastische Wand (4) verschlossen wird, wobei auf der Außenseite der elastischen Wand (4) der Abdruck einer Seite der zu fertigenden Fliese (6) eingeschrieben ist, dadurch gekennzeichnet, daß ein Rastergitter (7) in dem Hohlraum (5) angeordnet ist, wobei das Rastergitter (7) den Hohlraum (5) in eine
3. Une matrice comme celle de la revendication 1, caractérisée en ce fait que seulement la demi-matrice (1) qui porte l'empreinte pour la réalisation de la partie inférieure (6b) de la tuile (6) est d'un type spécial.

2. Une matrice comme celle de la revendication 1, caractérisée en ce fait qu'une pluralité de trous passants (8) sont percés dans les différentes parties qui forment le dit treillis (7), ces trous passants (8) sont conformés et disposés de façon à mettre toutes lesdites portions (9) en communication mutuelle.

Reveniations

1. Une matrice pour tuiles céramiques du type qui comprend deux demi-matrices (1) et (2) entre lesquelles le matériau qui doit être compacté est mis sous presse, au moins l'une de ces deux demi-matrices (1) ou (2) est d'un type spécial et comprend une base rigide et concave (3) qui délimite une cavité (5), cette cavité (5) est remplie d'un fluide incompressible et cette cavité (5) est fermée par une paroi élastique (4) sur la face externe de cette paroi élastique (4) est gravée l'empreinte d'une des faces de la tuile qui doit être réalisée (6) caractérisée en ce fait qu'un treillis (7) est disposé dans la cavité (5), ce treillis (7) divise ladite cavité (5) en une pluralité de portions (9) et délimite une surface d'appui pour ladite paroi élastique (4), la paroi élastique (4) est solidairement ancrée à cette surface d'appui ; ladite empreinte est faite dans la position dudit treillis (7) ; permettant d’obtenir une tuile qui ait une densité égale partout et permettant que les surfaces d'appui de la tuile restent plates.

2. Une matrice comme celle de la revendication 1, caractérisée en ce fait qu'une pluralité de trous passants (8) sont percés dans les différentes parties qui forment le dit treillis (7), ces trous passants (8) sont conformés et disposés de façon à mettre toutes lesdites portions (9) en communication mutuelle.
