Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

[0001] The present invention relates to techniques for uniformly cooling a plurality of battery units mounted on an electric vehicle.

[0002] The applicant of the present patent application proposed a battery carrying structure previously in EP-A-539 269 with the features of the preamble of claim 1. In this previously proposed battery carrying structure, a fan sucks fresh air through the interior of a battery case to cool battery units contained in the battery case.

[0003] Since the battery case is formed in an airtight construction to protect the battery units from mud and water, and the battery unit generates heat when the same is charged, the interior of the battery case needs forced cooling.

[0004] The battery case contains a plurality of battery units. Branch ducts leading from the hollow frame to the respective battery units have no different cross-sectional areas. Therefore, the battery units nearer to the fan and those farther from the fan are cooled in different degrees, and the battery carrying structure is unable to cool the plurality of battery units uniformly.

[0005] Accordingly, it is an object of the present invention to provide a technique capable of uniformly cooling battery units.

[0006] With the foregoing object in view, the present invention provides a battery unit cooling system in an electric vehicle, comprising a longitudinal, hollow frame included in the electric vehicle, wherein the frame is the longitudinal main frame of the electric vehicle; a plurality of branch ducts branching from the frame and connected respectively to a plurality of battery units arranged along the frame; a cooling fan connected to one end of the frame to cool the plurality of battery units in a forced-draft mode or an induced-draft mode; and sealing members arranged between the branch ducts and the respective battery units, characterized in that the flow passage area of the branch duct nearest to the other end of the frame is smaller than those of the other branch ducts, wherein the flow passage area of the branch ducts at positions further downstream with respect to the direction of flow of air through the frame are smaller than those of the branch ducts at positions further upstream with respect to the direction of flow of air, wherein the different flow passage areas are defined by orifices of said sealing members, said orifices having different cross-sectional areas for determining the flow rates to the respective battery units.

[0007] The branch duct farthest from the cooling fan has a flow passage area smaller than those of the other branch ducts using different cross-sectional areas in the sealing members to equalize the flow rates of air in all the branch ducts.

[0008] A battery unit cooling system in a preferred embodiment according to the present invention will be described hereinafter with reference to the accompanying drawings.

Fig. 1 is a side view of an electric vehicle incorporating a battery unit cooling system in accordance with the present invention.

Fig. 2 is a plan view of a chassis frame and the associated parts included in the electric vehicle of Fig. 1.

Fig. 3 is a cross-sectional view of the body of the electric vehicle of Fig. 1.

Fig. 4 is an exploded perspective view of a chassis frame, a battery case and the associated parts included in the electric vehicle of Fig. 1.

Fig. 5 is an exploded perspective view of controllers, a rear fender and other parts included in the electric vehicle of Fig. 1.

Fig. 6 is a side view of the electric vehicle of Fig. 1 as equipped with fenders and covers.

Fig. 7 is an exploded perspective view of fenders and covers for covering the front portion of the electric vehicle of Fig. 1.

Fig. 8 is an exploded perspective view of fenders and covers for covering the rear portion of the electric vehicle of Fig. 1.

Fig. 9 is an enlarged view of the components of the electric vehicle of Fig. 1, arranged behind the seat (a locking mechanism for locking the seat and a lid covering a plug container).

Fig. 10 is a view taken along the arrow 10 in Fig. 9.

Fig. 11 is a side view of a main frame included in the electric vehicle of Fig. 1, employed in the present invention.

Fig. 12 is a sectional view taken on line 12-12 in Fig. 11 showing first sealing members and battery units.

Fig. 13 is a sectional view taken on line 13-13 in Fig. 11, showing second sealing members and battery units.

Fig. 14 is a front view of a battery unit related with the present invention.

Fig. 15 is a plan view of a battery unit related with the present invention.

[0009] Fig. 1 is a side view of an electric vehicle incorporating a battery unit cooling system of the present invention. An electric vehicle 1, which is what is called
an electric motorcycle, comprises: a chassis frame 2 comprising a main frame 3, a head pipe 4 attached to the front end of the main frame 3, and a rear frame 5 extending obliquely upward from the rear end of the main frame 3; a front fork 7 supported on the head pipe 4; a front wheel 8 supported on the lower end of the front fork 7; a handlebar 9 attached to the upper end of the front fork 7; a battery case 10 suspended from the main frame 3; a swing power unit 14 including a driving motor 15 and pivotally joined at its front end to the rear end of the main frame 3 with a pivot shaft 13; a storage box 16 mounted on the rear frame 5; a seat 17 mounted on the rear frame 5; a rear shock absorber 18 having an upper end pivotally joined to the rear frame 5 and a lower end pivotally joined to the rear end of the swing power unit 14; and a rear wheel 21 supported on a rear axle 19 supported on the rear end of the swing power unit 14.

[0010] Electric parts including a battery charger are arranged along the rear frame 5. The chassis frame 2 is covered entirely with a cowling and fenders, which will be described later. A seat locking mechanism serving also as a locking mechanism for locking a lid covering the mouth of a plug container is disposed behind the seat 17, which will be described later.

[0011] In Fig. 1, indicated at 22 is a side stand, at 23 is a roller, at 14a is a recess for receiving the roller 23 therein, and at 24 is a license plate holder.

[0012] Fig. 2 is a plan view of the chassis frame of the electric vehicle incorporating the battery unit cooling system of the present invention. The rear frame 5 has a substantially oval shape in a plan view. A down regulator 27, a charging controller 28 for controlling battery charging operation, a motor controller 29 for controlling the driving motor and the associated parts for traveling, a battery cooling fan 30, and a fuse box 31 are arranged in that order on the rear frame 5 from the rear side toward the front side. Electric components are connected to a wiring harness 32.

[0013] The main frame 3 is a hollow pipe capable of serving as a main duct. One end of the main frame 3 is connected to a discharge duct 33 connected to the battery cooling fan 30. The construction of the main frame 3 serving also as a main duct will be described later.

[0014] In this embodiment, six battery units 35 are held on the main frame 3; three battery units 35 are arranged longitudinally on the right-hand side of the main frame 3 and three battery units 35 are arranged longitudinally on the left-hand side of the main frame 3. The battery units 35 are held in place with a battery fastening bands 36.

[0015] Fig. 3 is a cross sectional view of the chassis frame taken in the substantially middle portion of the chassis frame. The bottom plate 38 of the battery case 10 is disposed under the main frame 3, the battery units 35 are mounted on the bottom plate 38. Each battery unit 35 has an air inlet connected to a branch duct 40 branching from the main frame 3. The bottom plate 38 is formed by bending a corrugated plate and has a comparatively high rigidity. The lower ends of the battery fastening bands 36 are joined to knuckles 39 formed on the right and left side of the bottom plate 38.

[0016] Fig. 4 is an exploded perspective view of the chassis frame, the battery case and the components of the electric vehicle 1. A bridge bracket 41, a cross pipe 43 provided with a bracket 42 to which the upper end of the rear shock absorber 18 is joined pivotally, and a cross panel 45 provided with holes 44 for receiving screws for fastening the battery cooling fan are extended across and attach to the oval rear frame 5. The cross panel 45 is extended between brackets 12 for supporting the pivot shaft 13.

[0017] Indicated at 46 and 47 are lugs for supporting the charging controller 28 and the motor controller 29.

[0018] Substantially triangular brackets 49, 50 and 51 are suspended from the main frame 3, and the lower sides of the brackets 49, 50 and 51 are joined to the bottom plate 38. A long hinge pin 52 is inserted in knuckles 39 formed on each side of the bottom plate 38 and the knuckles formed at the lower ends of the battery fastening bands 36 to join the battery fastening bands 36 pivotally to the bottom plate 38.

[0019] Lower side covers 54 are attached to the opposite sides of the battery case 10, and a front cover 55 is attached to the front end of the battery case 10. In Fig. 4, indicated at 56 is a main switch including an ignition switch, at 57 are battery support plates, and at 58 and 59 are cushion members for preventing the lateral dislocation of the battery units 35.

[0020] Fig. 5 is an exploded perspective view of a portion of the electric vehicle 1 around the controllers and the rear fender. A front controller support plate 61 is fastened to the lugs 46 (Fig. 4) with bolts, and a rear controller support plate 62 is fastened to the lugs 47 (Fig. 4) with bolts.

[0021] The front controller support plate 61 is provided on its upper surface with a bracket 63 to which the battery cooling fan is attached. The front end of the charging controller 28 is fastened to the front controller support plate 61 with bolts 64. The front controller support plate 61 is provided with legs 61a at its opposite ends, and the motor controller 29 is fastened to the extremities of the legs 61a with bolts 65.

[0022] The rear end of the charging controller 28 is fastened to the rear controller support plate 62 with bolts 66. The rear controller support plate 62 is provided with legs 62a at its opposite ends, and the rear end of a rear fender 69 is fastened to the legs 62a with bolts 67. The rear fender 69 extends over a rear wheel 21, not shown in Fig. 5, and serves also as a box for containing the charging controller 28 and the motor controller 29 and the associated parts.

[0023] The internal components of the charging controller 28 generate heat during battery charging operation. Therefore, the charging controller 28 must be cooled by forced cooling. The charging controller 28 is
provided with a charger cooling fan 71 and suction hole 72 is formed in the side wall of the charging controller 28 for forced cooling.

[0024] A charging cable 73 provided with a plug 74 is stored in a charging cable box 76 formed of a resin by blow molding and provided with lugs 76a and 76b fastened to the chassis frame 2.

[0025] Heat generated within the battery charger is discharged through a discharge hose 77 shown in the lower left-hand corner of Fig. 5. A rear mud guard 78 is attached to a bracket 79.

[0026] Fig. 6 is a side view of the electric vehicle equipped with fenders and covers, Fig. 8 is an exploded perspective view of fenders and covers for covering the front portion of the chassis frame, and Fig. 8 is an exploded perspective view of fenders and covers covering the rear portion of the chassis frame.

[0027] Shown in Fig. 7 are a front fender 80, a front inner upper cover 81, a front upper cover 82 joined to the upper end of the front fender 80, a front mud guard 83 joined to the lower end of the front fender 80, a handlebar cover 84, a front inner upper cover 85, a step board 86, and side floors 87. These covering members are assembled so as to cover the main frame 3 and the head pipe 4 as shown in Fig. 6.

[0028] Referring to Fig. 8, the storage box 16 is surrounded by a main cover 90 and a central cover 91. Shown in Fig. 8 are a fuse box lid 92 put on the center cover 91 to close a fuse box so as to be removed from the center cover 91 when changing fuses, a first lid 93 and a second lid 94 covering a charging cable box, a rack 95, side covers 96 suspended from the step board 86 so as to cover the lower side openings of the battery case 10, and side covers 97 joined to the rear part of the lower edge of the main cover 90. These covering members are assembled so as to cover the main frame 3 and the rear frame 5 as shown in Fig. 6.

[0029] Parts indicated by broken lines in Fig. 6 are those previously described with reference to Fig. 1 and hence the description thereof will be omitted.

[0030] Fig. 9 is an enlarged side view of the components of a seat locking mechanism serving also as a lid locking mechanism for locking a lid covering the charging cable box arranged behind the seat of the electric vehicle incorporating the battery cooling system of the present invention. A bent locking bar (or a bent locking pipe) 101 is attached to the rear part of the lower surface of the seat 17 covering the upper open end of the storage box 16, and a seat switch 102 is disposed under the locking bar 101 and is attached to a switch support plate 103 fastened to the bridge bracket 41 with bolts.

[0031] The switch support plate 103 will be described later in detail.

[0032] The cable box is covered with a first lid 93 and a second lid 94. When taking out the charging cable 73 (Fig. 1) from the cable box, first the seat 17 is raised, the first lid 93 is opened, and then the second lid 94 is opened. The plug connected to the charging cable 73 is held by a plug holder 105.

[0033] A locking lever 107 is connected to a key cylinder 106. When the key cylinder 106 is turned so as to turn the locking lever 107 upward, the seat 17 is released.

[0034] Fig. 10 is a view taken along the arrow 10 in Fig. 9. Referring to Fig. 10, the switch support plate 103 is provided with a guide groove 108 for guiding the locking bar 101 in its upper portion, and two slots 109 and 110 having the shape of an arc of a circle formed respectively near the opposite ends of its lower portion.

[0035] The seat switch 102 is fastened to a small bracket 112 with a bolt 111, and the small bracket 112 is welded to the front surface of the switch support plate 103 so that the seat switch 102 is disposed in the center of the lower portion of the switch support plate 103.

[0036] A first swing plate 114, which is turned downward to actuate the seat switch 102 when the locking bar 101 is lowered, is supported pivotally on the switch support plate 103.

[0037] A second swing plate 116 is supported pivotally on the switch support plate 103.

[0038] The first swing plate 114 is biased counterclockwise with a spring 117, and the second swing plate is biased clockwise by the spring 117.

[0039] When the passenger leaves the seat 17, the first swing plate 114 is turned slightly counterclockwise from the position shown in Fig. 10 by the spring 117, as far as its arm 118 comes into contact with a cam 119 formed on the second swing plate 116.

[0040] Since the second swing plate 116 is stationary, the first swing plate 114 is unable to turn further counterclockwise and, consequently, the locking bar 101 is restrained from further upward movement by the first swing plate 114 and hence the seat 17 is locked in place and cannot be turned upward.

[0041] The state shown in Fig. 10 is established and first swing plate 114 depresses the seat switch 102 when the passenger sits on the seat 17. The first swing plate 114 is turned slightly counterclockwise from the position shown in Fig. 10 by the spring 117 and is separated from the seat switch 102 when the passenger is not seated on the seat 17. Thus, it is possible to detect electrically whether or not the passenger is seated on the seat 17, while the seat 17 is locked in place.

[0042] A procedure for raising the seat 17 will be described hereinafter.

[0043] The key cylinder 106 (Fig. 9) is turned to turn the locking lever 107 upward. Consequently, the second swing plate 116 (Fig. 10) is turned counterclockwise and the cam 119 of the second swing plate 116 moves below the arm 118 of the first swing plate 114 to release the arm 118. Then, the first swing plate 114 is turned counterclockwise through a large angle by the spring 117 to enable the locking bar 101 to move upward, so that the seat 17 can be raised by hand.

[0044] Fig. 11 is a side view of the main frame 3 capable of serving as a main duct. Three branch ducts 40 are
connected to the right side of the main frame 3 at positions #1, #2 and #3, and three branch ducts 40 are connected to the left side of the main frame 3 at positions #1, #2 and #3. The branching fixture 121 of each branch duct 40 is provided with drain grooves 121a so that paint will not stay within the branching fixture 121 in a painting process to be carried out after welding the branching fixtures 121 to the main frame 3.

In Fig. 11, indicated at 3a and 3b are partition plates projecting downward from the main frame 3 to separate the battery units 35 arranged on the right side of the electric vehicle and the battery units 35 arranged on the left side of the same from each other as shown in Fig. 12.

Fig. 12 is a sectional view taken on line 12-12 in Fig. 11. Referring to Fig. 12, a first sealing member 122 is attached to each of the branching fixtures 121 at the position #1. The sealing member 122 has an inner cylindrical wall 124 defining an orifice 123 having a diameter D1, and an outer cylindrical wall 125 concentric with the inner cylindrical wall 124 and closely fitted in an opening 3c formed in the main frame 3. The bell mouth of the first sealing member 122 is pressed firmly against the battery unit 35 so as to surround an air inlet 35a formed in the battery unit 35.

Since the inner cylindrical wall 124 and the outer cylindrical wall 125 of the sealing member 122 are separated by an annular space, the diameter D1 of the orifice 123 defined by the inner cylindrical wall 124 remains unchanged even if the outer cylindrical wall 125 is deformed elastically.

Although the branching fixture 121 is provided with the drain grooves 121a, the drain grooves 121a are closed by the outer cylindrical wall 125 of the sealing member 122 as shown in Fig. 12, so that air is unable to flow outside from the main frame 3 through the drain grooves 121a.

As shown in Fig. 12, the free end of each battery fastening band 36 is indicated by alternate long and two short dashes lines is fixed to the branching fixture 121 with a bolt screwed in a nut 125 fixed to the branching fixture 121, and the lower edges of the partition plates 3a separating the battery units 35 are sandwiched by cushion members 58.

Fig. 13 is a sectional view taken on line 13-13 in Fig. 11. Referring to Fig. 13, a second sealing member 127 is attached to each of the branching fixtures 121 at the position #2 or #3. The bell mouth of the second sealing member 127 is pressed firmly against the battery unit 35 so as to surround the air inlet 35a. Each second sealing member 127 has an orifice 128 having a diameter D2.

Part of air supplied through the main frame 3 leaks outside through the drain grooves 121a and the rest flows through the orifice 128 having the diameter D2 into the battery unit 35.

The function of the structure shown in Figs. 11 to 13 will be described hereinafter.

Cooling air blown by the battery cooling fan 30 (Fig. 1) flows through the main frame 3 in the direction of the arrow 1 and flows out of the main frame 3 through the branching fixtures 121. Fundamentally, the cooling air flows through the branching fixtures 121 because the front end of the main frame 3 is closed by the head pipe 4.

The flow rate of the cooling air flowing through each of the branching fixtures 121 at the position #1, i.e., the lowermost position with respect to the direction of flow of the cooling air, is greater than those of the cooling air flowing through each of the branching fixtures 121 at the positions #2 and #3, because the flow of the cooling air is stopped by the head pipe 4. Similarly, the flow rate of the cooling air flowing through the each of the branching fixtures 121 at the position #2 is slightly higher than that of the cooling air flowing through each of the branching fixtures 121 at the position #3.

As shown in Fig. 12, the orifice 123 of the first sealing member 122 determines the flow rate Q1 of the cooling air that flows through the first sealing member 122.

The diameter of the orifice of the second sealing member 127 shown in Fig. 13 is greater than that of the first sealing member 122. Therefore, the cooling air flows through the second sealing member 127 more easily than flows through the first sealing member 122. Supposing that the cooling air flows at a flow rate Q3 through the opening 3c of the main frame 3, and at Q4 through the drain grooves 121a of the branching fixture 121, the cooling air flows through the orifice 128 at a flow rate Q2 = Q3 - Q4. The respective diameters D1 and D2 of the orifices 123 and 128 are determined so that the flow rate Q2 is approximately equal to the flow rate Q1.

Fig. 14 is a front view of the battery unit 35 to be used on the electric vehicle incorporating the battery cooling system of the present invention. The battery unit 35 comprises a plurality of batteries 35b, and a battery container 35c containing the batteries 35b. A groove 35d is formed in the upper wall of the battery container 35c, and cables 131 and 132 connected respectively to the positive terminal and the negative terminal of the battery container 35c are extended in the groove 35d.

Fig. 15 is a plan view of the battery unit 35. The longer cable 131 is extended under a cover 133 having an L-shaped cross section, and the shorter cable 132 is extended outside the cover 133 and along a guide rib 134.

The battery unit 35 is mounted on the electric vehicle with the left side thereof, as viewed in Fig. 14, on the side of the main frame. When mounting the battery unit 35 on the electric vehicle, the hand 135 is put on the battery unit 35 as indicated by imaginary lines in Fig. 15. Since the cables 131 and 132 do not move toward the hand 135, the battery unit 35 can easily be mounted on the electric vehicle. If the battery unit 35 is not provided
with the guide rib 134, the cable 132 may droop and obstruct the battery unit mounting work.

[0060] In the battery cooling system of the present invention shown in Fig. 11, the respective diameters of the orifices of the sealing members at the positions #2 and #3 are equal to each other. However, the diameters of the orifices need not necessarily be equal to each other; the diameter of the orifice of the sealing member at the position #2 may be smaller than that of the orifice of the sealing member at the position #3; that is, the respective diameters of the orifices of the sealing members at the positions #1, #2 and #3 may be increased in that order, namely, the diameters of the orifices of the upper sealing members with respect to the direction of flow of the cooling air may be greater than those of the orifices of the lower sealing members.

[0061] The electric vehicle 1 that incorporates the battery cooling system of the present invention may be a motorcycle, a motor three-wheeler or a four-wheel vehicle, provided that the electric vehicle has a frame corresponding to the main frame.

[0062] Still further, the battery units may be cooled in either a forced-draft mode or an induced-draft mode.

[0063] As is apparent from the foregoing description, according to the present invention, the flow passage area of the lowest branching duct with respect to the direction of flow of cooling air is smaller than those of the other branching ducts to equalize the flow rates of cooling air flowing through the branching ducts, so that the plurality of battery units can uniformly be cooled and the plurality of battery units are able to exhibit their expected performance.

Claims

1. A battery unit cooling system in an electric vehicle (1), comprising:
   - a longitudinal, hollow frame (3) included in the electric vehicle, wherein the frame (3) is the longitudinal main frame (3) of the electric vehicle (1);
   - a plurality of branch ducts (40, 121) branching from the frame (3) and connected respectively to a plurality of battery units (35) arranged along the frame (3);
   - a cooling fan (30) connected to one end of the frame (3) to cool the plurality of battery units (35) in a forced-draft mode or an induced-draft mode; and
   - sealing members (122, 127) arranged between the branch ducts (40, 121) and the respective battery units (35), characterized in that the flow passage area (D₁) of the branch duct (40, 121) nearest to the other end of the frame (3) is smaller than those of the other branch ducts, wherein the flow passage area (D₂) of the branch ducts (40, 121) at positions further downstream with respect to the direction of flow of air through the frame (3) are smaller than those (D₂) of the branch ducts (40, 121) at positions further upstream with respect to the direction of flow of air, wherein the different flow passage areas (D₁, D₂) are defined by orifices (123, 128) of said sealing members (122, 127), said orifices (123, 128) having different cross-sectional areas for determining the flow rates (Q₁-Q₄) to the respective battery units (35).

Patentansprüche

1. Batterieeinheit-Kühlsystem in einem Elektrofahrzeug (1), umfassend:
   - einen in dem Elektrofahrzeug enthaltenen, langgestreckten, hohlen Rahmen (3), wobei der Rahmen (3) der Hauptschlusselemente (3) des Elektrofahrzeugs (1) ist;
   - eine Mehrzahl von Zweigleitungen (40, 121), die von dem Rahmen (3) abzweigen und entsprechend mit einer Mehrzahl von entlang dem Rahmen (3) angeordneten Batterieelementen (35) verbunden ist;
   - einen Kühlkörper (30), der mit einem Ende des Rahmens (3) verbunden ist, um die Mehrzahl von Batterieeinheiten (35) in einem Druckstrommodus oder einem Saugstrommodus zu kühlen; und
   - Dichtelemente (122, 127), die zwischen den Zweigleitungen (40, 121) und den jeweiligen Batterieelementen (35) angeordnet sind,
   - dadurch gekennzeichnet, daß die Durchflußfläche (D₁) der dem anderen Ende des Rahmens (3) nächsten Zweigleitung (40, 121) kleiner ist als jene der anderen Zweigleitungen, wobei die Durchflußfläche (D₂) der Zweigleitungen (40, 121) an bezüglich der Luftstromungsrichtung durch den Rahmen (3) weiteren, liegenden Stellen kleiner ist als jene (D₂) der Zweigleitungen (40, 121) an bezüglich der Luftstromungsrichtung weiteren, liegenden Stellen, wobei die unterschiedlichen Durchflußflächen (D₁, D₂) durch Öffnungen (123, 128) der Dichtelemente (122, 127) festgelegt sind, wobei die Öffnungen (123, 128) unterschiedliche Querschnittsflächen zur Bestimmung der Strömungsraten (Q₁ - Q₄) zu den jeweiligen Batterieelementen (35) aufweisen.

Revendications

1. Système de refroidissement d'accumulateurs dans un véhicule électrique (1), comprenant :
   - un châssis creux longitudinal (3) compris dans
le véhicule électrique, dans lequel le châssis (3) constitue le châssis principal longitudinal (3) du véhicule électrique (1);

- une pluralité de conduits ramifiés (40, 121) dont les ramifications partent du châssis (3) et sont connectées respectivement à une pluralité d’accumulateurs (35) agencés le long du châssis (3);

un ventilateur de refroidissement (30) relié à une extrémité du châssis (3) afin de refroidir la pluralité d’accumulateurs (35) dans un mode de tirage forcé ou dans un mode de tirage par aspiration ; et des éléments d’étanchéité (122, 127) agencés entre les conduits ramifiés (40, 121) et les accumulateurs respectifs (35), caractérisé en ce que la zone de passage d’écoulement (D1) du conduit ramifié (40, 121) la plus proche de l’autre extrémité du châssis (3) est plus petite que celles des autres conduits ramifiés, dans lesquels la zone de passage d’écoulement (D2) des conduits ramifiés (40, 121) positionnés plus en aval par rapport à la direction d’écoulement d’air à travers le châssis (3) est plus petite que celles (D2) des conduits ramifiés (40, 121) positionnés plus en amont par rapport à la direction d’écoulement d’air, dans lesquels les différentes zones de passage d’écoulement (D1, D2) sont définies par les orifices (123, 128) desdits éléments d’étanchéité (122, 127), lesdits orifices (123, 128) présentant différentes zones en coupe transversale pour déterminer les débits (Q1-Q4) pour les accumulateurs respectifs (35).
