Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
The invention relates to a semiconductor device, and more particularly to a high frequency and high speed field effect transistor with an improved Schottky gate structure.

EP-A2-522 952 shows such a semiconductor device comprising a Schottky gate structure. Such a HEMT can use different materials for the electron barrier layers. However, the height of the electron barrier layers of the Fermi level of the Schottky gate electrode as known from this document should be improved, in order to improve the characteristics of the HEMT.

Another semiconductor device is known from US-A-5 206 528. This document discloses a superlattice layer for a MISFET having a barrier height of the Schottky junction between gate electrode and the superlattice layer of about 1 eV.

Therefore, it is desired to improve the characteristics of the known semiconductor device.

Improvements and developments of high frequency and high speed field effect transistors made of compound semiconductors such as InP, InGaAs or other compound semiconductors including In are very important for revolution in semiconductor field. Compound semiconductors such as InP, InGaAs and other compound semiconductors including In are suitable for high frequency and high speed field effect transistors as having a property of a high electron mobility. Such high electron mobility field effect transistor showing high frequency and high speed performances have a Schottky gate contact. Namely, a gate electrode made of a metal has to be provided directly on a semiconductor layer so that the gate electrode is electrically separated from the semiconductor layers through the Schottky barrier. As well known, a semiconductor-metal contact or Schottky contact provides a conduction band discontinuity which serves as a potential barrier or Schottky barrier which prevents electrons acting as carriers to flow across the Schottky contact from the metal toward the semiconductor.

Using InP or InGaAs for high frequency and high speed transistors is disclosed in U.K. Mishra 1989 IEEE Transaction on Microwave Theory and Techniques, Vol. 37, No. 9 p. 1279. The structure of the device is as follows. A substrate is a semi-insulating InP substrate. A buffer layer made of InAlAs is formed on the semi-insulating InP substrate. A non-doped InGaAs layer is formed on the InAlAs buffer layer. An n-type InAlAs layer is formed on the non-doped InGaAs layer to form a hetero junction therewith. A non-doped InAlAs layer is formed on the n-type InAlAs layer. The above layers may sequentially be grown on the substrate. A gate electrode is provided on the non-doped InAlAs layer to form a Schottky contact therewith.

The non-doped InAlAs layer is provided to form a Schottky barrier in cooperation with the gate electrode. Such the Schottky barrier serve to prevent electrons acting as carriers to flow across the Schottky contact surface. Although the non-doped InAlAs layer is provided to suppress a gate leakage current, a Schottky barrier height is 0.55 eV which seems insufficient to suppress a gate leakage current in view of a voltage applied to the gate electrode. Much more high Schottky barrier is required to realize a sufficient suppression of the gate leakage current or to suppress electrons acting as carriers to move across the Schottky contact surface from the metal region of the gate electrode into the semiconductor region.

Another high electron mobility transistor is disclosed in May 1993 IEEE Electron Device Letters, Vol. 14, No. 5 pp. 259-261. The structure of the transistor is as follows. A semiconductor substrate is a semi-insulating InP substrate. An undoped InP layer having a thickness of 10 nanometers is formed on the semi-insulating InP substrate. An undoped InGaAs layer having a thickness of 20 nanometers is formed on the undoped InP layer. An undoped InAlAs layer having a thickness of 3 nanometers is formed on the undoped InGaAs layer. An n*-doped InAlAs layer having a thickness of 15 nanometers and an impurity concentration of 3x10^16 cm^-3 is formed on the undoped InAlAs layer. An undoped In_{0.75}Ga_{0.25}As layer having a thickness of 10 nanometers is formed on the n*-doped InAlAs layer. A recess etched cap layer made of n*-doped InGaAs having a thickness of 20 nanometers and an impurity concentration of 5x10^16 cm^-3 is formed on the undoped In_{0.75}Ga_{0.25}As layer. Source and drain electrodes are provided on the cap layer. A gate electrode is provided on an exposed surface of the undoped In_{0.75}Ga_{0.25}As layer in a recess portion. This transistor is so designed as to allow high frequency and high speed performances, while a Schottky barrier height is insufficient for a potential barrier to suppress a gate leakage current or prevent electrons acting as carriers to flow across the Schottky interface from the gate into the In_{0.75}Ga_{0.25}As layer. Much more high Schottky barrier is also needed.

To combat the above problems as to the gate leakage current, another Schottky gate structures were proposed and disclosed in the Japanese laid-open patent applications Nos. 64-41272 and 64-41273. The Japanese laid-open patent application No. 64-41272 describes inserting a superlattice structure of AlGaAs/AlInAs under the gate electrode in which the superlattice structure may serve as a potential barrier to suppress a gate leakage current or prevent electrons acting as carriers to flow across the Schottky contact surface into an A_{0.48}In_{0.52}As layer. The Japanese laid-open patent application No. 64-41273 also describes inserting an A_{0.4}Ga_{0.6}As layer under the gate electrode in which the superlattice structure may serve as a potential barrier to suppress a gate leakage current or prevent electrons acting as carriers to flow across the Schottky contact.
surface into an $A_{0.48}Ga_{0.52}As$ layer. The $A_{0.48}Ga_{0.52}As$ layer is required to have a thickness less than a critical thickness of approximately 10 nanometers in view of lattice matching. The superlattice structure of $AlGaAs/AlInAs$ is also required to have the sum of individual thicknesses of $AlGaAs$ layers less than a critical thickness which is very thin.

[0010] Typical structure of the above field effect transistors are illustrated in FIG. 1. The field effect transistor has an InP semi-insulating substrate 101. A layer 102 made of compound semiconductors including In is formed on the InP semi-insulating substrate 101. An InAlAs layer 103 is formed on the layer 102. An AlGaAs layer 104 is formed on the InAlAs layer 103. Recess etched n-doped InGaAs cap layers 107-1 and 107-2 serving as source and drain regions are formed on the AlGaAs layer 104. Source and drain electrodes 108-1 and 108-2 are provided on the source and drain regions 107-1 and 107-2. A gate electrode 109 is provided in a recess portion. The AlGaAs layer constitutes a potential barrier against electrons serving as carriers to prevent electrons from flowing across a Schottky contact from the gate electrode 109 into the InAlAs layer 103 so as to suppress a Schottky gate leakage current.

[0011] Such the Schottky barrier structures are engaged with the following problems in fabricating the device. The recess etching of the cap layer serving as source and drain regions is necessary to form such the Schottky barrier gate. Although the recess etching is continued until the barrier layer is exposed, it is difficult to control the recess etching to discontinue the recess etching just when a surface of the barrier layer is exposed in view of etching accuracy. Actually, the AlGaAs layer serving as a potential barrier seems suffer any damage from the recess etching process to form a recess portion in which the Schottky gate electrode is provided. The potential barrier layer once received any damage due to the recess etching process is no longer able to serve a potential barrier for suppressing a gate leakage current. This is the serious problem. The above superlattice structure serving as a potential barrier is also engaged with the same problem as described above. It would be required to develop a potential barrier structure in which the potential barrier layer is free from any damage due to the recess etching.

[0012] Another high electron mobility transistor having an potential barrier structure against holes as positive carriers in which a potential barrier layer is provided adjacent to a channel layer is disclosed in Inst. Phys. Conf. Ser. No 129 Chapter 12, pp. 941-942. The structure of high electron mobility transistor is as follows. A semiconductor substrate is a InP substrate. A buffer layer is formed on the semiconductor substrate. An InGaAs channel layer having a thickness of 40 nanometers is formed on the buffer layer. An n-doped InAlAs spacer layer having a thickness of 1.5 nanometers is formed in the InGaAs channel layer. An InAlAs hole barrier layer having a thickness of 3 nanometers is formed on the n-doped InAlAs spacer layer. An n-doped InAlAs spacer layer having a thickness of 1.5 nanometers is formed in the InAlAs hole barrier layer. An n^+ doped InAlAs layer having a thickness of 11 nanometers is formed on the n-doped InAlAs spacer layer. An n-doped InAlAs layer having a thickness of 20 nanometers is formed on the n^+ doped InAlAs layer. A recess etched cap layer made of InGaAs is formed on the n-doped InAlAs layer. Source and drain electrodes are provided on the cap layer. A gate electrode is provided on an exposure surface of the n-doped InAlAs in the recess portion to form a Schottky contact structure.

[0013] The InAlAs hole barrier layer is also able to serve as a potential barrier but against holes acting as carriers. The hole barrier layer serves merely as a potential barrier to hole carriers so as to prevent the hole carriers to flow out from the channel layer. For that purpose, it is required to provide the hole barrier layer adjacent to the channel layer. However, such the hole barrier layer would never be a potential barrier against electrons. Actually, it could readily be appreciated that the hole barrier adjacent to the channel layer is unable to suppress electrons to flow across the Schottky barrier from the Schottky gate electrode into the semiconductor layers. Although the electron barrier and the hole barrier fill the same role merely in view of suppressing a gate leakage current, the both barriers are on the bases of the completely different principles. Suppressing electron carriers to flow across the Schottky barrier contact surface from the Schottky gate into the semiconductor layer would completely be different technical viewpoint from suppressing hole carriers to flow out from the channel layer. In the former case the electron barrier is required to be provided adjacent to the Schottky gate contact, while in the later case the hole barrier is required to be provided adjacent to the channel layer.

[0014] The prior arts that inventors admitted neither describes nor teaches an ideal Schottky barrier structure to suppress electrons to flow across a Schottky contact surface from a Schottky gate electrode into a semiconductor layer in which a Schottky barrier layer provided adjacent to the Schottky contact is free from any damage due to a recess etching process.

[0015] It would, therefore, be required to develop a novel Schottky gate structure with an improved electron barrier involved in a high frequency and high speed field effect transistor of compound semiconductors.

[0016] Accordingly, it is a primary object of the present invention to provide a novel Schottky barrier structure having a sufficient potential barrier height to suppress electrons to flow across a Schottky contact surface from a Schottky gate electrode into a semiconductor layer.

[0017] It is a further object of the present invention to provide a novel Schottky barrier structure free from any disadvantages as described above.

[0018] It is moreover object of the present invention to provide a novel Schottky barrier structure to suppress any gate leakage current.
[0019] It is a furthermore object of the present invention to provide a novel high frequency and high speed field effect transistor involving an improved Schottky barrier structure to suppress electrons to flow across a Schottky contact surface from a Schottky gate electrode into a semiconductor layer.

[0020] It is still a further object of the present invention to provide a novel high frequency and high speed field effect transistor involving an improved Schottky barrier structure free from any damage due to a recess etching process.

[0021] It is yet another object of the present invention to provide a novel high frequency and high speed field effect transistor involving an improved Schottky barrier structure free from any disadvantages as described above.

[0022] It is another object of the present invention to provide a novel high frequency and high speed field effect transistor involving an improved Schottky barrier structure to suppress any gate leakage current.

[0023] The above and other objects, features and advantages of the present invention will be apparent from the following descriptions.

[0024] The present invention provides a high frequency and high speed field effect transistor having an improved Schottky barrier structure according to claim 1 which includes a Schottky gate electrode, a first layer being in contact with the Schottky gate electrode and being made of a first compound semiconductor and a second layer being in contact with the first layer and being made of a second compound semiconductor having a higher conduction band edge than a conduction band edge of the first compound semiconductor. The first compound semiconductor may comprise a compound semiconductor including In such as InAlAs. The second compound semiconductor may comprise AlAs, GaAs, GaP, In$_x$Al$_{1-x}$As (0<X<0.4), Al$_x$Ga$_{1-x}$As (0<X<1), Al$_x$Ga$_{1-x}$P (0<X<1), GaAs$_2$P$_1$ (0<X<1), AlAs$_2$P$_1$ (0<X<1), Al$_x$Ga$_{1-x}$As$_2$P$_1$ (0<X<1, 0<Y<1), or Al$_x$In$_{1-x}$As$_2$ (0<X<1, 0<Y<1, 0.48<X+Y<2). The second layer has a thickness of 5 nanometers. The first layer has a thickness in the range of from 5 nanometers to 10 nanometers.

[0025] The Schottky barrier structure further includes a third layer being in contact with the second layer which may be made of said first compound semiconductor and may include a fourth layer being in contact with the third layer and being made of the third compound semiconductor. The fourth layer has a thickness of 5 nanometers. The said third layer has a thickness of 5 nanometers.

[0026] Preferred embodiments of the present invention will hereinafter be described in detail with reference to the accompanying drawings.

[0027] FIG. 1 is a fragmentary cross sectional elevation view illustrative of the field effect transistor having the conventional Schottky barrier structure.

[0028] FIG. 2 is a fragmentary cross sectional elevation view illustrative of a novel high frequency and high speed field effect transistor having an improved Schottky barrier structure in a first embodiment according to the present invention.

[0029] FIG. 3 is a fragmentary cross sectional elevation view illustrative of a novel high frequency and high speed field effect transistor having an improved Schottky barrier structure in a second embodiment according to the present invention.

[0030] FIG. 4 is a fragmentary cross sectional elevation view illustrative of a novel high frequency and high speed field effect transistor having an improved Schottky barrier structure in a third embodiment according to the present invention.

[0031] FIG. 5 is a fragmentary cross sectional elevation view illustrative of a novel high frequency and high speed field effect transistor having an improved Schottky barrier structure in a fourth embodiment according to the present invention.

[0032] FIG. 6 is a fragmentary cross sectional elevation view illustrative of a novel high frequency and high speed field effect transistor having an improved Schottky barrier structure in a fifth embodiment according to the present invention.

[0033] FIG. 7 is a fragmentary cross sectional elevation view illustrative of a novel high frequency and high speed field effect transistor having an improved Schottky barrier structure in a sixth embodiment according to the present invention.

[0034] FIG. 8 is a fragmentary cross sectional elevation view illustrative of a novel high frequency and high speed field effect transistor having an improved Schottky barrier structure in a seventh embodiment according to the present invention.

[0035] FIG. 9 is a fragmentary cross sectional elevation view illustrative of a novel high frequency and high speed field effect transistor having an improved Schottky barrier structure in an eighth embodiment according to the present invention.

[0036] FIG. 10 is a fragmentary cross sectional elevation view illustrative of a novel high frequency and high speed field effect transistor having an improved Schottky barrier structure in a ninth embodiment according to the present invention.

[0037] FIG. 11 is a fragmentary cross sectional elevation view illustrative of a novel high frequency and high speed field effect transistor having an improved Schottky barrier structure in a tenth embodiment according to the present invention.

[0038] FIG. 12 is a diagram illustrative of an energy band gap profile across a Schottky contact surface of an improved Schottky barrier structure according to the present invention.

[0039] The present invention provides a novel Schottky barrier structure having a sufficient barrier height to prevent electrons serving as carriers to flow across a Schottky gate electrode into a semiconductor layer. The present invention also provides a novel
high frequency and high speed field effect transistor including an improved Schottky barrier structure having a sufficient barrier height to prevent electrons serving as carriers to flow across from a Schottky gate electrode into a semiconductor layer in which a barrier layer is provided relatively adjacent to a Schottky contact surface but be free from any damage due to a recess etching to form a recess portion in which a Schottky gate electrode is provided. The electron barrier layer having such a sufficient barrier height is provided not to be exposed through the recess portion or not directly contact with the Schottky gate electrode so as to keep the electron barrier layer from suffering any damage due to the recess etching process, while the electron barrier layer is required to be in a relatively adjacent position to the Schottky contact surface so as not only to ensure a prevention of electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode into semiconductor layers involving a channel layer. Even when a variation of etching depth in forming a recess portion, a semiconductor layer over the potential barrier layer suffers all damage due to the recess etching so as to permit the electron barrier to be free from any damage due to the recess etching. This also permits the electron barrier layer to be sufficiently thin to be free from any possibility of a generation of a lattice mismatching.

[0040] A first embodiment according to the present invention will hereinafter be described with reference to FIG. 2 in which a novel high frequency and high speed field effect transistor having an improved Schottky gate structure is provided. A structure of the field effect transistor is illustrated in FIG. 2. The transistor has a semi-insulating InP substrate 1. An undoped InAlAs buffer layer 2-1 having a thickness of 300 nanometers is formed on the undoped semi-insulating InP substrate 1. An undoped InGaAs channel layer 2-2 having a thickness of 30 nanometers is formed on the undoped InAlAs buffer layer 2-1. An undoped InAlAs layer 2-3 having a thickness of 3 nanometers is formed on the undoped InGaAs channel layer 2-2. A Si-doped InAlAs layer 2-4 having a thickness of 10 nanometers and an impurity concentration of 5X10^{18} cm^{-3} is formed on the undoped InAlAs layer 2-3. An undoped InAlAs layer 3 having a thickness of 20 nanometers is formed on the Si-doped InAlAs layer 2-4. A first electron barrier layer 4-1 made of an undoped AlAs having a thickness of 5 nanometers is formed on the undoped InAlAs layer 3. An undoped InAlAs layer 5 having a thickness of 5 nanometers is formed on the first electron barrier layer 4-1. A second electron barrier layer 4-2 made of an undoped AlAs having a thickness of 5 nanometers is formed on the undoped InAlAs layer 5. An undoped InAlAs layer 6 having a thickness of 10 nanometers is formed on the second electron barrier layer 4-2. A recess etched cap layer made of a Si-doped InGaAs compound semiconductor having an impurity concentration of 6 X 10^{18} cm^{-3} constituting drain and source regions 7-1 and 7-2. Drain and source electrodes 8-1 and 8-2 are provided on the Si-doped InGaAs drain and source regions 7-1 and 7-2. The drain and source electrodes 8-1 and 8-2 may be formed by evaporations of AuGe and Ni and subsequent alloy process therefor. A Schottky gate electrode 9 is provided on an exposed surface of the undoped InAlAs layer 6 in a recess portion.

[0041] The channel layer 2-2 made of the undoped InGaAs compound semiconductors has a lowest conduction band edge to provide a higher electron mobility which permits the field effect transistor to exhibit high frequency and high speed performances. The undoped InGaAs channel layer 2-2 has such a very thin as to permit electrons serving as carriers to be confined to form a two dimensional electron gas in the undoped InGaAs channel layer 2-2. The thickness of the undoped InGaAs channel layer 2-2 is variable. Much more thin undoped InGaAs channel layer having a thickness of 10 nanometers is available in which the number of electrons confined in the channel layer 2-2 is reduced, while the electron have a high energy in the average. The above undoped InGaAs channel layer having a very small thickness and a very high electron mobility permits the field effect transistor to possess high frequency and high speed performances. The Si-doped InGaAs drain and source regions 7-1 and 7-2 have a high impurity concentration of 6 X 10^{18} cm^{-3} to form an ohmic contact with the drain and source electrodes 8-1 and 8-2 respectively. The impurity concentration of the drain and source regions may be variable to place the interface with the metal electrode in condition for a formation of ohmic contact which contributes improvements in high frequency and high speed performance of the field effect transistor.

[0042] The above field effect transistor in this embodiment has an ideal Schottky barrier structure constituting a dual potential barrier having a sufficient height to prevent electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode 9 into the InAlAs layers or the undoped InGaAs channel layer 2-2. The Schottky barrier structure has dual potential barriers comprising the first and second undoped AlAs electron barrier layers 4-1 and 4-2. The first and second dual undoped AlAs electron barrier layers 4-1 and 4-2 are provided at an adjacent portion to the Schottky contact surface to ensure a prevention of electrons acting as carriers to move across the Schottky contact surface from the Schottky gate electrode 9 into the InAlAs layers and the channel layer 2-2. Each of the undoped AlAs electron barrier layers 4-1 and 4-2 has a very small thickness of 5 nanometers which is less than a critical thickness to avoid any appearance of crystal dislocation due to a lattice mismatching between AlAs and InAlAs. The above undoped AlAs electron barrier layers 4-1 and 4-2 are free from any problem with appearance of the crystal dislocation. On the other hand, each of the undoped AlAs electron barrier layers 4-1 and 4-2 has a sufficient height of the conduction band edge
or a sufficient potential barrier height to permit a considerable low probability of tunneling of electrons through each of the electron barrier layers 4-1 and 4-2. Namely, such a sufficient height of the potential barrier or the conduction band edge of the individual AlAs electron barrier layers 4-1 and 4-2 is able to prevent electrons acting as carriers from the Schottky gate electrode to pass through the barrier layer. The energy band gap profile across the Schottky barrier structure is represented in FIG. 12. The dotted line labeled by E_F represents a Fermi level. The real line labeled by E_C represents a conduction band edge profile across the Schottky contact. The Schottky barrier structure has dual potential barrier heights having different heights. An InAlAs layer in contact with the Schottky gate electrode constitutes a first electron barrier, while an AlAs layer in contact with the InAlAs layer constitutes a second electron barrier having a larger height than that of the first electron barrier layer. The height of the first potential barrier caused by the InAlAs layer is not so sufficient to ensure a prevention of electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode. By contrast, the height of the second potential barrier of the AlAs electron barrier layer is sufficient to prevent that electrons flow across the Schottky contact surface from the Schottky gate electrode and then pass through the second potential barrier. The conduction band edge discontinuity between the first InAlAs layer and the AlAs electron barrier layer permits the prevention of the electrons to pass through the Schottky barrier. This prevents a gate leakage current in which the majority carriers would be electrons.

[0044] As modifications, the electron barrier layers 4-1 and 4-2 may be made by other compound semiconductor materials having a sufficient potential barrier height. It was confirmed that GaAs, GaP, AlP, In_0.2Al_0.8As (0<X<0.4), Al_xGa_xAs (0<X<1), Al_yGa_1-yAs (0<X<1), GaAs_xP_y (0<Y<1), AlAs_xP_y (0<Y<1), Al_xGa_xAs_yP_y (0<X<1, 0<Y<1), Al_xIn_yAs_yP_y (0<X<1, 0<Y<1, 0.4<X+y<2) are available for the electron barrier layers 4-1 and 4-2.

[0045] A second embodiment according to the present invention will hereinafter be described with reference to FIG. 3 in which a novel high frequency and high speed field effect transistor having an improved Schottky gate structure is provided. A structure of the field effect transistor is illustrated in FIG. 3. The transistor has a semi-insulating InP substrate 11. An undoped InAlAs buffer layer 12-1 having a thickness of 300 nanometers is formed on the undoped semi-insulating InP substrate 11. A Si-doped InGaAs channel layer 12-2 having a thickness of 10 nanometers and an impurity concentration of 2 x 10^16 cm^-3 is formed on the undoped InAlAs buffer layer 12-1. An undoped InAlAs layer 13 having a thickness of 20 nanometers is formed on the Si-doped InGaAs layer 12-2. A first electron barrier layer 14-1 made of undoped AlAs having a thickness of 5 nanometers is formed on the undoped InAlAs layer 13. An undoped InAlAs layer 15 having a thickness of 5 nanometers is formed on the first electron barrier layer 14-1. A second electron barrier layer 14-2 made of undoped AlAs having a thickness of 5 nanometers is formed on the undoped InAlAs layer 15. An undoped InAlAs layer 16 having a thickness of 10 nanometers is formed on the second electron barrier layer 14-2. A recess etched cap layer made of a Si-doped InGaAs compound semiconductor having an impurity concentration of 6 x 10^18 cm^-3 constituting drain and source regions 17-1 and 17-2. Drain and source electrodes 18-1 and 18-2 are provided on the Si-doped InGaAs drain and source regions 17-1 and 17-2. The drain and source electrodes 18-1 and 18-2 may be formed by evaporation of AuGe and Ni and subsequent alloy process therefor. A Schottky gate electrode 19 is provided on an exposed surface of the undoped InAlAs layer 16 in a recess portion.

[0046] The channel layer 12-2 made of the Si-doped InGaAs compound semiconductors has a lowest conduction band edge to provide a higher electron mobility which permits the field effect transistor to exhibit high frequency and high speed performances. The Si-doped InGaAs channel layer 12-2 has such a very thin as to permit electrons serving as carriers to be confined to form a two dimensional electron gas in the Si-doped In-
GaAs channel layer 12-2. The Si-doped InGaAs channel layer having a very small thickness and a very high electron mobility permits the field effect transistor to possess high high performance.

[0047] The Si-doped InGaAs drain and source regions 17-1 and 17-2 have a high impurity concentration of 6 X 10^{18} cm^{-3} to form an ohmic contact with the drain and source electrodes 18-1 and 18-2 respectively. The impurity concentration of the drain and source regions may be variable to place the interface with the metal electrode in condition for a formation of ohmic contact which contributes improvements in high frequency and high speed performance of the field effect transistor.

[0048] The above field effect transistor in this embodiment has an ideal Schottky barrier structure constituting dual potential barriers having a sufficient height to prevent electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode 19 into the InAlAs layers or the Si-doped InGaAs channel layer 12-2. The Schottky barrier structure has dual potential barriers comprising the first and second undoped AlAs electron barrier layers 14-1 and 14-2. The first and second dual undoped AlAs electron barrier layers 14-1 and 14-2 are provided at an adjacent portion to the Schottky contact surface to ensure a prevention of electrons acting as carriers to move across the Schottky contact surface from the Schottky gate electrode 19 into the InAlAs layers and the channel layer 12-2. Each of the undoped AlAs electron barrier layers 14-1 and 14-2 has a very small thickness of 5 nanometers which is less than a critical thickness to avoid any appearance of crystal dislocation due to a lattice mismatching between AlAs and InAlAs. The above Si-doped AlAs electron barrier layers 14-1 and 14-2 are free from any problem with appearance of the crystal dislocation. On the other hand, each of the undoped AlAs electron barrier layers 14-1 and 14-2 has a sufficient height of the conduction band edge or a sufficient potential barrier height to permit a considerable low probability of tunneling of electrons through each of the electron barrier layers 14-1 and 14-2. Namely, such a sufficient height of the potential barrier or the conduction band edge of the individual AlAs electron barrier layers 14-1 and 14-2 is able to prevent electrons acting as carriers from the Schottky gate electrode to pass through the barrier layer.

[0049] The above dual electron barrier layers 14-1 and 14-2 are provided not to be exposed in the recess portion or not directly to contact with the Schottky gate electrode. The second electron barrier layer 14-2 overlying the first electron barrier layer 14-1 is covered by the undoped InAlAs layer 16. The undoped InAlAs layer 16 is provided only to protect the second AlAs electron barrier layer 14-2 from suffering any damage due to the recess etching process to form the recess portion in which the Schottky gate electrode 19 is provided. Although it is preferable to provide the dual electron barrier layers 14-1 and 14-2 in the vicinity of the Schottky contact surface, the InAlAs layer 16 is necessary to protect the electron barrier layers 14-1 and 14-2 from any impact due to the recess etching process. The thickness of the InAlAs layer 16 should be sufficient to achieve a perfect protection of the second electron barrier layer 14-2 from any impact due to the recess etching process. For example, in replace of 10 nanometers thickness, 5 nanometers thickness would be acceptable for that purpose. Namely, the undoped InAlAs layer 16 is to receive all impact due to the recess etching process to form the recess portion so that the undoped AlAs barrier layer 14-2 covered and protected by the undoped InAlAs layer 16 would be free from any impact due to the recess etching process. This permits the dual AlAs electron barrier layers 14-1 and 14-2 to exhibit an excellent and sufficient ability as the electron barriers to prevent electrons to flow across the Schottky barrier from the Schottky gate. This leads to no gate leakage current of the field effect transistor and a high yield of the transistor.

[0050] As modifications, the electron barrier layers 14-1 and 14-2 may be made by other compound semiconductor materials having a sufficient potential barrier height. It was confirmed that GaAs, GaP, AlP, In_xAl_{1-x}As (0<x<0.4), Al_yGa_{1-y}As (0<x<1), Al_yGa_{1-y}P (0<x<1), GaAs_{0.5-y}yP (0<y<1), Al_{0.5-y}yP (0<y<1), Al_{0.5-y}yAs_{0.5+y} (0<y<1), 0.48<x+y<2 are available for the electron barrier layers 14-1 and 14-2.

[0051] A third embodiment according to the present invention will hereinafter be described with reference to FIG. 4 in which a novel high frequency and high speed field effect transistor having an improved Schottky gate structure is provided. A structure of the field effect transistor is illustrated in FIG. 4. The transistor has a semi-insulating InP substrate 11. A Fe-doped InP buffer layer 22-1 having a thickness of 300 nanometers and an impurity concentration of 1 X 10^{15} cm^{-3} is formed on the undoped semi-insulating InP substrate 21. A Si-doped InP channel layer 22-2 having a thickness of 10 nanometers and an impurity concentration of 2 X 10^{18} cm^{-3} is formed on the Fe-doped InP buffer layer 22-1. An undoped InAlAs layer 23 having a thickness of 20 nanometers is formed on the Si-doped InP channel layer 22-2. A first electron barrier layer 24-1 made of an undoped AlAs having a thickness of 5 nanometers is formed on the undoped InAlAs layer 23. An undoped InAlAs layer 25 having a thickness of 5 nanometers is formed on the first electron barrier layer 24-1. A second electron barrier layer 24-2 made of an undoped AlAs having a thickness of 5 nanometers is formed on the undoped InAlAs layer 25. An undoped InAlAs layer 26 having a thickness of 10 nanometers is formed on the second electron barrier layer 24-2. A recess etched cap layer made of a Si-doped InGaAs compound semiconductor having an impurity concentration of 6 X 10^{16} cm^{-3} constituting drain and source regions 27-1 and 27-2. Drain and source electrodes 28-1 and 28-2 are provided on the Si-doped InGaAs drain and source regions 27-1 and 27-2. The
drain and source electrodes 25-1 and 26-2 may be formed by evaporations of AuGe and Ni and subsequent alloy process thereafter. A Schottky gate electrode 29 is provided on an exposed surface of the undoped InAlAs layer 26 in a recess portion.

[0052] The channel layer 22-2 made of the Si-doped InP compound semiconductors has a lower conduction band edge to provide a higher electron mobility which permits the field effect transistor to exhibit high frequency and high speed performances. The Si-doped InP channel layer 22-2 has such a very thin as to permit electrons serving as carriers to be confined to form a two dimensional electron gas in the Si-doped InP channel layer 22-2. The Si-doped InP channel layer having a very small thickness and a very high electron mobility permits the field effect transistor to possess high frequency and high speed performances.

[0053] The Si-doped InGaAs drain and source regions 27-1 and 27-2 have a high impurity concentration of 6 x 10^18 cm^-3 to form an ohmic contact with the drain and source electrodes 25-1 and 26-2 respectively. The impurity concentration of the drain and source regions may be variable to place the interface with the metal electrode in condition for a formation of ohmic contact which contributes improvements in high frequency and high speed performance of the field effect transistor.

[0054] The above field effect transistor in this embodiment has an ideal Schottky barrier structure constituting dual potential barrier having a sufficient height to prevent electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode 29 into the InAlAs layers or the Si-doped InGaAs channel layer 22-2. The Schottky barrier structure has dual potential barriers comprising the first and second undoped AlAs electron barrier layers 24-1 and 24-2. The first and second dual undoped AlAs electron barrier layers 24-1 and 24-2 are provided at an adjacent junction with the Schottky contact surface to ensure a prevention of electrons acting as carriers to move across the Schottky contact surface from the Schottky gate electrode 29 into the InAlAs layers and the channel layer 22-2. Each of the undoped AlAs electron barrier layers 24-1 and 24-2 has a very small thickness of 5 nanometers which is less than a critical thickness to avoid any appearance of crystal dislocation due to a lattice mismatching between AlAs and InAlAs. The above Si-doped AlAs electron barrier layers 24-1 and 24-2 are free from any problem with appearance of the crystal dislocation. On the other hand, each of the undoped AlAs electron barrier layers 24-1 and 24-2 has a sufficient height of the conduction band edge or a sufficient potential barrier height to permit a considerable low probability of tunneling of electrons through each of the electron barrier layers 24-1 and 24-2. Namely, such a sufficient height of the potential barrier or the conduction band edge of the individual AlAs electron barrier layers 24-1 and 24-2 is able to prevent electrons acting as carriers from the Schottky gate electrode to pass through the barrier layer.

[0055] The above dual electron barrier layers 24-1 and 24-2 are provided not to be exposed in the recess portion or not directly to contact with the Schottky gate electrode. The second electron barrier layer 24-2 covering the first electron barrier layer 24-1 is covered by the undoped InAlAs layer 26. The undoped InAlAs layer 26 is provided only to protect the second AlAs electron barrier layer 24-2 from suffering any damage due to the recess etching process to form the recess portion in which the Schottky gate electrode 29 is provided. Although it is preferable to provide the dual electron barrier layers 24-1 and 24-2 in the vicinity of the Schottky contact surface, the InAlAs layer 26 is necessary to protect the electron barrier layers 24-1 and 24-2 from any impact due to the recess etching process. The thickness of the InAlAs layer 26 should be sufficient to achieve a perfect protection of the second electron barrier layer 24-2 from any impact due to the recess etching process. For example, in replace of 10 nanometers thickness, 5 nanometers thickness would be acceptable for that purpose. Namely, the undoped InAlAs layer 26 is to receive all impact due to the recess etching process to form the recess portion so that the undoped AlAs barrier layer 24-2 covered and protected by the undoped InAlAs layer 26 would be free from any impact due to the recess etching process. This permits the dual AlAs electron barrier layers 24-1 and 24-2 to exhibit an excellent and sufficient ability as the electron barriers to prevent electrons to flow across the Schottky barrier from the Schottky gate. This leads to no gate leakage current of the field effect transistor and a high yield of the transistor.

[0056] As modifications, the electron barrier layers 24-1 and 24-2 may be made by other compound semiconductor materials having a sufficient potential barrier height. It was confirmed that GaAs, GaP, AlP, InAs, AlAs (0<x<0.4), In_xGa_yAs (0<x<1), Al_xGa_yAs (0<x<1), GaAs_xP_y (0<y<1), AlAs_xP_y (0<y<1), Al_xGa_yAs_xP_y (0<x<1, 0<y<1), Al_xIn_yAs_xP_y (0<x<1, 0<y<1, 0.4<x+y<2) are available for the electron barrier layers 24-1 and 24-2.

[0057] A fourth embodiment according to the present invention will hereinafter be described with reference to FIG. 2 in which a novel high frequency and high speed field effect transistor having an improved Schottky gate structure is provided. A structure of the field effect transistor is illustrated in FIG. 5. The transistor had a semi-insulating InP substrate 31. An undoped InAlAs buffer layer 32-1 having a thickness of 300 nanometers is formed on the undoped semi-insulating InP substrate 31. An undoped InGaAs channel layer 32-2 having a thickness of 30 nanometers is formed on the undoped InAlAs buffer layer 32-1. An undoped InAlAs layer 32-3 having a thickness of 3 nanometers is formed on the undoped InGaAs channel layer 32-2. A Si-doped InAlAs layer 32-4 having a thickness of 10 nanometers and an impurity concentration of 5 x 10^18 cm^-3 is formed on the undoped InAlAs layer 32-3. An undoped InAlAs layer 33
having a thickness of 20 nanometers is formed on the Si-doped InAlAs layer 32-4. An electron barrier layer 34 made of an undoped AlAs has a thickness of 5 nanometers is formed on the undoped InAlAs layer 33. An undoped InAlAs layer 38 having a thickness of 10 nanometers is formed on the electron barrier layer 34. A recess etched cap layer made of a Si-doped InGaAs compound semiconductor having an impurity concentration of 6 X 10¹⁸ cm⁻³ constituting drain and source regions 37-1 and 37-2. Drain and source electrodes 38-1 and 38-2 are provided on the Si-doped InGaAs drain and source regions 37-1 and 37-2. The drain and source electrodes 38-1 and 38-2 may be formed by evaporations of AuGe and Ni and subsequent alloy process thereof. A Schottky gate electrode 39 is provided on an exposed surface of the undoped InAlAs layer 36 in a recess portion.

[0058] From the above description, the field effect transistor in this embodiment has the same structure as that of the first embodiment except for a single electron barrier layer.

[0059] The above field effect transistor in this embodiment has an ideal Schottky barrier structure constituting a single potential barrier having a sufficient height to prevent electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode 39 into the InAlAs layers or the undoped InGaAs channel layer 32-2. The Schottky barrier structure has a single potential barrier comprising the undoped AlAs electron barrier layer 34. The single undoped AlAs electron barrier layer 34 is provided at an adjacent portion to the Schottky contact surface to ensure a prevention of electrons acting as carriers to move across the Schottky contact surface from the Schottky gate electrode 39 into the InAlAs layers and the channel layer 32-2. The undoped AlAs electron barrier layer 34 has a very small thickness of 5 nanometers which is less than a critical thickness to avoid any appearance of crystal dislocation due to a lattice mismatching between AlAs and InAlAs. The above undoped AlAs electron barrier layers 34 is free from any problem with appearance of the crystal dislocation. On the other hand, the undoped AlAs electron barrier layer 34 has a sufficient height of the conduction band edge or a sufficient potential barrier height to permit a considerable low probability of tunneling of electrons through the electron barrier layer 34. Namely, such a sufficient height of the potential barrier or the conduction band edge of the AlAs electron barrier layer 34 is able to prevent electrons acting as carriers from the Schottky gate electrode to pass through the barrier layer.

[0060] The above single electron barrier layer 34 is provided not to be exposed in the recess portion or not directly to contact with the Schottky gate electrode. The electron barrier layer 34 is covered by the undoped InAlAs layer 36. The undoped InAlAs layer 36 is provided only to protect the AlAs electron barrier layer 34 from suffering any damage due to the recess etching process to form the recess portion in which the Schottky gate electrode 39 is provided. Although it is preferable to provide the electron barrier layer 34 in the vicinity of the Schottky contact surface, the InAlAs layer 36 is necessary to protect the electron barrier layer 34 from any impact due to the recess etching process. The thickness of the InAlAs layer 36 should be sufficient to achieve a perfect protection of the electron barrier layer 34 from any impact due to the recess etching process. For example, in replace of 10 nanometers thickness, 5 nanometers thickness would be acceptable for that purpose. Namely, the undoped InAlAs layer 36 is to receive all impact due to the recess etching process to form the recess portion so that the undoped AlAs barrier layer 34 covered and protected by the undoped InAlAs layer 36 would be free from any impact due to the recess etching process. This permits the AlAs electron barrier layer 34 to exhibit an excellent and sufficient ability as the electron barriers to prevent electrons to flow across the Schottky barrier from the Schottky gate. This leads to no gate leakage current of the field effect transistor and a high yield of the transistor.

[0061] As modifications, the electron barrier layer 34 may be made by other compound semiconductor materials having a sufficient potential barrier height. It was confirmed that GaAs, GaP, AIP, In₇Al₃As (0<X<0.4), AlₓGa₁₋ₓAs (0<X<1), AlₓGa₁₋ₓP (0<X<1), GaAsₓP₁₋ₓ (0<X<1), AlₓGa₁₋ₓAs₁₋ₓP (0<X<1), 0<y<1), AlₓIn₁₋ₓAs₁₋ₓP (0<X<1), 0<y<1), 0.48<x+y<2) are available for the electron barrier layers 34.

[0062] A fifth embodiment according to the present invention will hereinafter be described with reference to FIG. 6 in which a novel high frequency and high speed field effect transistor having an improved Schottky gate structure is provided. A structure of the field effect transistor is illustrated in FIG. 6. The transistor has a semi-insulating InP substrate 41. An undoped InAlAs buffer layer 42-1 having a thickness of 300 nanometers is formed on the undoped semi-insulating InP substrate 41. A Si-doped InGaAs channel layer 42-2 having a thickness of 10 nanometers and an impurity concentration of 2 X 10¹⁸ cm⁻³ is formed on the undoped InAlAs buffer layer 42-1. An undoped InAlAs layer 43 having a thickness of 20 nanometers is formed on the Si-doped InGaAs layer 42-2. An electron barrier layer 44 made of an undoped AlAs having a thickness of 5 nanometers is formed on the undoped InAlAs layer 43. An undoped InAlAs layer 46 having a thickness of 10 nanometers is formed on the electron barrier layer 44. A recess etched cap layer made of a Si-doped InGaAs compound semiconductor having an impurity concentration of 6 X 10¹⁸ cm⁻³ constituting drain and source regions 47-1 and 47-2. Drain and source electrodes 48-1 and 48-2 are provided on the Si-doped InGaAs drain and source regions 47-1 and 47-2. The drain and source electrodes 48-1 and 48-2 may be formed by evaporations of AuGe and Ni and subsequent alloy process thereof. A
Schottky gate electrode 49 is provided on an exposed surface of the undoped InAlAs layer 46 in a recess portion.

[0063] The field effect transistor in this embodiment has the same structure as that of the second embodiment except for a single electron barrier.

[0064] The above field effect transistor in this embodiment has an ideal Schottky barrier structure consisting of a single potential barrier having a sufficient height to prevent electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode 49 into the InAlAs layers or the Si-doped InGaAs channel layer 42-2. The Schottky barrier structure has dual potential barriers comprising the undoped AlAs electron barrier layer 44. The single undoped AlAs electron barrier layer 44 is provided at an adjacent portion to the Schottky contact surface to ensure a prevention of electrons acting as carriers to move across the Schottky contact surface from the Schottky gate electrode 49 into the InAlAs layer and the channel layer 42-2. The undoped AlAs electron barrier layer 44 has a very small thickness of 5 nanometers which is less than a critical thickness to avoid any appearance of crystal dislocation due to a lattice mismatching between AlAs and InAlAs. The above undoped AlAs electron barrier layer 44 is free from any problem with appearance of the crystal dislocation. On the other hand, the undoped AlAs electron barrier layer 44 has a sufficient height of the conduction band edge or a sufficient potential barrier height to permit a considerable low probability of tunneling of electrons through the electron barrier layer 44. Namely, such a sufficient height of the potential barrier or the conduction band edge of the individual AlAs electron barrier layer 44 is able to prevent the electrons acting as carriers from the Schottky gate electrode to pass through the barrier layer.

[0065] The above single electron barrier layer 44 is provided not to be exposed in the recess portion or not directly to contact with the Schottky gate electrode. The electron barrier layer 44 is covered by the undoped InAlAs layer 46. The undoped InAlAs layer 46 is provided only to protect the AlAs electron barrier layer 44 from suffering any damage due to the recess etching process to form the recess portion in which the Schottky gate electrode 49 is provided. Although it is preferable to provide the single electron barrier layer 44 in the vicinity of the Schottky contact surface, the InAlAs layer 46 is necessary to protect the electron barrier layer 44 from any impact due to the recess etching process. The thickness of the InAlAs layer 46 should be sufficient to achieve a perfect protection of the electron barrier layer 44 from any impact due to the recess etching process. For example, in place of 10 nanometers thickness, 5 nanometers thickness would be acceptable for that purpose. Namely, the undoped InAlAs layer 46 is to receive all impact due to the recess etching process to form the recess portion so that the undoped AlAs barrier layer 44 covered and protected by the undoped InAlAs layer 46 would be free from any impact due to the recess etching process. This permits the dual AlAs electron barrier layers 44 to exhibit an excellent and sufficient ability as the electron barriers to prevent electrons to flow across the Schottky barrier from the Schottky gate. This leads to no gate leakage current of the field effect transistor and a high yield of the transistor.

[0066] As modifications, the electron barrier layer 44 may be made by other compound semiconductor materials having a sufficient potential barrier height. It was confirmed that GaAs, GaP, AlP, InP, AlGaAs (0<X<0.4), AlGaAs (0<X<1), AlGaAs (0<X<1), AlGaAs (0<X<1), AlGaAs (0<X<1), AlGaAs (0<X<1), AlGaAs (0<X<1), AlGaAs (0<X<1), AlGaAs (0<X<1), 0.48×X+Y<2) are available for the electron barrier layer 44.

[0067] A sixth embodiment according to the present invention will hereinafter be described with reference to FIG. 7 in which a novel high frequency and high speed field effect transistor having an improved Schottky gate structure is provided. A structure of the field effect transistor is illustrated in FIG. 7. The transistor has a semi-insulating InP substrate 51. A Fe-doped InP buffer layer 52-1 having a thickness of 300 nanometers and an impurity concentration of 1 X 10^{15} cm^{-3} is formed on the undoped semi-insulating InP substrate 51. A Si-doped InP channel layer 52-2 having a thickness of 10 nanometers and an impurity concentration of 2 X 10^{18} cm^{-3} is formed on the Fe-doped InP buffer layer 52-1. An undoped InAlAs layer 53 having a thickness of 20 nanometers is formed on the Si-doped InP channel layer 52-2. An electron barrier layer 54 made of an undoped AlAs having a thickness of 5 nanometers is formed on the undoped InAlAs layer 53. An undoped InAlAs layer 55 having a thickness of 10 nanometers is formed on the electron barrier layer 54. A recess etched cap layer made of a Si-doped InGaAs compound semiconductor having an impurity concentration of 6 X 10^{18} cm^{-3} constituting drain and source regions 57-1 and 57-2. Drain and source electrodes 58-1 and 58-2 are provided on the Si-doped InGaAs drain and source regions 57-1 and 57-2. The drain and source electrodes 58-1 and 58-2 may be formed by evaporations of AuGe and Ni and subsequent alloy process therefor. A Schottky gate electrode 59 is provided on an exposed surface of the undoped InAlAs layer 56 in a recess portion.

[0068] From the above description, the field effect transistor in this embodiment has the same structure as that of the second embodiment except for a single electron barrier layer.

[0069] The above field effect transistor in this embodiment has an ideal Schottky barrier structure constituting dual potential barrier having a sufficient height to prevent electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode 59 into the InAlAs layers or the Si-doped InGaAs channel layer 52-2. The Schottky barrier structure has a single potential barrier comprising the undoped AlAs
electron barrier layer 54. The undoped AlAs electron barrier layers 54 is provided at an adjacent portion to the Schottky contact surface to ensure a prevention of electrons acting as carriers to move across the Schottky contact surface from the Schottky gate electrode 59 into the InAlAs layers and the channel layer 52.2. The undoped AlAs electron barrier layer 54 has a very small thickness of 5 nanometers which is less than a critical thickness to avoid any appearance of crystal dislocation due to a lattice mismatching between AlAs and InAlAs. The above undoped AlAs electron barrier layer 54 is free from any problem with appearance of the crystal dislocation. On the other hand, the undoped AlAs electron barrier layer 54 has a sufficient height of the conduction band edge or a sufficient potential barrier height to permit a considerable low probability of tunneling of electrons through the electron barrier layers 54. Namely, such a sufficient height of the potential barrier or the conduction band edge of the individual AlAs electron barrier layers 54 is able to prevent electrons acting as carriers from the Schottky gate electrode to pass through the barrier layer.

[0070] The above single electron barrier layer 54 is provided not to be exposed in the recess portion or not directly to contact with the Schottky gate electrode. The electron barrier layer 54 is covered by the undoped InAlAs layer 56. The undoped InAlAs layer 56 is provided only to protect the AlAs electron barrier layer 54 from suffering any damage due to the recess etching process to form the recess portion in which the Schottky gate electrode 59 is provided. Although it is preferable to provide the dual electron barrier layer 54 in the vicinity of the Schottky contact surface, the InAlAs layer 56 is necessary to protect the electron barrier layers 54 from any impact due to the recess etching process. The thickness of the InAlAs layer 56 should be sufficient to achieve a perfect protection of the electron barrier layer 54 from any impact due to the recess etching process. For example, in replace of 10 nanometers thickness, 5 nanometers thickness would be acceptable for that purpose. Namely, the undoped InAlAs layer 56 is to receive all impact due to the recess etching process to form the recess portion so that the undoped AlAs barrier layer 54 covered and protected by the undoped InAlAs layer 56 would be free from any impact due to the recess etching process. This permits the dual AlAs electron barrier layer 54 to exhibit an excellent and sufficient ability as the electron barriers to prevent electrons to flow across the Schottky barrier from the Schottky gate. This leads to no gate leakage current of the field effect transistor and a high yield of the transistor.

[0071] As modifications, the electron barrier layer 54 may be made by other compound semiconductor materials having a sufficient potential barrier height. It was confirmed that GaAs, GaP, AlP, InP, AlGa1-xAs (0<x<0.4), AlxGa1-xAs (0<x<1), AlxGa1-yP (0<x<1), GaAsyP1-y (0<y<1), AlxGa1-yAsyP1-y (0<x<1, 0<y<1), AlxIn1-xAsyP1-y (0<x<1, 0<y<1), 0.48<X+Y<2 ) are available for the electron barrier layer 54.

[0072] A seventh embodiment according the present invention will hereinafter be described with reference to FIG. 8 in which a novel high frequency and high speed field effect transistor having an improved Schottky gate structure is provided. A structure of the field effect transistor is illustrated in FIG. 8. The transistor has a semi-insulating GaAs substrate 61. An undoped GaAs buffer layer 62-1 having a thickness of 400 nanometers is formed on the undoped semi-insulating GaAs substrate 61. An undoped AlGaxGa1-xAs spacer layer 62-2 having a thickness of 3 nanometers is formed on the undoped GaAs buffer layer 62-1. A Si-doped AlGaAs channel layer 62-3 having a thickness of 40 nanometers and an impurity concentration of 2 X 1018 cm-3 is formed on the undoped AlGaAs spacer layer 62-2. An undoped AlGaAs layer 63 having a thickness of 20 nanometers is formed on the Si-doped AlGaAs channel layer 62-2. A first electron barrier layer 64-1 made of an undoped AlAs having a thickness of 5 nanometers is formed on the undoped AlGaAs layer 63. An undoped AlGaAs layer having a thickness of 5 nanometers 65 is formed on the first electron barrier 64-1. A second electron barrier layer 64-2 made of an undoped AlAs having a thickness of 5 nanometers is formed on the undoped AlGaAs layer 65. An undoped AlGaAs layer 66 having a thickness of 10 nanometers is formed on the second electron barrier layer 64-2. A recess etched cap layer made of a Si-doped GaAs compound semiconductor having an impurity concentration of 6 X 1018 cm-3 constituting drain and source regions 67-1 and 67-2. Drain and source electrodes 65-1 and 68-2 are provided on the Si-doped GaAs drain and source regions 67-1 and 67-2. The drain and source electrodes 68-1 and 68-2 may be formed by evaporations of AuGe and Ni and subsequent alloy process therefor. A Schottky gate electrode 69 is provided on an exposed surface of the undoped AlGaAs layer 66 in a recess portion.

[0073] The above field effect transistor in this embodiment has an ideal Schottky barrier structure constituting dual potential barriers having a sufficient height to prevent electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode 69 into the AlGaAs layers or the undoped AlGaAs channel layer 62-3. The Schottky barrier structure has dual potential barriers comprising the undoped AlAs electron barrier layers 64-1 and 64-2. The dual undoped AlAs electron barrier layers 64-1 and 64-2 are provided at an adjacent portion to the Schottky contact surface to ensure a prevention of electrons acting as carriers to move across the Schottky contact surface from the Schottky gate electrode 69 into the AlGaAs layers and the channel layer 62-3. Each of the undoped AlAs electron barrier layers 64-1 and 64-2 has a very small thickness of 5 nanometers which is less than a critical thickness to avoid any appearance of crystal dislocation due to a lattice mismatching between AlAs and AlGaAs. The
above undoped AlAs electron barrier layers 64-1 and 64-2 are free from any problem with appearance of the crystal dislocation. On the other hand, the undoped AlAs electron barrier layers 64-1 and 64-2 have a sufficient height of the conduction band edge or a sufficient potential barrier height to permit a considerable low probability of tunneling of electrons through the electron barrier layer 64. Namely, such a sufficient height of the potential barrier or the conduction band edge of the AlAs electron barrier layers 64-1 and 64-2 is able to prevent electrons acting as carriers from the Schottky gate electrode to pass through the barrier layer.

[0074] The above dual electron barrier layer 64-1 and 64-2 are provided not to be exposed in the recess portion or not directly to contact with the Schottky gate electrode. The electron barrier layer 64 is covered by the undoped AlGaAs layer 66. The undoped AlGaAs layer 66 is provided only to protect the second AlAs electron barrier layer 64-2 from suffering any damage due to the recess etching process to form the recess portion in which the Schottky gate electrode 69 is provided. Although it is preferable to provide the electron barrier layers 64-1 and 64-2 in the vicinity of the Schottky contact surface, the AlGaAs layer 66 is necessary to protect the electron barrier layers 64-1 and 64-2 from any impact due to the recess etching process. The thickness of the AlGaAs layer 66 should be sufficient to achieve a perfect protection of the electron barrier layer 64 from any impact due to the recess etching process. For example, in replace of 10 nanometers thickness, 5 nanometers thickness would be acceptable for that purpose. Namely, the undoped AlGaAs layer 66 is to receive all impact due to the recess etching process to form the recess portion so that the second undoped AlAs barrier layer 64-2 covered and protected by the undoped AlGaAs layer 66 would be free from any impact due to the recess etching process. This permits the AlAs electron barrier layers 64-1 and 64-2 to exhibit an excellent and sufficient ability as the electron barriers to prevent electrons to flow across the Schottky barrier from the Schottky gate. This leads to no gate leakage current of the field effect transistor and a high yield of the transistor.

[0075] As modifications, the electron barrier layer 64 may be made by other compound semiconductor materials having a sufficient potential barrier height. It was confirmed that GaP, AlP, AlGaAs, AlAsP (0<x<1), GaAs, AlAs (0<y<1), AlInAs, AlInP, InAsP (0<x<1, 0<y<1), AlInAs, AlInP (0<x<1, 0<y<1, 0.48<x+y<2) are available for the electron barrier layers 64-1 and 64-2.

[0076] An eight embodiment according to the present invention will hereinafter be described with reference to FIG. 9 in which a novel high frequency and high speed field effect transistor having an improved Schottky gate structure is provided. A structure of the field effect transistor is illustrated in FIG. 9. The transistor has a semi-insulating GaAs substrate 71. An undoped GaAs buffer layer 72-1 having a thickness of 400 nanometers is formed on the undoped semi-insulating GaAs substrate 71. An undoped AlGaAs spacer layer 72-2 having a thickness of 3 nanometers is formed on the undoped GaAs buffer layer 72-1. A Si-doped AlGaAs channel layer 72-3 having a thickness of 40 nanometers and an impurity concentration of 2 x 10^{18} cm^{-3} is formed on the undoped AlGaAs spacer layer 72-2. An undoped AlGaAs layer 73 having a thickness of 20 nanometers is formed on the Si-doped AlGaAs channel layer 72-2. A single electron barrier layer 74 made of an undoped AlAs having a thickness of 5 nanometers is formed on the undoped AlGaAs layer 73. An undoped AlGaAs layer 66 having a thickness of 10 nanometers is formed on the electron barrier layer 74. A recess etched cap layer made of a Si-doped GaAs compound semiconductor having an impurity concentration of 6 x 10^{18} cm^{-3} constituting drain and source regions 77-1 and 77-2. Drain and source electrode 78-1 and 78-2 are provided on the Si-doped GaAs drain and source regions 77-1 and 77-2. The drain and source electrodes 78-1 and 78-2 may be formed by evaporations of AuGe and Ni and subsequent alloy process therefor. A Schottky gate electrode 79 is provided on an exposed surface of the undoped AlGaAs layer 76 in a recess portion.

[0077] The above field effect transistor in this embodiment has an ideal Schottky barrier structure constituting a single potential barriers having a sufficient height to prevent electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode 79 into the AlGaAs layers or the undoped AlGaAs channel layer 72-3. The Schottky barrier structure has a single potential barrier comprising the undoped AlAs electron barrier layers 74. The dual undoped AlAs electron barrier layer 74 is provided at an adjacent portion to the Schottky contact surface to ensure a prevention of electrons acting as carriers to move across the Schottky contact surface from the Schottky gate electrode 79 into the AlGaAs layer and the channel layer 72-3. The undoped AlAs electron barrier layer 74 has a very small thickness of 5 nanometers which is less than a critical thickness to avoid any appearance of crystal dislocation due to a lattice mismatching between AlAs and AlGaAs. The above undoped AlAs electron barrier layer 74 is free from any problem with appearance of the crystal dislocation. On the other hand, the undoped AlAs electron barrier layer 74 has a sufficient height of the conduction band edge or a sufficient potential barrier height to permit a considerable low probability of tunneling of electrons through the electron barrier layer 74. Namely, such a sufficient height of the potential barrier or the conduction band edge of the AlAs electron barrier layer 74 is able to prevent electrons acting as carriers from the Schottky gate electrode to pass through the barrier layer.

[0078] The above single electron barrier layer 74 is provided not to be exposed in the recess portion or not directly to contact with the Schottky gate electrode. The electron barrier layer 74 is covered by the undoped Al-
GaAs layer 76. The undoped AlGaAs layer 76 is provided only to protect the AIAs electron barrier layer 74 from suffering any damage due to the recess etching process to form the recess portion in which the Schottky gate electrode 79 is provided. Although it is preferable to provide the electron barrier layer 74 in the vicinity of the Schottky contact surface, the AlGaAs layer 76 is necessary to protect the electron barrier layer 74 from any impact due to the recess etching process. The thickness of the AlGaAs layer 76 should be sufficient to achieve a perfect protection of the electron barrier layer 74 from any impact due to the recess etching process. For example, in replace of 10 nanometers thickness, 5 nanometers thickness would be acceptable for that purpose. Namely, the undoped AlGaAs layer 76 is to receive all impact due to the recess etching process to form the recess portion so that the second undoped AIAs barrier layer 74 covered and protected by the undoped AlGaAs layer 76 would be free from any impact due to the recess etching process. This permits the AIAs electron barrier layer 74 to exhibit an excellent and sufficient ability as the electron barriers to prevent electrons to flow across the Schottky barrier from the Schottky gate. This leads to no gate leakage current of the field effect transistor and a high yield of the transistor.

[0079] As modifications, the electron barrier layer 74 may be made by other compound semiconductor materials having a sufficient potential barrier. It was confirmed that GaP, AlTe, Al_xGa_1-xP (0<x<1), GaAs_xP_1-x (0<y<1), Al_xGa_1-xP_Y (0<x<1, 0<y<1), Al_xIn_1-xAs_yP_Y (0<x<1, 0<y<1, 0.48<x+y<2) are available for the electron barrier layer 74.

[0080] A ninth embodiment according to the present invention will hereinafter be described with reference to FIG. 10 in which a novel high frequency and high speed field effect transistor having an improved Schottky gate structure is provided. A structure of the field effect transistor is illustrated in FIG. 10. The transistor has a silicon substrate 81. An undoped GaAs buffer layer 82-1 having a thickness of 800 nanometers is formed on the silicon substrate 81. An undoped AlGaAs spacer layer 82-2 having a thickness of 3 nanometers is formed on the undoped GaAs buffer layer 82-1. A Si-doped AlGaAs channel layer 82-3 having a thickness of 40 nanometers and an impurity concentration of 2x10^{18} cm^{-3} is formed on the undoped AlGaAs spacer layer 82-2. An undoped AlGaAs layer 83 having a thickness of 20 nanometers is formed on the Si-doped AlGaAs channel layer 82-2. A first electron barrier layer 84-1 made of an undoped AlGaAs having a thickness of 5 nanometers is formed on the undoped AlGaAs layer 83. An undoped AlGaAs layer 85 having a thickness of 5 nanometers is formed on the first electron barrier layer 84-1. A second electron barrier layer 84-2 made of an undoped AlGaAs having a thickness of 5 nanometers is formed on the undoped AlGaAs layer 85. An undoped AlGaAs layer 86 having a thickness of 10 nanometers is formed on the second electron barrier layer 84-2. A recess etched cap layer made of a Si-doped GaAs compound semiconductor having an impurity concentration of 6x10^{18} cm^{-3} constituting drain and source regions 87-1 and 87-2. Drain and source electrodes 88-1 and 88-2 are provided on the Si-doped GaAs drain and source regions 87-1 and 87-2. The drain and source electrodes 88-1 and 88-2 may be formed by evaporations of AuGe and Ni and subsequent alloy process therefor. A Schottky gate electrode 89 is provided on an exposed surface of the undoped AlGaAs layer 86 in a recess portion.

[0081] The above field effect transistor in this embodiment has an ideal Schottky barrier structure constituting dual potential barriers having a sufficient height to prevent electrons acting as carriers to flow across the Schottky contact surface from the Schottky gate electrode 89 into the AlGaAs layers or the undoped AlGaAs channel layer 82-3. The Schottky barrier structure has dual potential barriers comprising the undoped AIAs electron barrier layers 84-1 and 84-2. The dual undoped AIAs electron barrier layer 84-1 and 84-2 are provided at an adjacent portion to the Schottky contact surface to ensure a prevention of electrons acting as carriers to move across the Schottky contact surface from the Schottky gate electrode 89 into the AlGaAs layers and the channel layer 82-3. Each of the undoped AIAs electron barrier layers 84-1 and 84-2 has a very small thickness of 5 nanometers which is less than a critical thickness to avoid any appearance of crystal dislocation due to a lattice mismatching between AIAs and AlGaAs. The above undoped AIAs electron barrier layers 84-1 and 84-2 are free from any problem with appearance of the crystal dislocation. On the other hand, the undoped AIAs electron barrier layers 84-1 and 84-2 have a sufficient height of the conduction band edge or a sufficient potential barrier height to permit a considerable low probability of tunneling of electrons through the electron barrier layer 84. Namely, such a sufficient height of the potential barrier or the conduction band edge of the AIAs electron barrier layers 84-1 and 84-2 is able to prevent electrons acting as carriers from the Schottky gate electrode to pass through the barrier layer.

[0082] The above dual electron barrier layers 84-1 and 84-2 are provided not to be exposed in the recess portion or not directly to contact with the Schottky gate electrode. The electron barrier layer 84 is covered by the undoped AlGaAs layer 86. The undoped AlGaAs layer 86 is provided only to protect the second AIAs electron barrier layer 84-2 from suffering any damage due to the recess etching process to form the recess portion in which the Schottky gate electrode 89 is provided. Although it is preferable to provide the electron barrier layers 84-1 and 84-2 in the vicinity of the Schottky contact surface, the AlGaAs layer 86 is necessary to protect the electron barrier layers 84-1 and 84-2 from any impact due to the recess etching process. The thickness of the AlGaAs layer 86 should be sufficient to achieve a perfect protection of the electron barrier layer 84 from any im-
impact due to the recess etching process. For example, in replace of 10 nanometers thickness, 5 nanometers thickness would be acceptable for that purpose. Namely, the undoped AlGaAs layer 66 is to receive all impact due to the recess etching process to form the recess portion so that the second undoped AlAs barrier layer 84-2 covered and protected by the undoped AlGaAs layer 66 would be free from any impact due to the recess etching process. This permits the AlAs electron barrier layers 84-1 and 84-2 to exhibit an excellent and sufficient ability as the electron barriers to prevent electrons to flow across the Schottky barrier from the Schottky gate. This leads to no gate leakage current of the field effect transistor and a high yield of the transistor.

[00682] As modifications, the electron barrier layer 84 may be made by other compound semiconductor materials having a sufficient potential barrier height. It was confirmed that GaP, AlP, Al_{1-x}Ga_{1-x}P (0<x<1), GaAs, Ga_xP_y (0<y<1), AlAs, Al_xP_y (0<y<1), Al_{1-x}Ga_{1-x}As, Al_xP_y (0<x<1, 0<y<1), Al_{1-x}Ga_{1-x}As, Al_xP_y (0<x<1, 0<y<1), 0.48<2x+2y<2) are available for the electron barrier layers 84-1 and 84-2.

[00683] A tenth embodiment according to the present invention will hereinafter be described with reference to FIG. 11 in which a novel high frequency and high speed field effect transistor having an improved Schottky gate structure is provided. A structure of the field effect transistor is illustrated in FIG. 11. The transistor has a silicon substrate 91. An undoped GaAs buffer layer 92-1 having a thickness of 800 nanometers is formed on the silicon substrate 91. An undoped AlGaAs spacer layer 92-2 having a thickness of 3 nanometers is formed on the undoped GaAs buffer layer 92-1. A Si-doped AlGaAs channel layer 92-3 having a thickness of 40 nanometers and an impurity concentration of 2 X 10^{18} cm^{-3} is formed on the undoped AlGaAs spacer layer 92-2. An undoped AlGaAs layer 93 having a thickness of 20 nanometers is formed on the Si-doped AlGaAs channel layer 92-2. A single electron barrier layer 94 made of an undoped AlAs having a thickness of 5 nanometers is formed on the undoped AlGaAs layer 93. An undoped AlGaAs layer 66 having a thickness of 10 nanometers is formed on the electron barrier layer 94. A recess etched cap layer made of a Si-doped AlGaAs compound semiconductor having an impurity concentration of 6 X 10^{18} cm^{-3} constituting drain and source regions 97-1 and 97-2. Drain and source electrodes 98-1 and 98-2 are provided on the Si-doped GaAs drain and source regions 97-1 and 97-2. The drain and source electrodes 98-1 and 98-2 may be formed by evaporations of AuGe and Ni and subsequent alloy process therefor. A Schottky gate electrode 99 is provided on an exposed surface of the undoped AlGaAs layer 96 in a recess portion.

[00685] As modifications, the electron barrier layer 94 may be made by other compound semiconductor materials having a sufficient potential barrier height. It was Schottky contact surface from the Schottky gate electrode 99 into the AlGaAs layers or the undoped AlGaAs channel layer 92-3. The Schottky barrier structure has a single potential barrier comprising the undoped AlAs electron barrier layers 94. The dual undoped AlAs electron barrier layer 94 is provided at an adjacent portion to the Schottky contact surface to ensure a prevention of electrons as carriers to move across the Schottky contact surface from the Schottky gate electrode 99 into the AlGaAs layers and the channel layer 92-3. The undoped AlAs electron barrier layer 94 has a very small thickness of 5 nanometers which is less than a critical thickness to avoid any appearance of crystal dislocation due to a lattice mismatching between AlAs and AlGaAs. The above undoped AlAs electron barrier layer 94 is free from any problem with appearance of the crystal dislocation. On the other hand, the undoped AlAs electron barrier layer 94 has a sufficient height of the conduction band edge or a sufficient potential barrier height to permit a considerable low probability of tunneling of electrons through the electron barrier layer 94. Namely, such a sufficient height of the potential barrier or the conduction band edge of the AlAs electron barrier layer 94 is able to prevent electrons acting as carriers from the Schottky gate electrode to pass through the barrier layer.

[00686] The above single electron barrier layer 94 is provided not to be exposed in the recess portion or not directly to contact with the Schottky gate electrode. The electron barrier layer 94 is covered by the undoped AlGaAs layer 96. The undoped AlGaAs layer 96 is provided only to protect the AlAs electron barrier layer 94 from suffering any damage due to the recess etching process to form the recess portion in which the Schottky gate electrode 99 is provided. Although it is preferable to provide the electron barrier layer 94 in the vicinity of the Schottky contact surface, the AlGaAs layer 96 is necessary to protect the electron barrier layer 94 from any impact due to the recess etching process. The thickness of the AlGaAs layer 96 should be sufficient to achieve a perfect protection of the electron barrier layer 94 from any impact due to the recess etching process. For example, in replace of 10 nanometers thickness, 5 nanometers thickness would be acceptable for that purpose. Namely, the undoped AlGaAs layer 96 is to receive all impact due to the recess etching process to form the recess portion so that the second undoped AlAs barrier layer 94 covered and protected by the undoped AlGaAs layer 96 would be free from any impact due to the recess etching process. This permits the AlAs electron barrier layer 94 to exhibit an excellent and sufficient ability as the electron barriers to prevent electrons to flow across the Schottky barrier from the Schottky gate. This leads to no gate leakage current of the field effect transistor and a high yield of the transistor.
confirmed that GaP, AlP, AlxGa1-xP (0<X<1), GaAs1-yP1-y (0<Y<1), AlAs1-yP1-y (0<Y<1), AlxGa1-xAs1-yP1-y (0<X<1, 0<Y<1, 0.48 < X+Y <2) are available for the electron barrier layer 94.

Claims

1. A Schottky barrier structure having a Schottky gate electrode (39), wherein said Schottky barrier structure comprises:

a first layer (6; 16; 26; 36; 46; 56; 66; 76; 86; 96) in contact with said Schottky gate electrode (39), said first layer being made of a first compound semiconductor being undoped, and said first layer having a thickness in the range of 5 to 10 nanometers;

a second layer (4-1.4-2; 14-2.14-1; 24-2.24-1; 34; 44; 54; 64-2.64-1; 74; 84-2.84-1; 94) in contact with said first layer (36), said second layer (34) being made of a second compound semiconductor being undoped and having a higher conduction band edge than a conduction band edge of said first compound semiconductor, said second layer having a thickness of 5 nanometers;

a third layer (3; 13; 23; 33; 43; 53; 63; 73; 83; 93) in contact with said second layer (34), said third layer (33) being made of a third compound semiconductor being undoped and having a smaller conduction band edge than a conduction band edge of said second compound semiconductor, said third layer having a thickness of 20 nanometers; and

a fourth layer (2-4.2-3.2-2.2-1; 12-2.12.1; 22-2.22-1; 32; 42-2.42-1; 52-2.52-1; 62-3; 62-2.62-1; 72-3.72-2.72-1; 82-3.82-2.82-1; 92-3.92-2.92-1) in contact with said third layer, said fourth layer being made of a fourth compound semiconductor being doped with an impurity.

2. The Schottky barrier structure as claimed in claim 1, characterized in that said first compound semiconductor comprises a compound semiconductor including In.

3. The Schottky barrier structure as claimed in claim 2, characterized in that said first compound semiconductor comprises InAlAs.

4. The Schottky barrier structure as claimed in claim 1, characterized in that said second compound semiconductor comprises AlAs.

5. The Schottky barrier structure as claimed in claim 1, characterized in that said second compound semiconductor comprises GaP.

6. The Schottky barrier structure as claimed in claim 1, characterized in that said second compound semiconductor comprises AlAs.

7. The Schottky barrier structure as claimed in claim 1, characterized in that said second compound semiconductor comprises InxAl1-xAs (0<X<0.4).

8. The Schottky barrier structure as claimed in claim 1, characterized in that said second compound semiconductor comprises AlxGa1-xAs (0<x<1).

9. The Schottky barrier structure as claimed in claim 1, characterized in that said second compound semiconductor comprising said AlxGa1-xAs (0<x<1).

10. The Schottky barrier structure as claimed in claim 1, characterized in that said second compound semiconductor comprising GaAs1-yP1-y (0<Y<1).

11. The Schottky barrier structure as claimed in claim 1, characterized in that said second compound semiconductor comprising AlAs1-yP1-y (0<Y<1).

12. The Schottky barrier structure as claimed in claim 1, characterized in that said second compound semiconductor comprising AlxGa1-xAs1-yP1-y (0<X<1, 0<Y<1).

13. The Schottky barrier structure as claimed in claim 1, characterized in that said second compound semiconductor comprising AlxIn1-xAs1-yP1-y (0<X<1, 0<Y<1, 0.48 < X+Y <2).

14. A Schottky barrier structure according to claim 1, characterized in that the fourth layer (4-1) has a thickness of 5 nanometers.

15. A Schottky gate field effect transistor comprising:

a semiconductor substrate (1);

a fifth layer (2-2) formed on said semiconductor substrate and said fifth layer being made of a fifth compound semiconductor;

a sixth layer (2-3, 2-4, 3) formed on said fifth layer and said sixth layer being made of a sixth compound semiconductor having a higher conduction band edge than a conduction band edge of said fifth compound semiconductor the sixth layer comprising a third layer (3) being
made of a third compound semiconductor being undoped and having a thickness of 20 nanometers, the sixth layer further comprising a fourth layer (2-4) in contact with said third layer, said fourth layer being made of a fourth compound semiconductor being doped with an impurity;

a second layer (4-1, 5, 4-2) formed on said sixth layer and in contact with said third layer and having a larger conduction band edge than the conductor band edge of the third layer and said second layer including at least one electron barrier layer made of a second compound semiconductor having a higher conduction band edge than said conduction band edge of said sixth compound semiconductor said second layer being undoped and having a thickness of 5 nanometers;

a first layer (6) being undoped formed on and in contact with said second layer and said first layer being made of a first compound semiconductor having a lower condition band edge than said conduction band edge of said second compound semiconductor and having a thickness in the range of 5-10 nanometers;

source and drain regions (7-1, 7-2) separated through a recess portion from one another and formed on said first layer and said source and drain regions being made of a seventh compound semiconductor having a lower conduction band edge than said conduction band edge of said first compound semiconductor;

source and drain electrodes (8-1, 8-2) provided on said source and drain regions; and

a Schottky gate electrode (9) provided on an exposed surface of said first layer in said recess portion.

16. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second layer comprises dual electron barrier layers (4-1, 4-2) sandwiching a seventh layer (5) made of a seventh compound semiconductor having a higher conduction band edge than said conduction band edge of said second compound semiconductor.

17. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said first compound semiconductor comprises a compound semiconductor including In.

18. The Schottky gate field effect transistor as claimed in claim 17, characterized in that said first compound semiconductor comprises In-AlAs.

19. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said first compound semiconductor comprises a compound semiconductor including GaAs.

20. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second compound semiconductor comprises AlAs.

21. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second compound semiconductor comprises GaAs.

22. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second compound semiconductor comprises GaP.

23. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second compound semiconductor comprises In$_x$Al$_{1-x}$As (0< x< 0.4).

24. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second compound semiconductor comprises Al$_x$Ga$_{1-x}$As (0< x< 1).

25. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second compound semiconductor comprises Al$_x$Ga$_{1-x}$P (0< x< 1).

26. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second compound semiconductor comprises GaAs$_x$P$_{1-x}$ (0< x< 1).

27. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second compound semiconductor comprises AlAs$_x$P$_{1-x}$ (0< x< 1).

28. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second compound semiconductor comprise Al$_x$Ga$_{1-x}$As$_y$P$_{1-y}$ (0< x< 1, 0< y< 1).

29. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said second compound semiconductor comprises Al$_x$In$_{1-x}$As$_y$P$_{1-y}$ (0< x< 1, 0< y< 1, 0.48< x+ y< 2).

30. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said electron barrier layer has a thickness of 5 nanometers.
31. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said semiconductor substrate is made of a semi-insulating InP.

32. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said semiconductor substrate is made of a semi-insulating GaAs.

33. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said semiconductor substrate is made of silicon.

34. The Schottky gate field effect transistor as claimed in claim 16, characterized in that said seventh layer is made of InAlAs.

35. The Schottky gate field effect transistor as claimed in claim 16, characterized in that said seventh layer is made of AlGaAs.

36. The Schottky gate field effect transistor as claimed in claim 16, characterized in that said seventh layer has a thickness of 5 nanometers.

37. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said sixth layer comprises:

an undoped InAlAs layer having a thickness of 3 nanometers formed on said fifth layer;

a Si-doped InAlAs layer having a thickness of 10 nanometers formed on said undoped InAlAs layer; and

an undoped InAlAs layer having a thickness of 20 nanometers formed on said Si-doped InAlAs layer.

38. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said sixth layer comprises an undoped AlGaAs layer having a thickness of 20 nanometers formed on said fifth layer.

39. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said source and drain regions are made of a Si-doped InGaAs having an impurity concentration of $6 \times 10^{18}$ cm$^{-3}$.

40. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said source and drain regions are made of an n-doped GaAs having an impurity concentration of $5 \times 10^{18}$ cm$^{-3}$.

41. The Schottky gate field effect transistor as claimed in claim 15, further comprising an undoped InAlAs buffer layer having a thickness of 300 nanometers formed between said semiconductor substrate and said fifth layer.

42. The Schottky gate field effect transistor as claimed in claim 15, further comprising an undoped GaAs buffer layer having a thickness in the range of from 400 nanometers to 800 nanometers formed between said semiconductor substrate and said fifth layer.

43. The Schottky gate field effect transistor claimed in claim 42, further comprising an undoped Al$_{0.2}$Ga$_{0.8}$As spacer layer having a thickness of 3 nanometers formed between said buffer layer and said fifth layer.

44. The Schottky gate field effect transistor claimed in claim 15, characterized in that said fifth layer comprises a Si-doped InGaAs having an impurity concentration of $2 \times 10^{18}$ cm$^{-3}$.

45. The Schottky gate field effect transistor as claimed in claim 15, characterized in that said fifth layer comprises a Si-doped AlGaAs having an impurity concentration of $2 \times 10^{18}$ cm$^{-3}$.

Patentansprüche

1. Ein Schottky-Barrierenaufbau mit einer Schottky-Torelektrode (39), dadurch gekennzeichnet, daß der Schottky-Barrierenaufbau folgendes aufweist:

   eine erste Schicht (6; 16; 26; 36; 46; 56; 66; 76; 86; 96), die die Schottky-Torelektrode (39) be-rührt, wobei die erste Schicht aus einem ersten Verbindungshalbleiter hergestellt ist, der undo-tiert ist, und die erste Schicht eine Dicke im Be-reich von 5 bis 10 Nanometer aufweist;

   eine zweite Schicht (4-1,4-2; 14-2,14-1; 24-2,24-1; 34; 44; 54; 64-2,64-1; 74; 84-2,84-1; 94), die die erste Schicht (36) berührt, wobei die zweite Schicht (34) aus einem zweiten Verbindungshalbleiter hergestellt ist, der undotiert ist und eine höhere Leitungsbandkante auf-weist als eine Leitungsbandkante des ersten Verbindungshalbleiters, wobei die zweite Schicht eine Dicke von 5 Nanometer aufweist;

   eine dritte Schicht (3; 13; 23; 33; 43; 53; 63; 73; 83; 93), die die zweite Schicht (34) berührt, wobei die dritte Schicht (33) aus einem dritten Verbindungshalbleiter hergestellt ist, der undotiert ist und eine niedrigere Leitungsbandkante auf-weist als eine Leitungsbandkante des zweiten Verbindungshalbleiters, wobei die dritte Schicht eine Dicke von 20 Nanometer aufweist;
eine vierte Schicht (2-4, 2-3, 2-2, 2-1; 12-2, 12-1; 22-2, 22-1; 32; 42-2, 42-1; 52-2, 52-1; 62-3, 62-2, 62-1; 72-3, 72-2, 72-1; 82-3, 82-2, 82-1; 92-2, 92-2, 92-1), die dritte Schicht berührt, wobei die vierte Schicht aus einem vierten Verbindungshalbleiter hergestellt ist, der mit einer Verunreinigung dotiert ist.

2. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß der erste Verbindungshalbleiter einen Verbindungshalbleiter mit In aufweist.

3. Schottky-BARRIERENAUFBAU nach Anspruch 2, dadurch gekennzeichnet, daß der erste Verbindungshalbleiter InAlAs aufweist.

4. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter AlAs aufweist.

5. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter GaAs aufweist.

7. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter InAs, InAlAs (0 < X < 0.4) aufweist.

8. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter AlGa, As (0 < X < 1) aufweist.

9. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter AlGa, As (0 < X < 1) aufweist.

10. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter GaAs, P (0 < Y < 1) aufweist.

11. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter AlAs, P (0 < Y < 1) aufweist.

12. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter AlGa, As (0 < X < 1, 0 < Y < 1) aufweist.

13. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter AlGa, InAs (0 < X < 1, 0 < Y < 1, 0.48 < X+Y < 2) aufweist.

14. Schottky-BARRIERENAUFBAU nach Anspruch 1, dadurch gekennzeichnet, daß die vierte Schicht (4-1) eine Dicke von 5 Nanometer aufweist.

15. Ein Schottky-Tor-FELDEFFEKTTRANSISTOR, der folgendermaßen aufweist:

- ein Halbleitersubstrat (1);
- eine fünfte Schicht (2-2), die auf dem Halbleitersubstrat ausgebildet ist, und wobei die fünfte Schicht aus einem fünften Verbindungshalbleiter hergestellt ist;
- eine sechste Schicht (2-3, 2-4, 3), die auf der fünften Schicht ausgebildet ist, und wobei die sechste Schicht aus einem sechsten Verbindungshalbleiter hergestellt ist, der eine höhere Leitungsbandkante aufweist als eine Leitungsbandkante des fünften Verbindungshalbleiters, wobei die sechste Schicht eine dritte Schicht (3) aufweist, die aus einem dritten Verbindungshalbleiter hergestellt ist, der undotiert ist und eine Dicke von 20 Nanometer aufweist, wobei die sechste Schicht weiterhin eine vierte Schicht (2-4) aufweist, die die dritte Schicht berührt, wobei die vierte Schicht aus einem vierten Verbindungshalbleiter hergestellt ist, der mit einer Verunreinigung dotiert ist;
- eine zweite Schicht (4-1, 5, 4-2), die auf der sechsten Schicht ausgebildet ist und die dritte Schicht berührt und eine größere Leitungsbandkante aufweist als die Leitungsbandkante der dritten Schicht, und wobei die zweite Schicht mindestens eine Elektronen-Sperrschicht aufweist, die aus einem zweiten Verbindungshalbleiter hergestellt ist, der eine höhere Leitungsbandkante aufweist als die Leitungsbandkante des sechsten Verbindungshalbleiters, wobei die zweite Schicht undotiert ist und eine Dicke von 5 Nanometer aufweist;
- eine erste Schicht (6), die undotiert und auf der zweiten Schicht ausgebildet ist und diese berührt, und wobei die erste Schicht aus einem ersten Verbindungshalbleiter hergestellt ist, der eine niedrigere Leitungsbandkante aufweist als die Leitungsbandkante des zweiten Verbindungshalbleiters und eine Dicke im Bereich von 5-10 Nanometer aufweist;

Source- und Drainbereiche (7-1, 7-2), die durch einen Ausnehmungsabschnitt voneinander getrennt und auf der ersten Schicht ausgebildet sind, und wobei die Source- und Drainbereiche aus einem siebten Verbindungshalbleiter hergestellt sind, der eine niedrigere Leitungsband-
kante aufweist als die Leitungsbandkante des ersten Verbindungshalbleiters.

Source- und Drain-Elektroden (8-1, 8-2), die auf den Source- und Drainbereichen vorgesehen sind; und

eine Schottky-Tor-Elektrode (9), die auf einer freiliegenden Oberfläche der ersten Schicht im Ausnehmungsabschnitt vorgesehen ist.

16. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die zweite Schicht doppelte Elektronen-Sperrschichten (4-1, 4-2) aufweist, zwischen denen eine siebte Schicht (5) angeordnet ist, die aus einem siebten Verbindungshalbleiter hergestellt ist, der eine höhere Leitungsbandkante aufweist als die Leitungsbandkante des zweiten Verbindungshalbleiters.

17. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß der erste Verbindungshalbleiter einen Verbindungshalbleiter mit In aufweist.

18. Schottky-Tor-Feldeffekttransistor nach Anspruch 17, dadurch gekennzeichnet, daß der erste Verbindungshalbleiter InAlAs aufweist.

19. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß der erste Verbindungshalbleiter einen Verbindungshalbleiter mit GaAs aufweist.

20. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter AlAs aufweist.

21. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die zweite Schicht aus InAlAs hergestellt ist.

22. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die zweite Schicht aus InAlAs hergestellt ist.

23. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die zweite Verbindungshalbleiter In\(_x\)Al\(_{1-x}\)As (0 < X < 0,4) aufweist.

24. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die zweite Verbindungshalbleiter Al\(_x\)Ga\(_{1-x}\)As (0 < X < 1) aufweist.

25. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die zweite Verbindungshalbleiter Al\(_x\)Ga\(_{1-x}\)P (0 < X < 1) aufweist.

26. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter GaAs\(_y\)P\(_{1-y}\) (0 < Y < 1) aufweist.

27. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter AlAs\(_y\)P\(_{1-y}\) (0 < Y < 1) aufweist.

28. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß der zweite Verbindungshalbleiter Al\(_x\)In\(_{1-x}\)As\(_y\)P\(_{1-y}\) (0 < X < 1, 0 < Y < 1) aufweist.

29. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die Elektronen-Sperrschicht eine Dicke von 5 Nanometer aufweist.

30. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß das Halbleiter-Silizium aus einem halbohohlenden InP hergestellt ist.

31. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß das Halbleiter-Substrat aus Silizium hergestellt ist.

32. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß das Halbleiter-Substrat aus Silizium hergestellt ist.

33. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß das Halbleiter-Substrat aus Silizium hergestellt ist.

34. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die siebte Schicht aus InAlAs hergestellt ist.

35. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die siebte Schicht aus AlGaAs hergestellt ist.

36. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die siebte Schicht aus AlGaAs hergestellt ist.

37. Schottky-Tor-Feldeffekttransistor nach Anspruch 15, dadurch gekennzeichnet, daß die sechste Schicht folgendes aufweist:

   eine undotierte InAlAs-Schicht mit einer Dicke von 3 Nanometer, die auf der fünften Schicht ausgebildet ist;

   eine Si-dotierte InAlAs-Schicht mit einer Dicke von 10 Nanometer, die auf der undotierten In-
38. Schottky-Tor-Feldefektranzistor nach Anspruch 15, dadurch gekennzeichnet, daß die sechste Schicht eine undotierte InAlAs-Schicht mit einer Dicke von 20 Nanometer aufweist, die auf der fünften Schicht ausgebildet ist.

39. Schottky-Tor-Feldefektranzistor nach Anspruch 15, dadurch gekennzeichnet, daß die Source- und Drainbereiche aus einem Si-dotierten InGaAs mit einer Verunreinigungskonzentration von $6 \times 10^{18}$ cm$^{-3}$ hergestellt sind.

40. Schottky-Tor-Feldefektranzistor nach Anspruch 15, dadurch gekennzeichnet, daß die Source- und Drainbereiche aus einem n-dotierten GaAs mit einer Verunreinigungskonzentration von $5 \times 10^{18}$ cm$^{-3}$ hergestellt sind.

41. Schottky-Tor-Feldefektranzistor nach Anspruch 15, dadurch gekennzeichnet, daß dieser weiterhin eine undotierte InAlAs-Pufferschicht mit einer Dicke von 300 Nanometer aufweist, die zwischen dem Halbleitersubstrat und der fünften Schicht ausgebildet ist.

42. Schottky-Tor-Feldefektranzistor nach Anspruch 15, dadurch gekennzeichnet, daß dieser weiterhin eine undotierte GaAs-Pufferschicht mit einer Dicke im Bereich von 400 Nanometer bis 800 Nanometer aufweist, die zwischen dem Halbleitersubstrat und der fünften Schicht ausgebildet ist.

43. Schottky-Tor-Feldefektranzistor nach Anspruch 42, dadurch gekennzeichnet, daß dieser weiterhin eine undotierte $\text{Al}_x\text{Ga}_y\text{As}$-Abstandsschicht mit einer Dicke von 3 Nanometer aufweist, die zwischen der Pufferschicht und der fünften Schicht ausgebildet ist.

44. Schottky-Tor-Feldefektranzistor nach Anspruch 15, dadurch gekennzeichnet, daß die fünfte Schicht ein Si-dotiertes InGaAs mit einer Verunreinigungskonzentration von $2 \times 10^{18}$ cm$^{-3}$ aufweist.

45. Schottky-Tor-Feldefektranzistor nach Anspruch 15, dadurch gekennzeichnet, daß die fünfte Schicht ein Si-dotiertes AlGaAs mit einer Verunreinigungskonzentration von $2 \times 10^{18}$ cm$^{-3}$ aufweist.

Revendications

1. Structure à barrière Schottky comportant une électrode à grille Schottky (39), dans laquelle ladite structure à barrière Schottky comprend :

   une première couche (6; 16; 26; 36; 46; 56; 66; 76; 66; 96) en contact avec ladite électrode à grille Schottky (39), ladite première couche étant composée d’un premier semi-conducteur composite qui est non dopé, et ladite première couche ayant une épaisseur située dans une plage de 5 à 10 nanomètres;

   une seconde couche (4-1, 4-2, 14-2, 14-1; 24-2, 24-1; 34; 44; 54; 64-2, 64-1; 74; 84-2, 84-1; 94) en contact avec ladite première couche (36), ladite seconde couche (34) étant composée d’un second semi-conducteur composite qui est non dopé et ayant une limite de bande de conduction plus élevée que qu’une limite de bande de conduction dudit premier semi-conducteur composite, ladite seconde couche ayant une épaisseur de 5 nanomètres; une troisième couche (3; 13; 23; 33; 43; 53; 63; 73; 83; 93) en contact avec ladite seconde couche (34), ladite troisième couche (33) étant composée d’un troisième semi-conducteur composite qui est non dopé et qui a une limite de bande de conduction plus petite qu’une limite de bande de conduction dudit second semi-conducteur composite, ladite troisième couche ayant une épaisseur de 5 nanomètres; et une quatrième couche (2-4; 2-3; 2-2; 2-1; 12-2, 12-1; 22-2, 22-1; 32; 42-2, 42-1; 52-2, 52-1; 62-3, 62-2, 62-1; 72-3, 72-2, 72-1; 82-3, 82-2, 82-1; 92-3, 92-2, 92-1) en contact avec ladite troisième couche, ladite quatrième couche étant composée d’un quatrième semi-conducteur composite qui est dopé par une impureté.

2. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que ledit premier semi-conducteur composite se compose d’un semi-conducteur composite comprenant In.

3. Structure à barrière Schottky selon la revendication 2, caractérisée en ce que ledit premier semi-conducteur composite comprend de InAlAs.

4. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que ledit second semi-conducteur composite comprend AlAs.

5. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que ledit second semi-conducteur composite comprend GaAs.

6. Structure à barrière Schottky selon la revendication
1. caractérisée en ce que ledit second semi-conducteur composite comprend GaP.

7. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que ledit second semi-conducteur composite comprend In₃Al₃₋ₓAs (0 < x < 0,4).

8. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que ledit second semi-conducteur composite comprend AlₓGa₁₋ₓAs (0 < x < 1).

9. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que ledit second semi-conducteur composite comprend AlₓGa₁₋ₓAsP (0 < x < 1).

10. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que ledit second semi-conducteur composite comprend GaAsyPy (0 < y < 1).

11. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que ledit second semi-conducteur composite comprend Al₂₆₁₋ₓAs₁ₓPy (0 < x < 1; 0 < y < 1).

12. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que ledit second semi-conducteur composite comprend AlₓGa₁₋ₓAs₁₋ₓPy (0 < x < 1; 0 < y < 1; 0,48 < x + y < 2).

13. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que ledit second semi-conducteur composite comprend AlₓIn₁₋ₓAs₁₋ₓPy (0 < x < 1; 0 < y < 1; 0,48 < x + y < 2).

14. Structure à barrière Schottky selon la revendication 1, caractérisée en ce que la quatrième couche (4 - 1) a une épaisseur de 5 nanomètres.

15. Transistor à effet de champ à grille Schottky comprenant :

   un substrat semi-conducteur (1);
   une cinquième couche (2 - 2) formée sur ledit substrat semi-conducteur et ladite cinquième couche se composant d’un cinquième semi-conducteur composite;
   une sixième couche (2-3, 2-4, 3) formée sur ladite cinquième couche et ladite sixième couche étant composée d’un sixième semi-conducteur composite ayant une limite de bande de conduction plus élevée qu’une limite de bande de conduction dudit cinquième semi-conducteur composite, la sixième couche comprenant une troisième couche (3) composée d’un troisième semi-conducteur composite qui est non dopé et ayant une épaisseur de 20 nanomètres, la sixième couche comprenant en outre une quatrième couche (2-4) en contact avec ladite troisième couche. ladite quatrième couche étant composée d’un quatrième semi-conducteur composite qui est dopé par une impureté;
   une seconde couche (4-1, 5, 4-2) formée sur ladite sixième couche et en contact avec ladite troisième couche et ayant une limite de bande de conduction plus élevée que la limite de bande de conduction de la troisième couche, et ladite seconde couche comprenant au moins une couche barrière d’électrons se composant d’un second semi-conducteur composite ayant une limite de bande de conduction plus élevée que ladite limite de bande de conduction dudit sixième semi-conducteur composite, ladite seconde couche étant non dopée et ayant une épaisseur de 5 nanomètres;
   une première couche (6) qui est non dopée formée sur ladite seconde couche et en contact avec celle-ci et ladite première couche étant composée d’un premier semi-conducteur composite ayant une limite de bande de conduction plus faible que ladite limite de bande de conduction dudit second semi-conducteur composite et ayant une épaisseur située dans une plage de 5 à 10 nanomètres;
   des zones de source et de drain (7-1, 7-2) séparées l’une de l’autre par une partie en retrait et formées sur ladite première couche et lesdites zones de source et de drain étant composées d’un septième semi-conducteur composite ayant une limite de bande de conduction moins élevée que ladite limite de bande de conduction dudit premier semi-conducteur composite;
   des électrodes de source et de drain (8-1, 8-2) disposées sur lesdites zones de source et de drain; et
   une électrode de grille Schottky (9) disposée sur une surface apparente de ladite première couche dans ladite partie en retrait.

16. Transistor à effet de champ à grille Schottky selon la revendication 15, caractérisé en ce que ladite seconde couche comprend des couches barrière d’électrons doubles (4-1, 4-2) prenant en sandwich une septième couche (5) composée d’un septième semi-conducteur composite ayant une limite de bande de conduction plus élevée que ladite limite de bande de conduction dudit second semi-conducteur composite.

17. Transistor à effet de champ à grille Schottky selon la revendication 15, caractérisé en ce que ledit premier semi-conducteur composite comprend un semi-conducteur composite qui inclut In.
18. Transistor à effet de champ à grille Schottky selon le revendication 17, caractérisé en ce que ladit premier semi-conducteur composite comprend InAlAs.

19. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit premier semi-conducteur composite comprend un semi-conducteur composite qui inclut GaAs.

20. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit second semi-conducteur composite comprend AlAlAs.

21. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit second semi-conducteur composite comprend GaAs.

22. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit second semi-conducteur composite comprend GaP.

23. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit second semi-conducteur composite comprend InAlAs (0 < x < 0,4).

24. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit second semi-conducteur composite comprend AlGaAs (0 < X < 1).

25. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit second semi-conducteur composite comprend AlGaP (0 < X < 1).

26. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit second semi-conducteur composite comprend GaAs (0 < y < 1).

27. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit second semi-conducteur composite comprend AlAs (0 < y < 1).

28. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit second semi-conducteur composite comprend AlGaAs (0 < x < 1, 0 < y < 1).

29. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit second semi-conducteur composite comprend InAlAs (0 < x < 1, 0 < y < 1, 0,48 < x + y < 2).

30. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladite couche barrière d'électrons a une épaisseur de 5 nanomètres.

31. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit substrat semi-conducteur se compose d'un semi-isolant en InP.

32. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit substrat semi-conducteur est composé en un semi-isolant en GaAs.

33. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladit substrat semi-conducteur est composé de silicium.

34. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladite septième couche est composée de InAlAs.

35. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladite septième couche a une épaisseur de 5 nanomètres.

36. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladite septième couche a une épaisseur de 5 nanomètres.

37. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladite sixième couche comprend une couche en InAlAs non dopée ayant une épaisseur de 3 nanomètres et formée sur ladite cinquième couche.

38. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladite sixième couche comprend une couche en InAlAs dopée au silicium ayant une épaisseur de 10 nanomètres formée sur ladite couche en InAlAs non dopée.

39. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladites zones de source et de drain sont composées de InGaAs dopé au silicium ayant une concentration d'impuretés de 6 x 10¹⁸ cm⁻³.

40. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladites
zones de source et de drain sont composées de GaAs dopé n ayant une concentration d'impuretés de 5 x 10^{18} cm^{-3}.

41. Transistor à effet de champ à grille Schottky selon le revendication 15, comprenant en outre une couche tampon non dopée en InAlAs ayant une épaisseur de 300 nanomètres formée entre celui substrat semi-conducteur et ladite cinquième couche.

42. Transistor à effet de champ à grille Schottky selon le revendication 15, comprenant en outre une couche tampon non dopée en GaAs ayant une épaisseur située dans une plage de 400 nanomètres à 800 nanomètres formée entre celui substrat semi-conducteur et ladite cinquième couche.

43. Transistor à effet de champ à grille Schottky selon le revendication 42, comprenant en outre une couche de séparation non dopée en Al_{0.2} Ga_{0.8} As ayant une épaisseur de 3 nanomètres formée entre ladite couche tampon et ladite cinquième couche.

44. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladite cinquième couche comprend InGaAs dopé au silicium ayant une concentration d'impuretés de 2 x 10^{18} cm^{-3}.

45. Transistor à effet de champ à grille Schottky selon le revendication 15, caractérisé en ce que ladite cinquième couche comprend AlGaAs dopé au silicium ayant une concentration d'impuretés de 2 x 10^{18} cm^{-3}.
