Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
This invention relates to a process for producing a thermoplastic polyurethane elastomer, and an apparatus for producing same. More specifically, this invention relates to a process for producing a polyurethane elastomer having a high molecular weight and a narrow molecular-weight distribution and containing a very small amount of polyurethane substrate-based small grains, and an apparatus for producing same.

Background technique

As a method for producing thermoplastic polyurethane, a solution polymerization method using a solvent and a bulk melt polymerization method not using a solvent have been known.

A method for producing a polyurethane elastomer by solution-polymerizing a polymer glycol, a diisocyanate compound and a crosslinking agent batchwise in a solvent gives a polyurethane elastomer having a relatively narrow molecular-weight distribution, but does not provide so high a degree of polymerization, requires a step of separating the solvent from the reaction product after the reaction, and is batchwise. Therefore, said method is extremely inefficient.

Japanese Patent Publication Sho 39-17093 (No. 17,093/1964) discloses a method for producing a polyurethane elastomer by bulk-polymerizing a polymer glycol and a diisocyanate compound batchwise in the absence of a solvent with a kneading machine such as a kneader.

This method affords a polyurethane elastomer having a high degree of polymerization. However, this polyurethane elastomer has a wide molecular-weight distribution and shows strong adhesion, so that said elastomer can hardly be peeled off from a rotating blade. In general, when conducting the reaction batchwise, it is very hard to strictly regulate the proportion of starting materials to be fed in each batch, treatment temperatures, treatment times, a water content or extraction times. Due to this, a degree of polymerization and a molecular-weight distribution cannot be controlled and hence, it is quite difficult to make products uniform.

On the other hand, Japanese Patent Publication Sho 44-25600 (No. 25,600/1969) discloses a method for continuously producing a thermoplastic polyurethane resin, which comprises kneading a heat-molten liquid polyisocyanate compound and a compound containing at least two groups having an active hydrogen capable of reacting with an isocyanate group in a multi-screw extruder for a residence time of 3 to 60 minutes to polymerize them. This document describes 50 to 200°C as a polymerization temperature, and employs a residence time of 7 to 15 minutes and a polymerization temperature (a cylinder temperature) of 140 to 195°C in Examples.

Japanese Patent Publication Sho 49-3451 (No. 3,451/1974) discloses a method for producing polyurethane elastic yarns by a continuous synthesis in the absence of a solvent and a direct spinning, which method includes a step of preliminarily reacting a high-molecular dihydroxy compound having a molecular weight of 500 or more with an organic isocyanate such that 70 to 100 % of a finally necessary amount of the high-molecular dihydroxy compound substantially becomes an isocyanate group. Said document shows 150 to 250°C as a reaction temperature of a prepolymer formed in the above preliminary reaction step, the remaining high-molecular dihydroxy compound and a low-molecular dihydroxy compound, and adopts 180°C x 15 minutes and 160°C x 20 minutes as reaction conditions in Examples.

Japanese Patent Publication Hei 3-54963 (No. 54,963/1991) discloses a method in which continuously producing a thermoplastic polyurethane by reacting in an extruder a high-molecular diol having an average molecular weight of 500 to 3,000, a low-molecular diol having a molecular weight of less than 500 and an organic disocyanate, a molar ratio of the amount of isocyanate groups of the organic disocyanate to a total amount of hydroxyl groups of the high-molecular diol and the low-molecular diol is adjusted to the range of 1 ± 0.002 to control variation in melt viscosity of the resulting polyurethane. Said document describes that regarding the reaction (polymerization) temperature in the extruder, when the temperature is too high, the reaction rate becomes high and the mixing rate becomes low relatively, so that the mixing is insufficient and uniform polyurethane cannot be obtained or decomposition of the organic disocyanate and the reaction product occurs, which is therefore undesirable. The recommended polymerization temperature (a temperature inside the extruder) which is adopted in Examples of said document is 220°C at the highest. Said document does not have a description of 220°C or higher.

Japanese Laid-open Patent Application (Kokai) Hei 2-20514 (No. 20,514/1990) discloses a process for producing thermoplastic polyurethane by melt polymerization using, as a high-molecular diol, a polyester diol or a poly-carbonate diol containing a residue of 2-methyl-1,8-octanediol or a residue of 1,9-nonanediol. Said document shows a polymerization temperature of at least 200°C but at most 240°C, and describes that with the polymerization temperature of 240°C or lower, heat resistance of the resulting thermoplastic polyurethane increases.

Japanese Laid-open Patent Application (Kokai) Hei 2-191621 (No. 191,621/1990) discloses a thermoplastic polyurethane in which MB, MB being MFR (a melt flow ratio) at 220°C, is 5 to 50 and a ratio (MB/MA), MA being MFR
at 200°C, of 1 to 5. Said document states that the thermoplastic polyurethane has low temperature dependence of melt fluidity near 200°C and is uniform and that conventional polyurethane containing an undissolved material or gel in large amounts cannot achieve this value. It is described in this document that the undissolved material is judged by dissolving a given amount of polyurethane in dimethylformamide at room temperature and measuring an amount (wt. %) of the undissolved material. Said document discloses Example in which the reaction (polymerization) of a prepolymer from a high-molecular diol and an organic diisocyanate with a low-molecular diol was conducted at a fixed temperature of 200°C and Example in which the reaction was conducted at progressively elevated temperatures of 180 to 200°C.

[0011] The present inventors’ investigations have revealed, however, that the polyurethane elastomer obtained by the above techniques, when subjected to ordinary melt-spinning, has difficulty in controlling the spinning temperature, allows formation of gels that prevent passage through a filter, and causes yarn breakage in spinning, etc. As a result, spinning for a long time is impossible, the yield varies in the range of 50 to 80%. Further, when producing a polyurethane elastomer sheet, a dimensional stability is inferior and fish eyes are formed, making it impossible to stably provide a good-quality sheet; moldability is still insufficient.

[0012] JP-B-1030945 describes the preparation of a non-woven fabric of spun polyurethane elastomer fibers. The preparation comprises spraying a high temperature gas stream on melt spun thermoplastic polyurethane elastomer for division into continuous filaments of average diameter below 30 microns. The filaments are heaped up into a sheet and are bonded to one another at points of contact by their own adhesive power.

[0013] JP-A-3019952 describes the obtaining of a fabric by laminating melt spun polyurethane elastic filament without collecting and gathering. The contact point of the laminated filaments is joined with the film itself. Preferable polyurethane elastic material to be used is known melt spinnable thermoplastic polyurethane elastomer obtained from a low melting point polyol having a molecular weight of 500 to 6000, an organic diisocyanate having a molecular weight less than 500 and a chain extending agent having a molecular weight less than 500 such as a glycol, amino alcohol or triol.

[0014] JP-A-6102851 and JP-B-63057447 describe the preparation of a thermoplastic polyurethane having good fusion flowability. The preparation comprises reacting an organic diisocyanate with a high molecular weight diol to obtain a pre-polymer, mixing the pre-polymer with a residual amount of organic diisocyanate, kneading the mixture with a low molecular weight compound and stopping the reaction when the melt flow ratio (mfr) value at 220°C becomes 100 or less. The diol has an average molecular weight of 500 to 3000, and the low molecular weight compound contains two active hydrogen atoms and has a molecular weight of less than 500 such as an aliphatic diol, alicyclic diol or bis-hydroxyalkylbenzene.

[0015] US-A-3963679 describes a process for obtaining elastomeric polyurethane or polyureas without the formation of unwanted irregularities by exposing the mixture of reactants to a high velocity gradient by means of vigorously mixing kneading elements at an early phase of the reaction while the viscosity of the reaction mixture is still low. The examples demonstrate that using this process causes the disappearance of numerous jelly-like inclusions which are seen in a sheet produced by extrusion through a sheeting die of 100 mm in width with a gap of 3 mm in height.

Disclosure of the Invention

[0016] It is an object of this invention to provide a process for preparing a thermoplastic polyurethane elastomer which has a high molecular weight and a narrow molecular-weight distribution and which contains a very small amount of polyurethane-based small grains.

[0017] Another object of this invention is to provide a process for preparing a polyurethane elastomer which is excellent in melt moldability and which can solve problems such as yarn breakage in spinning, etc. due to the small grains in particular.

[0018] Still another object of this invention is to provide an industrially advantageous process for continuously producing this thermoplastic polyurethane elastomer, which comprises subjecting a prepolymer composed of a high-molecular diol and an organic diisocyanate and a low-molecular diol to bulk melt polymerization at a relatively high temperature for a short period of time.

[0019] A still further object of this invention is to provide an apparatus for producing a polyurethane elastomer, which is suitable for preparing a polyurethane elastomer by practising the production process of this invention.

[0020] The other objects and advantages of this invention will be clarified from the following description.

[0021] The process of the present invention enables the production of a thermoplastic polyurethane elastomer which is characterized in that

(A) a number-average molecular weight is 160,000 to 200,000, a weight-average molecular weight is 300,000 to 450,000, and a weight-average molecular weight/number-average molecular weight ratio is in a range of 1.8 to 2.3, and

(B) the number of polyurethane-based small grains having a size of 5 to 50 μm at 20°C contained in the elastomer
The polyurethane elastomer has, as described above, the number-average molecular weight of 160,000 to 200,000, and the weight-average molecular weight of 300,000 to 450,000. The preferable range of the number-average molecular weight is 170,000 to 200,000, and the preferable range of the weight-average molecular weight is 350,000 to 450,000.

The weight-average molecular weight/number-average molecular weight ratio of the polyurethane elastomer is 1.8 to 2.3. The preferable range of said ratio is 1.9 to 2.1.

The polyurethane elastomer contains only 500 or less polyurethane-based small grains per kilogram of the polyurethane. The polyurethane-based small grains shall be understood not to include additives being added to polyurethane, e.g., a filler and a desulfurant such as titanium oxide, and an undissolved material (dust) being incorporated without intention. The number of the small grains is preferably 200 or less, more preferably 100 or less per kilogram of the polyurethane.

According to the present inventors' investigations, it has been found that the polyurethane-based small grains are (a) crystalline particles which have a size of 5 to 50 μm at 20°C and melt at a melting point (Tm) of a homopolymer composed only of a hard segment making up the polyurethane substrate, or (b) gel-like particles which have a size of 5 to 50 μm at 20°C and do not melt at the above melting point (Tm).

The thermoplastic polyurethane elastomer is a soft material which is usually rubbery at room temperature. This can be confirmed by observation with a polarization microscope. It shows that a crystallized portion of a hard segment in the polyurethane elastomer is color-formed (birefringence) and disappears when heated to a crystal melting point of a polymer composed of the hard segment. A mass having a size of 5 μm or more in the crystallized portion of the hard segment (hereinafter referred to as "a crystalline mass of the hard segment") has a crystal melting point of 245 to 260°C in case of, e.g., 1,4-butanediol and 4,4'-diphenylmethane diisocyanate. Therefore, even when melt extrusion molding, e.g., melt spinning is conducted usually at 200 to 240°C, said mass remains as such in fibers or films and becomes a small grain of a core of the small grain, which causes troubles such as yarn breakage in spinning, insufficient unwinding of wound yarns due to notable hang-up, holing or weft bar of a knit fabric, formation of fish eyes in a film, etc. Further, a large crystalline mass having a size of about 40 μm or above, for example, which does not pass a filter causes increase in filtration pressure. On the other hand, gel-like particles having a size of 5 μm or more, which do not disappear even at the above crystal melting point, are less color-formed than the crystalline mass and are amorphous in most cases. The gel-like particles remain as an undissolved material when dissolved in a solvent of a polyurethane elastomer. The gel-like particles being almost the same as the size of the filter pore can pass through the filter, but like the crystalline mass, become small grains or cores of small grains in the fiber, the film, etc., which gives rise to troubles. On the other hand, the color-formed particles having a size of less than 5 μm does not arouse the above troubles.

The polyurethane elastomer is produced by bulk melt polymerization.

In accordance with this invention, there is provided a process for producing a polyurethane elastomer, which comprises:

1. Feeding a high-molecular weight diol having an average molecular weight of 500 to 3000 and an organic diisocyanate in desired amounts to a high-speed mixer which is rotating at a speed of 500 to 4,000 rpm and mixing them thoroughly, the molar ratio of the organic diisocyanate to the high-molecular weight diol being 4:1 to 2:1.
2. Feeding the resulting monomer mixture to a reaction cylinder fitted with one or more perforated plates, the mixture being fed to the upper portion of the cylinder to cause the mixture to flow down, during which said mixture is reacted at a temperature of 50 to 120°C to form a polyurethane prepolymer, and
3. Subjecting the polyurethane prepolymer and a desired amount of a low-molecular weight diol having an average molecular weight of less than 500 to a bulk melt polymerization at a temperature of 240 to 270°C, while thoroughly mixing them, for 1 to 10 minutes in a twin screw extruder which is rotating at a speed of 30 to 300 rpm in such proportions that a molar ratio of total amount of hydroxyl groups of the high-molecular weight diols/amount of isocyanate groups of the diisocyanate is 0.95 to 1.05, to form polyurethane.
Preferred examples of the high-molecular diol include a polyester diol, a polyether diol, a polycarbonate diol and a polyester ether diol. They may be used either singly or in admixture of two or more. Examples of the polyester diol include polycondensed products of ethylene glycol, propylene glycol, 1,4-butanediol, 1,5-pentanediol, 1,6-hexanediol, neopentyl glycol, 2-methylpropandiol and the other low-molecular diols and low-molecular dicarboxylic acids such as glutaric acid, adipic acid, pimelic acid, suberic acid, sebacic acid, terephthalic acid and isophthalic acid; and poly-lite esters obtained by ring opening polymerization of lactones, such as polycaprolactone glycol, polypropylene glycol and polyvalerolactone glycol. Examples of the polyester diol include polyalkylene ether glycols such as polyethylene ether glycol, polypropylene ether glycol, polytetramethylene ether glycol and polyhexamethylene ether glycol. Examples of the polycarbonate diol include polycarbonate diols obtained by condensing low-molecular diols, e.g., aliphatic or alicyclic diols such as 1,4-butanediol, pentanediol, 1,6-hexanediol, octanediol and decanediol with diphenyl carbonate or phosgene.

Preferred examples of the polyester ether diol include polyalkylene ether diols such as polyethylene ether glycol, polypropylene ether glycol, polytetramethylene ether glycol and polyhexamethylene ether glycol.

The average molecular weight of these high-molecular diols is 500 to 3,000, more preferably 500 to 2,500. When the average molecular weight is too low, compatibility with the organic isocyanate is too good, decreasing elasticity of the resulting polyurethane. On the other hand, when the average molecular weight is too high, compatibility with the organic isocyanate is so poor as not to be well conduct mixing in the polymerization step, and a gel-like mass is formed, making it hard to obtain stable polyurethane.

The low-molecular diol is a diol having a molecular weight of less than 500. Preferred examples of the low-molecular diol include aliphatic and aromatic diols such as ethylene glycol, propylene glycol, 1,4-butanediol, 1,5-pentanediol, 1,6-hexanediol and 1,4-bishydroxyethylbenzene. They may be used either singly or in combination.

In the process of this invention, the above starting materials, a polyurethane prepolymer composed of the high-molecular diol and the organic isocyanate is first prepared and then the polyurethane prepolymer is reacted with a low-molecular diol.

The polyurethane prepolymer is formed by

1. feeding the high-molecular diol and the organic isocyanate in given amounts to a high-speed mixer, and mixing them thoroughly; and
2. feeding the resulting monomer mixture into a reaction cylinder fitted with one or more perforated plates from its upper portion to cause it to flow down, during which the mixture is allowed to react to form a polyurethane prepolymer.

The organic isocyanate/high-molecular diol molar ratio is 4.1 to 2.1, more preferably 3.5 1 to 2.5 1. These starting materials are fed to the high-speed mixer at the given molar ratio, using a metering pump, for example. That is, these starting materials are mixed with a mixer which is rotated at high speed of 500 to 4,000 rpm, more preferably 1,000 to 3,000 rpm. The starting materials uniformly mixed with the high-speed mixer are fed into the reaction cylinder fitted with one or more perforated plates from its upper portion and are allowed to react during flowing down, to form a polyurethane prepolymer. The perforated plate has an opening area ratio of 3 to 60 %, more preferably 5 to 40 %.

L/D of the reaction cylinder is preferably 2 to 30, more preferably 3 to 20.

It is advisable that a baffle cone is mounted under the perforated plate group in the reaction cylinder to increase plug flow property (rectification). It is advisable that an outer diameter of the baffle cone is 1/10 to 2/10, preferably 1/3 to 1/2 of the inner diameter of the reaction cylinder in the mounting position.

An average residence time in the reaction cylinder is preferably 15 to 120 minutes, more preferably 30 to 80 minutes. A reaction temperature is preferably 50 to 120°C, more preferably 70 to 90°C. It is advisable that feeding of the reactants to the reaction cylinder is controlled such that a level on the uppermost perforated plate, for example, becomes a predetermined value. It is advisable that the feeding of the given amounts of the high-molecular diol and the organic isocyanate to the high-speed mixer is controlled by this level of the monomer mixture in the reaction cylinder.

The process of this invention is carried out by subjecting the above-obtained polyurethane prepolymer and the low-molecular diol to the bulk melt polymerization.

The polyurethane prepolymer and the low-molecular diol are used in such proportions that the molar ratio (R ratio) of total amount of hydroxyl groups of the high-molecular and low-molecular diols/amount of isocyanate groups of the organic isocyanate is 0.95 to 1.05. The preferable range of the molar ratio is 1.00 to 1.05.

When the R value is deviated from said range, the formed polyurethane elastomer is not satisfactory in physical properties or melt moldability, and there is a high possibility that many gel-like particles are contained in the elastomer. Thus, it is undesirable.

The polyurethane prepolymer and the low-molecular diol are fed to a screw extruder. It is also possible to
preliminarily mix the polyurethane prepolymer and the low-molecular diol to form into a uniform mixture with the high-speed mixer. As the screw extruder, a twin-screw extruder is suitable. The number of rotations is preferably 30 to 300 rpm, more preferably 60 to 200 rpm. The cylinder temperature of the polymerization zone is 240 to 270°C, preferably 245 to 265°C. It is advisable that at least one zone of the cylinder is set at a temperature near the melting point of a crystalline mass to disperse the formed crystalline mass by kneading. The top extrusion pressure is preferably 20 to 45 kg/cm². Thus, there is provided a high-quality polyurethane elastomer having less unevenness in molecular weight and containing a very small amount of grains. An average residence time varies depending on a screw or L/D, but is preferably 1 to 10 minutes, more preferably 2 to 6 minutes. Hence, the product is continuously extruded from an outlet in such short period of time. It is advantageous that the bulk polymerized polyurethane elastomer is, for example, led to water, rapidly cooled and pelletized.

[0044] In the reaction of the prepolymer and the low-molecular diol, a known polymerization catalyst such as dibutyltin laurate or N-methylmorphorine can also be used upon dispersing it in the low-molecular diol.

[0045] In general, a polyurethane elastic yarn is produced by a wet spinning method or a dry spinning method. Examples using a melt spinning method are relatively few. This is presumably because the melt spinning method involves problems that the conventional polyurethane elastomer is liable to form small grains; that since heat stability in melting is generally poor, long-term stable operation is difficult; and that since the polyurethane elastomer obtained by the melt spinning has poor heat resistance, restoration from deformation at high temperatures is insufficient.

[0046] There is a method in which after a polyisocyanate compound is added and mixed, the mixture is melt spun to improve thermal properties of urethane yarns obtained by melt spinning (see Japanese Patent Publication Sho 58-46,573 (No. 46,573/1983)). In this invention, the content of active isocyanate groups in polyurethane jetted from a kneading extruder is 0.5 % by weight or more, preferably 0.5 to 1.1 % by weight. When it is less than 0.5 % by weight, heat resistance is not improved enough. On the other hand, when it exceeds 1.1 % by weight, spinability decreases, urethane yarns wound up are liable to hang up undesirably. The content of the active isocyanate groups in polyurethane is measured by dissolving polyurethane in dimethyl sulfoxide (DMSO), reacting the solution with excess dibutylamine, and titrating the remaining dibutylamine with an ethanol solution of hydrochloric acid, and is expressed by wt. % in terms of [NCO]. A suitable method for increasing the content of the active isocyanate groups is a method in which a polyisocyanate compound is added to polyurethane, in which the polyaddition reaction has completed and the content of the isocyanate groups has decreased, either directly or after pelletized and remelted, and the mixture is then melt spun. The thus-spun urethane yarns cause allophanate crosslinking during ageing at room temperature for more than one day to improve heat resistance.

[0047] The polyisocyanate compound used in this invention is a compound having at least 2 isocyanate groups in one molecule, and can be formed, for example, by adding 2 moles or more of an organic diisocyanate to a polyol used to synthesize polyurethane, and reacting the mixture. Trifunctional or higher polyols are also usable. The number of isocyanate groups contained in one molecule of the polyisocyanate compound is 2 to 4. Especially preferable is a disiocyanate compound containing 2 isocyanate groups. When the number of the isocyanate groups is too large, a viscosity of the polyisocyanate compound becomes too high, and it is difficult to treat.

[0048] The polyisocyanate compound has an average molecular weight of usually 500 or more, especially preferably 1,000 to 3,000. When the average molecular weight is lower than the above limit, a steam pressure is high at the temperature in adding and mixing the molten polyurethane, which is inconvenient in operation. Moreover, since the activity is too high, properties tend to change during storage, causing a nonuniform reaction during spinning. On the other hand, when the molecular weight is too high, the amount of the polyisocyanate compound to be added has to be large, and spinning after mixing tends to be unstable. This is undesirable.

[0049] The amount of the polyisocyanate compound in this invention is preferably 3 to 20 % by weight, especially preferably 5 to 15 % by weight, based on the mixture of the thermoplastic polyurethane elastomer to be spun and the polyisocyanate compound. The polyisocyanate compound can be also mixed with the molten polyurethane using a device in which they are mixed with a rotary kneader, and then spun. It is more preferable to use a mixer having a stationary kneading element. Examples of the mixer having the stationary kneading element are known mixers such as "Static Mixer" of Kinnix Ltd, "Scare Mixer" of Sakura Seisakusho, "Honeycomb Mixer" of Tsubasa Kogyo K.K., and "TK-ROSSISG Mixer" of Tokushukakogyo K.K. The shape and number of these stationary kneading elements vary depending on the used conditions; these are selected such that kneading is sufficiently completed before jetting the polyurethane elastomer and the polyisocyanate compound from the spinneret.

[0050] The thus-produced polyurethane elastic yarns have improved heat resistance, and the heat resistance is improved from about 40 % to 60 to 90 % in evaluation terms of an elongation recovery rate at 190°C as will be later described.

[0051] The polyurethane elastomer produced by the process of this invention can be molded into various articles. When producing molded articles such as fibers or films, the polyurethane elastomer can contain known additives such as a coloring agent, an antioxidant, a lubricant, a weathering agent, a heat resistance imparting agent, etc. Such additives can be pulverized or melted and then injected into a bent port of a screw extruder via a micro-metering pump.
or dispersed in a prepolymer.

[0052] The polymerized polyurethane elastomer can be extruded into a sheet from an outlet die of the screw extruder, or extruded into a strand and then pelletized with a pelletizer. Especially with an underwater pelletizer, spherical pellets are stably obtained and good biting can be provided in a spinning step; it is thus desirable.

[0053] From the aspects of energy efficiency, a water content, dust mixing, etc., it is more preferable that the polymerized polyurethane elastomer is melt spun as such or formed into a nonwoven fabric by melt blowing.

[0054] In accordance with this invention, there is also provided an apparatus for producing a polyurethane elastomer which is suitable for practising the above process of this invention, particularly the process of this invention, which includes also the step of producing the polyurethane prepolymer composed of the high-polymer diol and the organic diisocyanate.

[0055] That is, an apparatus for producing the polyurethane elastomer of this invention comprises

(a) a high-speed mixer which rotates at a speed of 500 to 4000 rpm and is suitable for forming a monomer mixture by mixing a high-molecular diol with an organic diisocyanate.

(b) a reaction cylinder suitable for forming a polyurethane prepolymer by the reaction of the monomer mixture, said cylinder being fitted with one or more perforated plates, and

(c) a twin screw extruder which rotates at a speed of 30 to 300 rpm and is suitable for forming polyurethane by the bulk melt polymerization of the polyurethane prepolymer and a low-molecular diol.

[0056] The apparatus of this invention can further comprise a device for adding a polyisocyanate compound to the formed polyurethane and mixing them or an underwater pelletizer for pelletizing the formed polyurethane in water.

[0057] The apparatus of this invention will be described more specifically by referring to Figures 1 to 3 of the attached drawings.

[0058] In Figure 1, 1 is a reservoir for a high-molecular diol, and 2 is a reservoir for an organic diisocyanate. The high-molecular diol and the organic diisocyanate are fed to a high-speed mixer 3 and well mixed. The resulting monomer mixture is then fed to a reaction cylinder 4 fitted with at least 1 perforated plate 5 (eight perforated plates in the drawing). Figure 2 shows an example of the perforated plate. Preferably, a baffle cone 7 is provided in a lower portion of the perforated plate 5. Feeding of the high-molecular diol from the reservoir 1 and the organic diisocyanate from the reservoir 2 to the reaction cylinder 4 is preferably controlled by a level controlling zone 8 on the basis of a reactant level 6 in the reaction cylinder 4. The polyurethane prepolymer from the reaction cylinder 4 and the low-molecular diol from a reservoir 9 for a low-molecular diol are mixed preferably with the high-speed mixer and then introduced into a twin-screw extruder 10. In the twin extruding screw, the bulk melt polymerization in the process of this invention is carried out as described above. The polyurethane elastomer from the twin extruding screw is pelletized preferably with an underwater pelletizer and as required, introduced into a centrifugal dehydrator 12 to separate the pellets from water.

[0059] In Figure 3, after a polyisocyanate 24 is added to the polyurethane elastomer formed in an twin extruding screw 22, they are uniformly mixed with a stationary kneading element 27, and then wound up as a filament 31 with a melt spinning device. That is, the prepolymer and the low-molecular diol 21 are fed from a feed opening of the twin extruding screw 22 to form a polyurethane elastomer. Part of the polyurethane elastomer is pelletized with a pelletizer 23 as required. To the polyurethane elastomer, a polyisocyanate 24 is added via a metering pump 25 and a filter 26, and they are uniformly mixed with the stationary kneading element 27. Subsequently, the resulting mixture is formed into a polyurethane elastic filament 31 with a melt spinning device comprising a spinning head 28, a metering pump 29 and a spinning nozzle 30, and wound up on a roll 32.

[0060] The polyurethane elastomer is, either directly or after pelletized, molded into various articles as stated above. In particular, fibers made of the polyurethane elastomer are extremely high-quality because the number of small grains contained in the elastomer is extremely small. Further, this invention allows the continuous production of the high-quality polyurethane elastomer stably for a short period of time and enables continuous operation for a long period of time (20 days or more). Still further, in producing the fibers, for example, yarn breakage in spinning owing to small grains is remarkably reduced, a spinneret life becomes longer, and the yield is improved to 85 to 96%.

[0061] Fibers formed of such polyurethane elastomer can be used in combination with the other fibers and provide knitted articles such as stockings, swimming suits, inner wear, etc. in which holing, weft bar, etc. are greatly improved. Further, the fibers having improved heat resistance allows high-temperature dyeing or false-twisting, leading to widening of their usage.

**Brief Description of Drawings**

[0062] Figure 1 is an example of an apparatus for producing a polyurethane elastomer.

[0063] Figure 2 is an example of a perforated plate used in the apparatus.

[0064] Figure 3 is an example of a suitable apparatus for directly producing fibers having improved heat resistance.
from the polyurethane elastomer.

**Examples**

[0065] The following Examples illustrate this invention more specifically. This invention is not limited to these Examples at all.

[0066] In this invention, small grains and a viscosity are measured and defined as follows.

**Small grains:**

[0067] Small grains have a diameter of 5 to 50 μm. The small grains are measured as follows. A fiber (a diameter thereof is usually about 20 μm to 70 μm) is run between a pair of roll bearings, and variation in interval thereof-between is detected and measured with a strain gauge. Small grains give a diameter of 100 μm or more. Regarding a sheet and a film (a thickness thereof is usually about 20 μm to 600 μm) it can be viewed with a microscope. Small grains having a diameter of 5 to 50 μm or more are counted.

**Molecular weight:**

[0068] Absorption intensity is measured at 280 nm of UV light in a concentration of 0.35 % by weight at a column temperature of 50°C in the presence of dimethylformamide as a solvent using a gel permeation chromatography equipped with a 710 model fully automatic sample processor manufactured by Waters Co., Ltd., a 590 model multipurpose pump manufactured by Waters Co., Ltd., a 481 model wavelength variable UV portion detector manufactured by Waters Co., Ltd., and K-80M and KD-802 model filling columns manufactured by Showa Denko K.K.

[0069] As standard samples, polystyrenes (weight-average molecular weights = 1,951, 4,000, 20,800, 33,000, 111,000, 225,300, 498,000, 867,000, 2,610,000) were used. Number-average molecular weights and weight-average molecular weights of the measured samples correspond to those of the standard polystyrenes.

**Example 1:**

[0070] Preliminary, 65.2 parts by weight of a polyester diol (polylhexanediol adipic acid ester: PHA, a molecular weight 2,000) obtained by polycondensation of adipic acid and 1,6-hexanediol and 26.5 parts by weight of 4,4’-diphenylmethane diisocyanate (MDI) were melted at 80°C respectively. These melts were mixed with a high-speed mixer and allowed to react for 2 hours with a stirrer-equipped preparation vessel kept at 80°C to produce a prepolymer. Separately, 1,4-butanediol (1,4-BD) as a low-molecular diol was prepared in a reservoir kept at 80°C. To a twin-screw extruder (rotating in the same direction) having a diameter of 45 mm, the prepolymer was fed from the preparation vessel at a rate of 18.7 kg/hr and the low-molecular diol from the reservoir at a rate of 1.3 kg/hr respectively via a metering pump to conduct polymerization. The cylinder temperatures of the twin-screw extruder were 160°C, 200°C, 220°C, 250°C and 210°C in this order from a starting material feed opening. The extrudate was discharged from a two-hole spinneret having a diameter of 2.4 mm with the number of screw rotations of 150 rpm at an extrusion pressure of 35 kg/cm² (using a 60 μm filter) in an average residence time of 4 minutes, and pellets could be obtained stably with an underwater pelletizer.

[0071] Then, the pellets were dehydrated and dried to a water content of 80 ppm or less. Melt spinning of 30 denier 1 filament x 8 was then conducted with a single screw extruder having a diameter of 25 mm at a feed temperature of 190°C through a 40 μm spinning filter. Yarn breakage in spinning was extremely few. When small grains were measured on the resulting polyurethane elastomer monofilament, it was found that the polyurethane elastomer contained a very small amount of the small grains. The results are shown in Table 1.

**Example 2:**

[0072] A polyurethane elastomer monofilament was produced in the same manner as in Example 1 except that the high-molecular diol was changed to a polyether diol (polytetramethylene glycol: PTMG, a molecular weight 1,000) obtained by ring opening polymerization of tetrahydrofuran and that all the cylinder temperatures were elevated by 10°C. The results are shown in Table 1.

**Example 3:**

[0073] A polyurethane elastomer filament was produced in the same manner as in Example 1 except that the high-molecular diol was changed into polyhexamethylene-1,6-carbonate glycol (a molecular weight 2,000) and that all the
cylinder temperatures were elevated by 5°C. The results are shown in Table 1.

Comparative Example 1:

[0074] The polyol (13.3 kg/cm²) having the molecular weight of 2,000, 5.4 kg/cm² of MDI and 1.3 kg/cm² of 1,4-BD in Example 1 were continuously fed to a twin-screw extruder, and polymerized (a one-shot process) upon setting the cylinder temperatures at 75°C, 165°C, 240°C, 240°C and 210°C. Using the pellets of the resulting polyurethane elastomer, a monofilament was produced as in Example 1. The results are shown in Table 1.

Comparative Example 2:

[0075] The prepolymer (18.7 parts) and 1.3 parts of 1,4-BD in Example 1 were fed to a kneader heated at 90 to 150°C. The mixture was reacted for 30 minutes with stirring to obtain a polyurethane powder (a kneader method). The polyurethane powder was heat-treated at 95°C for 16 hours, then fed to a twin-screw extruder having a diameter of 45 mm and pelletized. The cylinder temperatures of the screw were 160°C, 190°C, 210°C, 230°C and 210°C in this order from the feed opening. Using the pellets of the resulting polyurethane elastomer, a monofilament was produced as in Example 1. The results are shown in Table 1.

Comparative Example 3:

[0076] A polyurethane elastomer and a monofilament thereof were produced in the same manner as in Example 1 except that the R ratio was changed to 1.07. The resulting monofilament contained a large amount of small grains having a gel-like substance as a core, and yarn breakage in spinning occurred a bit frequently. The results are shown in Table 1.

Example 4:

[0077]

1. Seventy (70) parts by weight of a polylol having a molecular weight of 2,000, which was a mixture comprising a polyester diol (polybutanediol adipic acid ester: PBA) of adipic acid and 1,4-butanediol and a polyester diol (polyhexanediol adipic acid ester: PHA) of adipic acid and 1,6-hexanediol (a PBA-PHA mixing molar ratio = 1:1), and 30 parts by weight of 4,4'-diphenylmethane diisocyanate (MDI) were prepared. To a high-speed mixer rotating at 3,000 rpm, the above polylol was fed at a rate of 13.4 kg/hr and MDI at a rate of 5.4 kg/hr from respective reservoirs held at 80°C with a metering pump, and they were mixed in the mixer. Subsequently, the mixture was continuously fed to a reaction cylinder (an inner temperature 80°C) having an inner diameter of 150 mm and a height of 1,400 mm and fitted with 5 perforated plates having a perforation ratio of 10%. The prepolymer (an average residence time 60 minutes) was discharged at a rate of 18.8 kg/hr from a lower portion. The level was controlled by feeding the polylol and MDI to the high-speed mixer such that said level became fixed at a height of 1,100 mm. The amount of NCO groups of the resulting prepolymer was (147 ± 3) x 10^-5 mol/g.

2. 1,4-Butanediol (1,4-BD) was used as the low-molecular diol, and the temperature was maintained at 80°C. The prepolymer in the above (1) and 1,4-BD were fed from a metering pump to a high-speed mixer rotating at 2,000 rpm, at feed rates of 19 kg/hr and 1 kg/hr respectively. Then, the uniform mixture was fed to a twin-screw extruder (rotating in the same direction) having a diameter of 45 mm, and polymerized. The cylinder temperatures of the twin-screw extruder were 200°C, 230°C, 260°C and 290°C in this order from a starting material feed opening. The molten polyurethane elastomer was extruded in water with the number of screw rotations of 100 rpm at an extrusion pressure of 35 kg/cm² from a 2-hole spinneret having a diameter of 2.4 mm, provided thereinside with a heater and having a surface coated with ceramics, and then immediately the extrudate was cut with an underwater pelletizer that conducted cutting with a rotary cutter having 3 blades to afford spherical pellets.

[0078] Subsequently, the pellets were centrifugally dehydrated and dried to a water content of 80 ppm or less, and then melt spinning of 30 denier 1 filament x 8 was carried out with a single screw extruder having a diameter of 25 mm at a head temperature of 190°C. Small grains were measured on the resulting polyurethane elastomer monofilament. As a result, the polyurethane elastomer was found to contain a very small amount of the small grains. The results are shown in Table 2.

Comparative Example 4:

[0079] A polyurethane elastomer monofilament was produced in the same manner as in Example 4 except that the cylinder temperatures of the twin-screw extruder were changed into 200°C, 220°C, 230°C and 230°C. The results are shown in Table 2.

Example 5:

[0080] The melt of the polyurethane elastomer polymerized in Example 4 was led as such to a melt blow spinning device having slits for jetting a heated gas in both sides of nozzles having a diameter of 0.8 mm and mounted in a row, and injected at a head temperature of 240°C and a rate of 0.5 g/min in each nozzle. Air heated at 200°C was jetted from the slits at a pressure of 3.5 kg/cm² to conduct attenuation. The attenuated filament was collected on a conveyor made of a 30-mesh wire net and located 25 cm below the nozzles, and was taken off between rollers to obtain a nonwoven fabric having a weight of 50 g/m² (see Example 2 of Japanese Patent Publication Hei 1-30,945 (No. 30,945/1989)).

[0081] In the nonwoven fabric, monofilaments of the polyurethane elastomer fibers were laminated in a spread state, and intertwined points between the monofilaments were bound with each other by fusion. When small grains were measured, the number thereof was found to be as small as about 80 per kilogram. The fiber was composed of the narrow, uniform monofilaments having a diameter of about 20 μm.

Example 6:

[0082] The dried pellets in Example 4 were melted with an extruder and then extruded onto a quenching rotary drum from a slit die of 240°C to form a sheet having a film thickness of 0.6 mm.

[0083] When small grains of the resulting sheet were measured, the number thereof was found to be as small as about 80 per kilogram. Thus, the sheet was a good-quality sheet.

Example 7:

Dihydroxy poly-ε-caprolactone (1,500 parts) having a hydroxyl number of 150 and 1,000 parts of p,p-diphenylmethane diisocyanate were reacted at 80°C to obtain a viscous polyisocyanate compound. The polyisocyanate compound had an isocyanate content of 6.74 % and a molecular weight of 1,250.

The polyurethane elastomer polymerized in Example 4 was introduced into the apparatus shown in Figure 3, and part of the elastomer divided at the end of the extruder was injected into water from a spinneret having a diameter of 2.4 mm, and pelletized. After injecting the polyisocyanate compound, the other part was kneaded with a mixer having a stationary kneading element, weighed with a gear pump and spun into a monofilament having a denier of 40 at a take-up speed of 500 m/min, using a nozzle having a diameter of 1.0 mm. Spinning was conducted by changing the amount of the polyisocyanate compound added to polyurethane. The results are shown in Table 3.

The qualities of the filaments were measured after allowed to stand at room temperature for 2 days after spinning. The number of small grains in the filament was good and 1 or less per 1,000 m in each case. Incidentally an elongation recovery rate at 190°C based on which a heat resistance of the polyurethane elastomer fiber was evaluated was measured as follows.

(1) One hundred millimeters of the polyurethane elastomer fiber aged at room temperature for 2 days after spinning were left to stand in an oven of 190°C in a state elongated to 130 mm.
(2) The fiber was left to stand at 20°C for 2 minutes in a state elongated to 130 mm.
(3) Elongation was released, and 2 minutes later, the fiber length L (mm) was measured.

\[
\text{elongation recovery rate at 190°C(%) = \frac{(130 - L) \times 100}{(130 - 100)}}
\]

Claims

1. A process for producing a polyurethane elastomer, which comprises

   (1) feeding a high-molecular weight diol having an average molecular weight of 500 to 3000 and an organic disiocyanate in desired amounts to a high-speed mixer which is rotating at a speed of 500 to 4,000 rpm and mixing them thoroughly, the molar ratio of the organic disiocyanate to the high-molecular weight diol being 4:1 to 2:1,

   (2) feeding the resulting monomer mixture to a reaction cylinder fitted with one or more perforated plates, the mixture being fed to the upper portion of the cylinder to cause the mixture to flow down, during which said mixture is reacted at a temperature of 50 to 120°C to form a polyurethane prepolymer, and

   (3) subjecting the polyurethane prepolymer and a desired amount of a low-molecular weight diol having an average molecular weight of less than 500 to a bulk melt polymerization at a temperature of 240 to 270°C, while thoroughly mixing them, for 1 to 10 minutes in a twin screw extruder which is rotating at a speed of 30 to 300 rpm in such proportions that a molar ratio of total amount of hydroxyl groups of the high-molecular weight diols/amount of isocyanate groups of the diisocyanate is 0.95 to 1.05, to form polyurethane.

2. The process of claim 1 wherein the feeding of the desired amounts of the high-molecular weight diols and the organic disiocyanate in step (1) to the high-speed mixer is controlled by a level of the monomer mixture in the reaction cylinder in step (2).

3. The process of claim 1 or 2 wherein step (2) is carried out by further providing a baffle cone under the perforated plate of the reaction cylinder.

4. The process of any one of claims 1 to 3, wherein the polyurethane elastomer obtained is characterized by

   (a) having a number-average molecular weight of from 160,000 to 200,000, a weight-average molecular weight of from 300,000 to 450,000, and the weight-average molecular weight/number-average molecular weight ratio is from 1.8 to 2.3, and

   (b) the number of polyurethane-based small grains having a size of 5 to 50 μm at 20°C contained in the elastomer being 500 or less per kilogram of polyurethane.

5. The process of claim 4, wherein the number of small grains contained in the elastomer is 200 or less per kilogram of polyurethane.

6. The process of claim 4 or 5, wherein the small grains are (a) crystalline particles which have a size of 5 to 50 μm at 20°C and melt at a melting point of a homopolymer composed only of a hard segment making up the polyurethane substrate, or (b) gel-like particles which have a size of 5 to 50 μm at 20°C and do not melt at the melting point of the homopolymer composed only of the hard segment making up the polyurethane substrate.

7. An apparatus for producing a polyurethane elastomer according to the process of claim 1 comprising

   (a) a high-speed mixer which rotates at a speed of 500 to 4000 rpm and is suitable for forming a monomer
EP 0 592 668 B1

mixture by mixing a high-molecular weight diol and an organic diisocyanate,
(b) a reaction cylinder suitable for forming a polyurethane prepolymer by the reaction of the monomer mixture, said reaction cylinder being fitted with one or more perforated plates, and
(c) a twin screw extruder which rotates at a speed of 30 to 300 rpm and is suitable for forming polyurethane by the bulk melt polymerization of the polyurethane prepolymer and a low-molecular weight diol.

8. The apparatus of claim 7 further comprising

(d) an underwater pelletizer suitable for pelletizing the resulting polyurethane in water.

Patentansprüche

1. Verfahren zur Herstellung eines Polyurethanelastomer, umfassend:

(1) Einspeisen eines hochmolekulargewichtigen Diols mit einem mittleren Molekulargewicht von 500 bis 3000 und eines organischen Disiocyanats in gewünschten Mengen in einen Hochgeschwindigkeitsmischer, welcher mit einer Geschwindigkeit von 500 bis 4000 U/min rotiert, und gründliches Mischen derselben, wobei das Molverhältnis des organischen Disiocyanats zum hochmolekulargewichtigen Diol 4 : 1 bis 2 : 1 beträgt,

(2) Einspeisen der resultierenden Monomermischung in einen Reaktionszylinder, der mit einem oder mehreren perforierten Blöcken versehen ist, wobei die Mischung dem oberen Bereich des Zylinders eingespeist wird, um ein Herabfließen der Mischung zu bewirken, wobei währenddessen die Mischung bei einer Temperatur von 50 bis 120°C umgesetzt wird, um ein Polyurethan-Prepolymer zu bilden, und

(3) Untерziehen des Polyurethan-Prepolymeren und einer gewünschten Menge eines nieder- oder mittleren Molekulargewichts von weniger als 500 einer Schmelzpolymerisation in Masse bei einer Temperatur von 240 bis 270°C, während sie gründlich gemischt werden, während 1 bis 10 Minuten in einem Doppel-Schnecken-Extruder, der mit einer Geschwindigkeit von 30 bis 300 U/min rotiert, und zwar in solchen Verhältnissen, daß das Molverhältnis der Gesamtmenge an Hydroxygruppen der hochmolekulargewichtigen Diol/Menge an Isocyanatgruppen des Disiocyanats 0,95 bis 1,05 beträgt, um Polyurethan zu bilden.

4. Verfahren gemäß mindestens einem der Ansprüche 1 bis 3, wobei das erhaltene Polyurethanelastomer gekennzeichnet ist durch:

(a) ein zahlenmittleres Molekulargewicht von 160.000 bis 200.000, ein gewichtsmittleres Molekulargewicht von 300.000 bis 450.000 und ein Verhältnis von gewichtsmittlerem Molekulargewicht/zahlenmittelarem Molekulargewicht von 1,8 bis 2,3, und

(b) die Anzahl an auf Polyurethan basierenden kleinen Körnchen mit einer Größe von 5 bis 50 μm, die in dem Elastomer enthalten sind, bei 20°C, welche 500 oder weniger pro Kilogramm Polyurethan beträgt.

5. Verfahren gemäß Anspruch 4, wobei die Anzahl an kleinen Körnchen, die in dem Elastomer vorliegen, 200 oder weniger pro Kilogramm Polyurethan beträgt.

6. Verfahren gemäß Anspruch 4 oder 5, wobei die kleinen Körnchen (a) kristalline Teilchen mit einer Größe von 5 bis 50 μm bei 20°C sind und bei einem Schmelzpunkt eines Homopolymeren schmelzen, das nur aus einem harten Segment besteht, welches das Polyurethan-Substrat aufbaut, oder (b) gelartige Teilchen, welche eine Größe von 5 bis 50 μm bei 20°C besitzen und nicht bei dem Schmelzpunkt des Homopolymeren, das nur aus dem harten Segment, das das Polyurethan-Substrat aufbaut, besteht, schmelzen.
7. Vorrichtung zur Herstellung eines Polyurethanolastomeren gemäß dem Verfahren von Anspruch 1, umfassend:
   
   (a) einen Hochgeschwindigkeitsmischer, welcher bei einer Geschwindigkeit von 500 bis 4.000 UpM rotiert und zur Bildung einer Monomermischung geeignet ist, indem er ein hochmolekulargewichtiges Diol und ein organisches Disocyanat mischt,
   
   (b) einen Reaktionszylinder, der zum Bilden eines Polyurethan-Prepolymeren durch die Reaktion der Monomermischung geeignet ist, wobei der Reaktionszylinder mit einer oder mehreren perforierten Blechen ausgestattet ist, und
   
   (c) einen Doppel-Schnecken-Extruder, welcher mit einer Geschwindigkeit von 30 bis 300 UpM rotiert und zum Bilden von Polyurethan durch die Schmelzpolymerisation in Masse des Polyurethan-Prepolymeren und eines niedermolekulargewichtigen Diols geeignet ist.

8. Vorrichtung gemäß Anspruch 7, ferner umfassend:
   
   (d) einen Unterwasser-Pelletisierer, geeignet zur Pelletisierung des resultierenden Polyurethans in Wasser.

Revendications

1. Procédé de fabrication d’un élastomère de polyuréthane, qui comprend les étapes consistant
   
   (1) à introduire un diol de haut poids moléculaire, ayant un poids moléculaire moyen de 500 à 3000, et un disocyanate organique, en des quantités souhaitées, dans un mélangeur à haute vitesse qui tourne à une vitesse de 500 à 4 000 tr/min., et à les mélanger parfaitement, le rapport molaire du disocyanate organique au diol de haut poids moléculaire étant de 4:1 à 2:1,
   
   (2) à introduire le mélange de monomères résultant dans un cylindre de réaction muni d'une ou plusieurs plaques perforées, le mélange étant introduit dans la partie supérieure du cylindre pour faire couler le mélange vers le bas, ledit mélange réagissant pendant ce temps à une température de 50 à 120 °C pour former un prépolymer de polyuréthane, et
   
   (3) à soumettre le prépolymer de polyuréthane et une quantité souhaitée d'un diol de bas poids moléculaire, ayant un poids moléculaire moyen inférieur à 500, à une polymérisation en masse à l'état fondu à une température de 240 à 270 °C, tout en les mélangeant parfaitement, pendant 1 à 10 minutes dans une extruduse à deux vis qui tourne à une vitesse de 30 à 300 tr/min., dans des proportions telles que le rapport molaire quantité totale de groupes hydroxyles du diol de haut poids moléculaire/quantité de groupes isocyanates du disocyanate soit de 0.95 à 1.05, pour former le polyuréthane.

2. Procédé selon la revendication 1, dans lequel l’introduction des quantités souhaitées du diol de haut poids moléculaire et du disocyanate organique dans l’étape (1) dans le mélangeur à haute vitesse est régie par le niveau du mélange de monomères dans le cylindre de réaction dans l’étape (2).

3. Procédé selon la revendication 1 ou 2, dans lequel l’étape (2) est effectuée en disposant en outre une chicane en forme de cône sous la plaque perforée du cylindre de réaction.

4. Procédé selon l’une quelconque des revendications 1 à 3, dans lequel l’élastomère de polyuréthane obtenu est caractérisé en ce que
   
   (a) il a un poids moléculaire moyen en nombre de 160 000 à 200 000, un poids moléculaire moyen en poids de 300 000 à 450 000, et le rapport poids moléculaire moyen en poids/poids moléculaire moyen en nombre est de 1.8 à 2.3, et
   
   (b) le nombre de petits grains à base de polyuréthane ayant une taille de 5 à 50 µm à 20 °C contenus dans l’élastomère est de 500 ou moins par kilogramme de polyuréthane.

5. Procédé selon la revendication 4, dans lequel le nombre de petits grains contenus dans l’élastomère est de 200 ou moins par kilogramme de polyuréthane.

6. Procédé selon la revendication 4 ou 5, dans lequel les petits grains sont (a) des particules cristallines qui ont une
7. Appareil pour fabriquer un élastomère de polyuréthanne selon le procédé de la revendication 1, comprenant
   (a) un malaxeur à haute vitesse qui tourne à une vitesse de 500 à 4 000 tr/min, et est apte à former un mélange de monomères par le mélange d'un diol de haut poids moléculaire et d'un diisocyanate organique,
   (b) un cylindre de réaction apte à former un prépolymère de polyuréthanne par la réaction du mélange de monomères, le dit cylindre de réaction étant muni d'une ou plusieurs plaques perforées, et
   (c) une extrudeuse à deux vis qui tourne à une vitesse de 30 à 300 tr/min, et est apte à former un polyuréthanne par la polymérisation en masse à l'état fondu du prépolymère de polyuréthanne et d'un diol de bas poids moléculaire.

8. Appareil selon la revendication 7, comprenant en outre
   (d) un granulateur immergé apte à granuler le polyuréthanne résultant dans de l'eau.
