Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

1. Field of Invention

This invention relates to introducers. More particularly, this invention relates to guiding introducers of specific shapes for use within the left atrium of the human heart.

2. Prior Art

Introducers and catheters have been in use for medical procedures for many years. For example, one use has been to convey an electrical stimulus to a selected location within the human body. Another use is to monitor and make measurements for diagnostic tests within the human body. Thus, catheters may examine, diagnose and treat while positioned at a specific location within the body which are otherwise inaccessible without more invasive procedures. In use, catheters may be inserted into a major vein or artery which is near the body surface. These catheters are then guided to the specific location for examination, diagnosis or treatment by manipulating the catheter through the artery or vein of the human body.

Catheters have become increasingly useful in remote and difficult to reach locations within the body. However, the utilization of these catheters is frequently limited because of the need for the precise placement of the tip of the catheter at a specific location within the body.

Control of the movement of catheters to achieve such precise placement is difficult because of the inherent structure of a catheter. The body of a conventional catheter is long and tubular. To provide sufficient control of the movement of the catheter, it is necessary that its structure be somewhat rigid. However, the catheter must not be so rigid as to prevent the bending or curving necessary for movement through the vein, artery or other body part to arrive at the specified location. Further, the catheter must not be so rigid as to cause damage to the artery or vein while it is being moved within the body.

While it is important that the catheter not be so rigid as to cause injury, it is also important that there be sufficient rigidity in the catheter to accommodate torque control, i.e., the ability to transmit a twisting force along the length of the catheter. Sufficient torque control enables controlled maneuverability of the catheter by the application of a twisting force at the proximal end of the catheter that is transmitted along the catheter to its distal end. The need for greater torque control often conflict with the need for reduced rigidity to prevent injury to the body vessel.

Catheters are used increasingly for medical procedures involving the human heart. In these procedures a catheter is typically advanced to the heart through veins or arteries and then is positioned at a specified location within the heart. Typically, the catheter is inserted in an artery or vein in the leg, neck, upper chest or arm of the patient and threaded, often with the aid of a guidewire or introducer, through various arteries or veins until the tip of the catheter reaches the desired location in the heart.

The distal end of a catheter used in such a procedure is sometimes preformed into a desired curvature so that by torquing the catheter about its longitudinal axis, the catheter can be manipulated to the desired location within the heart or in the arteries or veins associated with the heart. For example, U.S. Patent No. 4,882,777 discloses a catheter with a complex curvature at its distal end for use in a specific procedure in the right ventricle of a human heart. U.S. Patent No. 4,117,836 discloses a catheter for the selective coronary angiography of the left coronary artery and U.S. Patent Nos. 5,016,640 and 4,883,058 disclose catheters for selective coronary angiography of the right coronary artery. See also U.S. Patent No. 4,033,031. Finally, U.S. Patent No. 4,898,591 discusses a catheter with inner and outer layers containing braided portions.

The '591 patent also discloses a number of different curvatures for intravascular catheters.

Thus, there are a number of patents which disclose catheters with predetermined shapes, designed for use in specific medical procedures generally associated with the heart or the vascular system. Because of precise physiology of the heart and the vascular system, catheters or introducers with carefully designed shapes for predetermined uses within the human heart and vascular system are important.

Accordingly, it is an object of this invention to prepare a guiding introducer for selected medical procedures in the left atrium.

It is a further object of this invention to prepare a guiding introducer for use in selected electrophysiology procedures within the left atrium of the heart.

Another object of this invention is to prepare a guiding introducer for use in selected ablation procedures within the left atrium of the heart.

These and other objects are obtained by the design of the guiding introducers disclosed in the instant invention.

Summary of Invention

The instant invention is a guiding introducer to be used in the left atrium as defined in claims 1 and 9.

Brief Description of the Drawings

Figure 1 is a cross-section of the right side of the heart showing the right atrium and ventricle and the placement of the guiding introducer.

Figure 2 is a cross-section of the left side of the heart showing the mitral valve and the placement of the guiding introducer.

Figure 3 is a perspective view of one embodiment of the guiding introducer.

Figure 4 is a perspective view of a second embodied...
ment of the guiding introducer.

Figure 5 is a perspective view of a third embodiment of the guiding introducer.

Figure 6 is a perspective view of a fourth embodiment of the guiding introducer.

Detailed Description of the Drawings.

A typical human heart includes a right ventricle, a right atrium, left ventricle and left atrium. The right atrium is in fluid communication with the superior vena cava and the inferior vena cava. The atrioventricular septum separates the right atrium from the right ventricle. The tricuspid valve contained within the atrioventricular septum communicates the right atrium with the right ventricle. On the inner wall of the right atrium where it is connected with the left atrium is a recessed portion, the fossa ovalis. See Figures 1 and 2. In the heart of a fetus, the fossa ovalis is open, permitting the fetal blood to flow between the right and left atria. In most individuals, this opening closes after birth, but in as many as 25 percent of individuals an opening still remains in the fossa ovalis between the right and left atria. Between the fossa ovalis and the tricuspid valve is the opening or ostium for the coronary sinus. The coronary sinus is the large epicardial vein which accommodates most of the venous blood which drains from the myocardium into the right atrium.

In the normal heart, contraction and relaxation of the heart muscle (myocardium) takes place in an organized fashion as electro-chemical signals pass sequentially through the myocardium from the atrial to the ventricular tissue along a well defined route which includes the His-Purkinje system. Initial electric impulses are generated at the sinusatrial (SA) node and conducted to the atrioventricular (AV) node. The AV node lies near the ostium of the coronary sinus in the interatrial septum in the right atrium. The His-Purkinje system begins at the AV node and follows along the membranous interatrial septum toward the tricuspid valve through the atrioventricular septum and into the membranous interventricular septum. At about the middle of the interventricular septum, the His-Purkinje system splits into right and left branches which straddle the summit of the muscular part of the interventricular septum.

Sometimes abnormal rhythms occur in the heart which are referred to as arrhythmias. For example, a common arrhythmia is Wolff-Parkinson-White syndrome (W-P-W). The cause of W-P-W is the existence of an anomalous conduction pathway or pathways that connects the atria muscle tissue directly to the ventricular muscle tissue, thus by-passing the normal His-Purkinje system. These pathways are usually located in the fibrous tissue that connect the atrium and the ventricle. In recent years a technique has been developed to destroy these anomalous conduction pathways by delivering energy into the tissue in which the pathways exist. To accomplish this procedure a special electrode catheter is positioned as close as possible to the anomalous conduction pathway to maintain constant tissue contact while energy is delivered to destroy the pathway. This same type of contact with the cardiac tissue is also necessary when mapping or other procedures are employed relating to these pathways.

One end of these anomalous conduction pathways can be located either in the right atrium or in the left atrium with the other end of the pathway located in the ventricle. When the anomalous conduction pathway is located between the left atrium and the left ventricle, there are two approaches to positioning the catheter near that pathway for the appropriate medical procedure. One is to introduce the catheter into the femoral artery by a standard introducer sheath and advance it up the aorta, across the aortic valve into the left ventricle and then attempt to position its tip under the mitral valve annulus near the anomalous conduction pathway. This approach is frequently difficult for many reasons, including the difficulty in navigating the structure of the left ventricle, the fact that it requires arterial access and the potential problems associated with ablation of ventricular tissue, such as sudden cardiac death. The other approach is to introduce a transseptal sheath apparatus, a long single plane curve introducer, into the right femoral vein and advance it through the inferior vena cava into the right atrium. A puncture is then made through the fossa ovalis in the interatrial septum and the apparatus is advanced into the left atrium where the trocar and dilator of the apparatus are removed, leaving the sheath in position in the left atrium. The mapping or ablation catheter is then inserted through the sheath and into the left atrium and positioned on top of the mitral valve annulus near the anomalous conduction pathway. Specific positions may be chosen for the mapping or ablation on the left side of the heart, including specifically posteroseptal, posterior, posteriorlateral, lateral and anterolateral positions around the mitral valve annulus.

Traditionally, there have been two techniques for locating and ablating anomalous conduction pathways which are situated between the right atrium and right ventricle. Either method can be initiated by advancing a catheter through an access site into a vein in the leg, neck or upper chest.

The first technique, which approaches the pathway from the pathway's ventricular insertion site, involves entering the right atrium from either the inferior or superior vena cava, passing through the tricuspid valve, and advancing toward the apex of the right ventricle. Then the catheter is directed to make a 180 degree turn to reverse its path back up toward the right atrium and locate the accessory pathway under the tricuspid valve apparatus. The accessory pathway is then ablated from the ventricular insertion site under the tricuspid valve.

The second technique, which approaches the pathway from the atrial insertion site, is to enter the right atrium from the inferior or superior vena cava, and attempt to locate the atrial insertion site of the acces-
sory pathway around the tricuspid valve annulus. The accessory pathway is then ablated from the pathway's atrial insertion site on the atrial aspect of the tricuspid valve.

AV nodal pathways can be located and ablated from the right atrium.

Mere introduction of the catheter into the left atrium is not sufficient to effectively and efficiently perform these medical procedures, especially for the mapping or ablation of anomalous conduction pathways. These medical procedures are usually performed using a special catheter. The medical practitioners monitor the introduction of the catheter and its progress through the vascular system by a fluoroscope. Such fluoroscopes do not easily identify the specific features of the heart in general and the critically important structures of the right and left atrium in specific, thus making placement of the catheter difficult. This placement is especially difficult as the beating heart is in motion and the catheter will be moving within the right atrium and the left atrium as blood is being pumped through the heart throughout the procedure. The structure and shape of the guiding introducers of the instant invention addresses and solves these problems.

Referring now to Figures 3 through 6, the guiding introducer of the present invention for use in the left atrium is comprised of a first, second and third section. The first section is a conventional, generally elongated hollow, straight catheter section of sufficient length for introduction into the patient and for manipulation from the point of insertion to the specific desired location within the heart.

Merged with the distal end of the first section of the sheath is the second section which is curved in a compound curve, curving first upward and in a first longitudinal curve and simultaneously curving to the right in a second longitudinal curve. The first longitudinal curve has a radius of from about 0.5 cm. to about 2.0 cm. and preferably from about 0.5 cm. to about 1.5 cm. The arc of the first longitudinal curve is preferably from about 40 to about 60 degrees and most preferably from about 45 to about 55 degrees of arc. The second longitudinal curve of the second section contains a radius of from about 0.5 cm. to about 4.0 cm., preferably from about 0.5 cm. to about 3.0 cm., and most preferably from about 0.5 to about 2.0 cm. The second longitudinal curve is preferably less than about 2.0 cm. in length.

The third section of the introducer is merged with the distal end of the second section. The structure of the third section of the guiding introducer will depend on its intended use. In one embodiment (Figures 3-5) the guiding introducer is used to place a mapping or ablating catheter in a position anterior to anterolateral to lateral to posteriorlateral accessory pathways associated with the mitral valve annulus. To accomplish this, the third section is a third longitudinal curve wherein the plane of the third section is angled upward at an angle of approximately 40 to about 60 degrees, preferably 45 to about 55 degrees and, most preferably, 50 degrees from the plane of the first section and where substantially all of said third section is coplanar (at least within 15 degrees of coplanar).

To place sensing or ablating catheters at a specific location adjacent or left fibrous trigone, the arc of the third longitudinally curved section of the third section has a radius of about 35 to about 55 degrees, preferably from about 40 to about 50 degrees and, most preferably, about 45 degrees. See Figure 3.

This guiding introducer can also be used for analysis and treatment of anterolateral to lateral accessory pathways of the mitral valve annulus. For this use the third longitudinally curved section of the third section is comprised of an arc with the radius of about 80 to about 100 degrees, preferably from about 85 to about 95 degrees and, most preferably, about 90 degrees. See Figure 4.

The guiding introducer may also be used for analysis and treatment of lateral to posterolateral accessory pathways of the mitral valve annulus. In this embodiment the third longitudinally curved section is comprised of an arc with a radius of about 125 to about 145 degrees, preferably 130 to about 140 degrees and, most preferably about 135 degrees. See Figure 5.

The guiding introducer may also be used for analysis and treatment of posterolateral to posteroseptal accessory pathways of the mitral valve. A somewhat different structure is present for this embodiment because of the structure of that portion of the left atrium of the heart. (See Figure 6) While the first and second sections of this second preferred embodiment are the same as those of the first preferred embodiment, the angle of the plane of the third section in relationship to the plane of the first section is different. In this embodiment, the plane of the third section is angled upward at an angle from about 25 to about 45 degrees, preferably from about 30 to about 40 degrees, and most preferably about 35 degrees from the plane of the first section. In this embodiment the longitudinally curved section of the third section is comprised of an arc with a radius of about 170 to about 190 degrees, preferably 175 to about 185 degrees and, most preferably about 180 degrees.

The distal tip of the introducer may be, and preferably will be, tapered to form a good transition with the dilator as is the case with many introducers.

The guiding introducer may be made of any material suitable for use in humans and which has a memory or permits distortion from and subsequent substantial return to the desired three dimensional or complex multi-planar shape. For the purpose of illustration and not limitation, the internal diameter of the tip of the guiding introducer may vary from about 6 to about 10 "French" (1 French equals about 1/3 of a millimeter). Such introducer can accept dilators from about 6 to about 10 French and appropriate guidewires. Obviously, if larger or smaller dilators or catheters are used in conjunction with the guiding introducers of the instant invention, modifications in size or shape can be made to
the instant guiding introducers.

The guiding introducer preferably may contain one or a multitude of radiopaque tip marker bands near the terminus of the guiding introducer. While various modifications may be made in the shapes by increasing or decreasing its size or adding additional tip markers, it is critical to the successful location of the guiding introducer within the atrium that the shape be maintained.

The guiding introducer also preferably contains one or a plurality of vents near the distal tip of the introducer, preferably three or four of such vents. The vents are preferably located no more than about 5.0 to 6.0 cm. from the tip of the introducer and more preferably 0.5 cm. to about 4.0 cm. from the tip. The size of these vents should be in the range of about 1 to 1.5 mm (40 to 60 l/1000) of an inch in diameter. These vents are generally designed to prevent air embolisms from entering the introducer caused by the withdrawal of a catheter contained within the guiding introducer in the event the distal end of the introducer is occluded. For example, if the tip of the introducer is placed against the myocardium and the catheter located within the introducer is withdrawn a vacuum may be created within the catheter if no vents are provided. If such vacuum is formed, air may be forced back into the introducer by the reinsertion of a catheter into the lumen of the introducer. Such air embolism could cause significant problems on the patient, including the possibility of a stroke, heart attack or other such problems common with air embolisms in the heart. The addition of vents near the distal tip of the guiding introducers prevents the formation of such vacuum by permitting fluid, presumably blood, to be drawn into the lumen of the introducer as a catheter is being removed from the introducer, thus preventing the possibility of the formation of an air embolism within the introducer.

Variances in size or shape of the instant guiding introducers are also intended to encompass pediatric uses for the guiding introducer of the instant invention although the preferred uses are for adult human hearts. It is well recognized that pediatric uses may require reductions in size of the various sections of the introducer, in particular the first section, but without any significant modification to the shape or curve of the guiding introducer.

In operation, a modified Seldinger technique is normally used for the insertion of the catheter into either an artery or vein of the body. Using this procedure, a small skin incision is made at the appropriate location to facilitate the catheter or dilator passage. The subcutaneous tissue is then dissected, followed by a puncture of the vessel with an appropriate needle with stylet positioned at a relatively shallow angle. The needle is then partially withdrawn and reinserted at a slightly different angle into the vessel, making sure that the needle remains within the vessel. A soft flexible tip of an appropriate sized guidewire is then inserted through and a short distance beyond the needle into the vessel. Firmly holding the guidewire in place, the needle is removed. The wire guide is then advanced through the vessel into the inferior vena cava or into the right atrium and finally the superior vena cava. With the wire guide in place, a dilator is then placed over the wire with the guiding introducer placed over the dilator. The dilator and guiding introducer generally form an assembly to be advanced together along the guidewire into the superior vena cava. After insertion of the assembly, the guidewire is then withdrawn. A Brockenbrough or trocar needle is then inserted through the lumen of the dilator to the right atrium to be used to create an opening through the interatrial septum, preferably at the fossa ovalis. The entire assembly (dilator sheath and Brockenbrough needle) is withdrawn from the superior vena cava into the right atrium so the tip rests against the intracardial septum at the level of the fossa ovalis. The Brockenbrough needle is then advanced within the dilator to reach the fossa ovalis. After the opening is made through the interatrial septum, the needle, dilator and guiding introducer are advanced into the left atrium.

After the guiding introducer of the instant invention is advanced through the interatrial septum into the left atrium, the Brockenbrough or trocar and dilator are removed, leaving the guiding introducer in the left atrium. The catheter to be used for analysis and/or treatment of the anomalous conduction pathways is then advanced through the lumen of the guiding introducer and is placed at an appropriate location near the mitral valve annulus. The choice of the guiding introducer to be used will depend on the location of the anomalous conduction pathway, as has previously been discussed.

By choice of the desired predetermined shape of the guiding introducer in conjunction with fluoroscopic viewing, the distal portion of the guiding introducer can be manipulated to direct the distal end of a catheter placed within the lumen of the guiding introducer, to a specific internal surface with the left atrium. In addition, by providing sufficient rigidity and support as the introducer is held in place by the anatomical structure of the heart as well as the vasculature, the distal end of the guiding introducer can be maintained in that fixed location or surface position of the endocardial structure to permit the appropriate procedures to be performed. If sensing procedures are involved, the guiding introducer is placed in the desired location. At that point, the electrical activity of the heart peculiar to that location can be precisely determined by use of a sensing electrophysiology catheter placed within the guiding introducer. Further, as the guiding introducer permits precise location of catheters, an ablation catheter may be placed at a precise location for destruction by the use of energy, for example, radiofrequency, thermal, laser or direct current. This precise location of the ablation catheter tip is important as there will be no dilution of the energy delivered due to unfocused energy being dissipated over the entire cardiac chamber and lost in the circulating blood by a constantly moving tip of the ablation catheter. This permits a significantly reduced amount of energy to be
applied while still achieving efficient ablation. Further, time used to perform the procedure is significantly reduced over procedures where no guiding introducer is used.

Claims

1. A guiding introducer to be used in the left atrium of a human heart comprised of a first, second and third section wherein the first section is a generally elongated straight section, wherein merged with a distal end of said first section is the second section, wherein the second section is curved in a compound curve, curving first upward in a first longitudinal curve and simultaneously curving to the right in a second longitudinal curve wherein the second section merges with the third section, wherein said third section is a third longitudinal curve, wherein the plane of the third section is angled upward at an angle of approximately 40 to about 60 degrees from the plane of the first section, and wherein substantially all of said third section is coplanar.

2. The guiding introducer of Claim 1, wherein the second section is curved in a compound curve curving first upward in a first longitudinal curve with a radius of from about 0.5 cm to about 2.0 cm for about 40 to 60 degrees of arc, and simultaneously curving to the right in a second longitudinal curve containing a radius from about 0.5 cm to about 4.0 cm, wherein said second section is less than about 2.0 cm in length, and wherein said third section is a third longitudinally curved section with a radius of from about 1.5 cm to about 4.0 cm.

3. The guiding introducer of Claim 2 wherein the third section is an arc of the third longitudinally curved section with a radius of about 35-55 degrees.

4. The guiding introducer of Claim 2 wherein the third section is an arc of the third longitudinally curved section with a radius of about 40-45 degrees.

5. The guiding introducer of Claim 2 wherein the third section is an arc of the third longitudinally curved section with a radius of about 80-100 degrees.

6. The guiding introducer of Claim 2 wherein the third section is an arc of the third longitudinally curved section with a radius of about 85-95 degrees.

7. The guiding introducer of Claim 2 wherein the third section is an arc of the third longitudinally curved section with a radius of about 125-145 degrees.

8. The guiding introducer of Claim 2 wherein the third section is an arc of the third longitudinally curved section with a radius of about 130-140 degrees.

9. A guiding introducer to be used in the left atrium of the human heart comprised of a first, second and third section, wherein the first section is a generally elongated straight section, wherein merged with the distal end of said first section is the second section, wherein the second section is curved in a compound curve first curving upward in a first longitudinal curve and then simultaneously curving in a second longitudinal curve to the right, wherein the distal end of the second section merges with the third section which is a third longitudinal curve, wherein the plane of said third section is angled upward in an angle of about 25 to about 45 degrees from the plane of the first section, and wherein substantially all of said third section is coplanar.

10. The guiding introducer of Claim 9, wherein the second section is curved in a compound curve curving first upward in a first longitudinal curve with a radius of from about 0.5 cm to about 2.0 cm for about 40 to 60 degrees of arc, and then simultaneously curving to the right in a second longitudinal curve containing a radius from about 0.5 cm to about 4.0 cm to the right, wherein said second section is less than about 2.0 cm in length, and wherein the third section is a third longitudinally curved section with a radius of from about 1.5 cm to about 4.0 cm.

11. The guiding introducer of Claim 10 wherein the third section is an arc of the third longitudinally curved section with a radius of about 170-190 degrees.

12. The guiding introducer of any one of Claims 1, 2, 9 or 10 wherein a plurality of vents is provided near the distal tip of the introducer.

Patentansprüche

1. (Ein-)Führungsvorrichtung zur Verwendung im linken Vorhof des menschlichen Herzens, enthaltend einen ersten, einen zweiten und einen dritten Abschnitt, worin der erste Abschnitt einen allgemein langgestreckten geraden Abschnitt darstellt, worin der zweite Abschnitt mit dem distalen Ende des ersten Abschnitts verbunden ist, worin der zweite Abschnitt eine zusammengesetzte Kurve aufweist, die sich zunächst in einer ersten Längskurve nach oben krümmt und gleichzeitig in einer zweiten Längskurve nach rechts krümmt, worin der zweite Abschnitt mit dem dritten Abschnitt verbunden ist, wobei der dritte Abschnitt eine dritte Längskurve darstellt, wobei die Ebene des dritten Abschnitts in einem Winkel von etwa 40 bis 60 Grad von der Ebene des ersten Abschnitts nach oben steht, und worin im wesentlichen der gesamte dritte Abschnitt koplanar ist.

2. Die (Ein-)Führungsvorrichtung nach Anspruch 1, worin der zweite Abschnitt eine zusammengesetzte
Kurve aufweist, die sich zunächst in einer ersten Längskurve mit einem Radius von etwa 0,5 cm bis etwa 2,0 cm über etwa 40 bis 60 Winkelgrad nach oben krümmt, und sich gleichzeitig in einer zweiten Längskurve mit einem Radius von etwa 0,5 cm bis etwa 4,0 cm nach rechts krümmt, worin der zweite Abschnitt weniger als 2,0 cm lang ist, und worin der dritte Abschnitt einen dritten längskrümmten Abschnitt mit einem Radius von etwa 1,5 cm bis etwa 4,0 cm darstellt.

3. (Ein-)Führungsvorrichtung nach Anspruch 2, worin der dritte Abschnitt einen Bogen des dritten längskrümmten Abschnitts mit einem Radius von etwa 35 bis 55 Grad darstellt.

4. (Ein-)Führungsvorrichtung nach Anspruch 2, worin der dritte Abschnitt einen Bogen des dritten längskrümmten Abschnitts mit einem Radius von etwa 40 bis 45 Grad darstellt.

5. (Ein-)Führungsvorrichtung nach Anspruch 2, worin der dritte Abschnitt einen Bogen des dritten längskrümmten Abschnitts mit einem Radius von etwa 80 bis 100 Grad darstellt.

6. (Ein-)Führungsvorrichtung nach Anspruch 2, worin der dritte Abschnitt einen Bogen des dritten längskrümmten Abschnitts mit einem Radius von etwa 85 bis 95 Grad darstellt.

7. (Ein-)Führungsvorrichtung nach Anspruch 2, worin der dritte Abschnitt einen Bogen des dritten längskrümmten Abschnitts mit einem Radius von etwa 125 bis 145 Grad darstellt.

8. (Ein-)Führungsvorrichtung nach Anspruch 2, worin der dritte Abschnitt einen Bogen des dritten längskrümmten Abschnitts mit einem Radius von etwa 130 bis 140 Grad darstellt.

10. (Ein-)Führungsvorrichtung nach Anspruch 9, worin der zweite Abschnitt eine zusammengesetzte Kurve aufweist, die sich zunächst in einer ersten Längskurve mit einem Radius von etwa 0,5 cm bis etwa 2,0 cm über etwa 40 bis 60 Winkelgrad nach oben krümmt, und dann gleichzeitig in einer zweiten Längskurve mit einem Radius von etwa 0,5 cm bis etwa 4,0 cm nach rechts krümmt, worin der zweite Abschnitt weniger als 2,0 cm lang ist, und worin der dritte Abschnitt einen dritten längskrümmten Abschnitt mit einem Radius von etwa 1,5 cm bis etwa 4,0 cm darstellt.

11. (Ein-)Führungsvorrichtung nach Anspruch 10, worin der dritte Abschnitt einen Bogen des dritten längskrümmten Abschnitts mit einem Radius von etwa 170 bis 190 Grad darstellt.

12. (Ein-)Führungsvorrichtung nach einem der Ansprüche 1, 2, 9 oder 10, worin nahe der distalen Spitze der Einführungsvorrichtung mehrere Öffnungen vorgeesehen sind.

Revendications

1. Introducteur de guidage destiné à être utilisé dans l’oreillette gauche d’un coeur humain, comprenant une première, une deuxième et une troisième sections, dans lequel la première section est une section droite de forme généralement allongée, dans lequel la deuxième section est raccordée avec l’extrémité distale de ladite première section et est recourbée selon une courbe composite, tout d’abord vers le haut sous la forme d’une première courbe longitudinale et simultanément vers la droite sous la forme d’une deuxième courbe longitudinale, dans lequel la deuxième section est raccordée avec la troisième section, dans lequel ladite troisième section est une troisième courbe longitudinale, dans lequel le plan de la troisième section est plié vers le haut selon un angle d’environ 40 à 60 degrés par rapport au plan de la première section, et dans lequel ladite troisième section est sensiblement entièrement coplanaire.

2. Introducteur de guidage selon la revendication 1, dans lequel la deuxième section est recourbée selon une courbe composite tout d’abord vers le haut sous la forme d’une première courbe longitudinale d’un rayon compris entre 0,5 cm et 2,0 cm environ sur 40 à 60 degrés d’arc environ, et simultanément recourbée vers la droite sous la forme d’une deuxième courbe longitudinale contenant un rayon compris entre 0,5 cm et 4,0 cm environ, dans lequel la longueur de ladite deuxième section est inférieure à 2,0 cm, et dans lequel ladite troisième section est une troisième section recourbée longitudinalemment avec un rayon compris entre 1,5 cm et 4,0 cm environ.
3. Introducteur de guidage selon la revendication 2, dans lequel la troisième section est un arc de la troisième section recourbée longitudinalement avec un rayon d’environ 35 à 55 degrés.

4. Introducteur de guidage selon la revendication 2, dans lequel la troisième section est un arc de la troisième section recourbée longitudinalement avec un rayon d’environ 40 à 45 degrés.

5. Introducteur de guidage selon la revendication 2, dans lequel la troisième section est un arc de la troisième section recourbée longitudinalement avec un rayon d’environ 80 à 100 degrés.

6. Introducteur de guidage selon la revendication 2, dans lequel la troisième section est un arc de la troisième section recourbée longitudinalement avec un rayon d’environ 85 à 95 degrés.

7. Introducteur de guidage selon la revendication 2, dans lequel la troisième section est un arc de la troisième section recourbée longitudinalement avec un rayon d’environ 125 à 145 degrés.

8. Introducteur de guidage selon la revendication 2, dans lequel la troisième section est un arc de la troisième section recourbée longitudinalement avec un rayon d’environ 130 à 140 degrés.

9. Introducteur de guidage destiné à être utilisé dans l’oreillette gauche du cœur humain, comprenant une première, une deuxième et une troisième sections, dans lequel la première section est une section droite généralement allongée, dans lequel la deuxième section est raccordée avec l’extrémité distale de ladite première section, la deuxième section étant recourbée selon une courbe composites, tout d’abord vers le haut sous la forme d’une première courbe longitudinale et simultanément vers la droite sous la forme d’une deuxième courbe longitudinale, dans lequel l’extrémité distale de la deuxième section est raccordée avec la troisième section qui est une troisième courbe longitudinale, dans lequel le plan de ladite troisième section est plié vers le haut selon un angle d’environ 25 à 45 degrés par rapport au plan de la première section, et dans lequel ladite troisième section est sensiblement entièrement coplanaire.

10. Introducteur de guidage selon la revendication 9, dans lequel la deuxième section est recourbée selon une courbe composite tout d’abord vers le haut sous la forme d’une première courbe longitudinale d’un rayon compris entre 0,5 cm et 2,0 cm environ sur 40 à 60 degrés d’arc environ, et simultanément vers la droite sous la forme d’une deuxième courbe longitudinale contenant un rayon compris entre 0,5 cm et 4,0 cm environ vers la droite, dans lequel la longueur de ladite deuxième section est inférieure à 2,0 cm, et dans lequel ladite troisième section est une troisième section recourbée longitudinalement avec un rayon compris entre 1,5 cm et 4,0 cm environ.

11. Introducteur de guidage selon la revendication 10, dans lequel la troisième section est un arc de la troisième section recourbée longitudinalement avec un rayon d’environ 170 à 190 degrés.

12. Introducteur de guidage de l’une quelconque des revendications 1, 2, 9 ou 10, dans lequel une pluralité d’événements est prévue à proximité de l’extrémité distale de l’introducteur.
Sheath & Catheter
in
Right Atrium

1) Tricuspid Valve
2) Sheath
3) Catheter

FIG. 1
Sheath & Catheter in Left Atrium

1) Coronary Sinus
2) Mitral Valve
3) Fossa Ovalis (Patent)
4) Sheath
5) Catheter
