Description

BACKGROUND OF THE INVENTION

[0001] Growth hormone, which is secreted from the pituitary, stimulates growth of all tissues of the body that are capable of growing. In addition, growth hormone is known to have the following basic effects on the metabolic process of the body:

1. Increased rate of protein synthesis in all cells of the body;
2. Decreased rate of carbohydrate utilization in cells of the body;
3. Increased mobilization of free fatty acids and use of fatty acids for energy.

[0002] A deficiency in growth hormone secretion can result in various medical disorders, such as dwarfism.

[0003] Various ways are known to release growth hormone. For example, chemicals such as arginine, L-3,4-dihydroxyphenylalanine (L-DOPA), glucagon, vasopressin, and insulin induced hypoglycemia, as well as activities such as sleep and exercise, indirectly cause growth hormone to be released from the pituitary by acting in some fashion on the hypothalamus perhaps either to decrease somatostatin secretion or to increase the secretion of the known secretagogue growth hormone releasing factor (GRF) or an unknown endogenous growth hormone-releasing hormone or all of these.

[0004] In cases where increased levels of growth hormone were desired, the problem was generally solved by providing exogenous growth hormone or by administering an agent which stimulated growth hormone production and/or release. In either case the peptidyl nature of the compound necessitated that it be administered by injection. Initially the source of growth hormone was the extraction of the pituitary glands of cadavers. This resulted in a very expensive product and carried with it the risk that a disease associated with the source of the pituitary gland could be transmitted to the recipient of the growth hormone. Recently, recombinant growth hormone has become available which, while no longer carrying any risk of disease transmission, is still a very expensive product which must be given by injection or by a nasal spray.

[0005] Other compounds have been developed which stimulate the release of endogenous growth hormone such as analogous peptidyl compounds related to GRF or the peptides of U.S. Patent 4,411,890. These peptides, while considerably smaller than growth hormones are still susceptible to various proteases. As with most peptides, their potential for oral bioavailability is low. The instant compounds are non-peptidyl agents for promoting the release of growth hormone which may be administered parenterally, nasally or by the oral route.

[0006] European Patent Publication No. 0 513 974-A is an intervening publication relevant for the purposes of Article 54(3) and (4) EPC, which describes a related class of benzo-fused lactam derivatives that promote the release of growth hormone.

[0007] US Patent No. 4,692,522 discloses compounds which are structurally similar to those of the present invention, useful as cholecystokinin antagonists.

SUMMARY OF THE INVENTION

[0008] The instant invention covers certain benzo-fused lactam compounds which have the ability to stimulate the release of natural or endogenous growth hormone. The compounds thus have the ability to be used to treat conditions which require the stimulation of growth hormone production or secretion such as in humans with a deficiency of natural growth hormone or in animals used for food production where the stimulation of growth hormone will result in a larger, more productive animal. Thus, it is an object of the instant invention to describe the benzo-fused lactam compounds. It is a further object of this invention to describe procedures for the preparation of such compounds. A still further object is to describe the use of such compounds to increase the secretion of growth hormone in humans and animals. A still further object of this invention is to describe compositions containing the benzo-fused lactam compounds for the use of treating humans and animals so as to increase the level of growth hormone secretions. Further objects will become apparent from a reading of the following description.

The compounds of the instant invention all have at least one asymmetric center as noted by the asterisk in the structural Formula I above. Additional asymmetric centers may be present on the molecule depending upon the nature of the various substituents on the molecule. Each such asymmetric center will produce two optical isomers and it is intended that all such optical isomers, as separated, pure or partially purified optical isomers or racemic mixtures thereof, be included within the ambit of the instant invention. In the case of the asymmetric center represented by the asterisk in Formula I, it has been found that the compound in which the 3-amino substituent is above the plane of the structure, as seen in Formula Ia, is more active and thus more preferred over the compound in which the 3-amino substituent is below the plane of the structure. In the substituent \((X)_n\), when \(n = 0\), the asymmetric center is designated as the R-isomer. When \(n = 1\), this center will be designated according to the R/S rules as either R or S depending upon the value of X.

The instant compounds are generally isolated in the form of their pharmaceutically acceptable acid addition salts, such as the salts derived from using inorganic and organic acids. Examples of such acids are hydrochloric, nitric, sulfuric, phosphoric, formic, acetic, trifluoroacetic, propionic, maleic, succinic, malonic and the like. In addition, certain compounds containing an acidic function such as a carboxy can be isolated in the form of their inorganic salt in which the counterion can be selected from sodium, potassium, lithium, calcium, magnesium and the like, as well as from organic bases.

The compounds (I) of the present invention are prepared from aminolactam intermediates such as those of formula II. The preparation of these intermediates is described in the following reaction Schemes.

Benzo-fused lactams 3 wherein the lactam is a seven-membered ring are conveniently prepared from substituted tetralones 2 using known procedures. The substituted tetralones are, in some cases, commercially available or are prepared from a suitably substituted derivative of 4-phenylbutyric acid 1. Cyclization of 1 can be achieved by a
number of methods well known in the literature including treatment with polyphosphoric acid at elevated temperatures as shown in Scheme 1.

CONVERSION OF SUBSTITUTED TETRALONES 2 TO BENZOLACTAMS 3 CAN BE ACHIEVED BY A NUMBER OF METHODS FAMILIAR TO THOSE SKILLED IN THE ART. A SUITABLE METHOD INVOLVES THE USE OF HYDRAZOIC ACID (SCHMIDT OR CURTIUS REACTIONS) TO FORM THE SUBSTITUTED BENZOLACTAM 3.

[0022] Benzofused lactams wherein the lactam is an eight-membered ring (6) are prepared as described by D. H. Jones, et al, J. Chem. Soc. C, 2176-2181 (1969) by a series of analogous transformations starting from a substituted derivative of 5-phenylpentanoic acid 4 as shown in Scheme 2.
As illustrated in Scheme 3, an analogous sequence is employed in the construction of benzo-fused lactams containing nine-membered rings. The requisite benzocyclooctanone intermediate 8 is obtained by acid-catalyzed cyclization of the substituted 6-phenylhexanoic acid precursor 7 using the aforementioned conditions. Elaboration to the desired nine-membered lactam product 9 can be achieved directly, through the use of hydrazoic acid (Schmidt reaction) using conditions described by R. Huisgen, *et al*, *Ann.*, 586, 30-51 (1954); or, via Beckmann rearrangement of an intermediate oxime, as demonstrated by W.M. Schubert, *et al*, *J. Amer. Chem. Soc.*, 76, 5462-5465 (1954).
[0024] As shown in Scheme 4, 3-aminobenzolactam analogs wherein the lactam is a six-membered ring (14) are prepared from a substituted derivative of 2-nitrobenzyl chloride (or bromide) 10 by the method of A.L. Davis, et al, Arch. Biochem. Biophys., 102, 48-51 (1963) and references cited therein.
Benzo-fused aminolactam analogs containing a five-membered lactam are prepared by an analogous sequence from appropriately substituted derivatives of ethyl o-nitromandelate by the procedure of A.L. Davis, et al, J. Med. Chem., 16, 1043-1045 (1973), as shown in Scheme 5.
Conversion of substituted benzo-fused lactams to the requisite 3-amino derivatives can be achieved by a number of methods familiar to those skilled in the art, including those described by Watthey, et al, *J. Med. Chem.*, 28, 1511-1516 (1985) and references cited therein. One common route proceeds via the intermediacy of a 3-halo (chloro, bromo or iodo) intermediate which is subsequently displaced by a nitrogen nucleophile, typically azide. A useful method of forming the 3-iodobenzolactam intermediate 20 involves treating the benzolactam with two equivalents each of iodonitromethane and iodine at low temperature, as illustrated in Scheme 6 for the seven-membered ring analog 3.

[0026] Conversion of substituted benzo-fused lactams to the requisite 3-amino derivatives can be achieved by a number of methods familiar to those skilled in the art, including those described by Watthey, et al, *J. Med. Chem.*, 28, 1511-1516 (1985) and references cited therein. One common route proceeds via the intermediacy of a 3-halo (chloro, bromo or iodo) intermediate which is subsequently displaced by a nitrogen nucleophile, typically azide. A useful method of forming the 3-iodobenzolactam intermediate 20 involves treating the benzolactam with two equivalents each of iodonitromethane and iodine at low temperature, as illustrated in Scheme 6 for the seven-membered ring analog 3.
Elaboration of the iodobenzolactams to the desired aminolactam intermediate II is achieved by a two-step procedure illustrated in Scheme 6. Typically, iodobenzolactam is treated with sodium azide in N,N-dimethylformamide at 50-100°C to give the 3-azido derivative. Alternatively, tetramethylguanidinium azide in a solvent such as methylene chloride can be employed to achieve similar results. Hydrogenation with a metal catalyst, such as platinum on carbon, or alternatively, treatment with triphenylphosphine in wet toluene, results in formation of the amine derivative. Formation of the analogous derivatives of the eight- and nine-membered benzolactams is also achieved by the routes shown in Scheme 6.

Chiral aminobenzolactams are obtained by resolution of the racemates by classical methods familiar to those skilled in the art. For example, resolution can be achieved by formation of diastereomeric salts of the racemic amines with optically active acids such as D- and L-tartaric acid. Determination of absolute stereochemistry can be achieved...
in a number of ways including X-ray analysis of a suitable crystalline derivative.

[0029] A useful preparation of the chiral intermediate 27 is shown in Scheme 7.

**SCHEME 7**

Conversion of 1-tetralone to the seven-membered benzolactam 24 is achieved by Beckman rearrangement of the intermediate oxime 23. Treatment of 24 with iodine and hexamethyldisilazane gives the 3-iodo derivative 25 which is sequentially treated with ammonia and D-tartaric acid to give the diastereomeric D-tartrate salt 26 after recrystallization. Liberation of the free amine 27 is achieved by neutralization of the D-tartrate salt with potassium carbonate followed by extractive isolation.

[0030] Intermediates of Formula II wherein X is a sulfur atom are prepared by methods described in the literature.
and known to those skilled in the art. As illustrated in Scheme 8, the seven-membered ring analog 35 is prepared from a protected derivative of cysteine 29 by the method of Slade, et al, J. Med. Chem., 28, 1517-1521 (1985) and references cited therein (CBz is benzyloxycarbonyl).
Sulfoxide and sulfone intermediates 36 and 37 are prepared by oxidation of 32 with various oxidants such as sodium periodate or meta-chloroperbenzoic acid. Eight-membered ring intermediates of Formula II wherein X is sulfur can be prepared by an analogous route starting from derivatives of homo-cysteine.

Seven-membered ring analogs of Formula II wherein X is C=O can be prepared from derivatives of tryptophan as described in the Australian J. Chem., 33, 633-640 (1980). Seven-membered ring analogs of Formula II wherein X is CH=CH can be prepared from the aforementioned analogs wherein X is C=O. Treatment of 42 with chemical reducing agents such as sodium borohydride in a polar solvent such as methanol or ethanol results in reduction to give the secondary alcohol derivative 43 (X=CHOH).

Dehydration of 43 can be achieved by several methods described in the literature and familiar to those skilled.
in the art. For example, treatment of $43$ in an inert solvent, such as benzene, with a strong acid such as $p$-toluenesulfonic acid, can result in dehydration to the unsatured analog $44$.

\text{43} & \xrightarrow{p\text{-TsOH}} \text{44}
\end{align*} \]

[0035] Attachment of the amino acid sidechain to intermediates of formula II is accomplished by the route shown in Scheme 12. Coupling is conveniently carried out by the use of an appropriately protected amino acid derivative, such as that illustrated by formula IV, and a coupling reagent such as benzotriazol-1-yl oxytris(dimethylamino)phosphonium hexafluorophosphate ("BOP") or benzotriazol-1-yl oxytripyrrolidinophosphonium hexafluorophosphate ("PyBOP") in an inert solvent such as methylene chloride. Separation of unwanted side products, and purification of intermediates is achieved by chromatography on silica gel, employing flash chromatography (W.C. Still, M. Kahn and A. Mitra, J. Org. Chem., 43, 2923 (1978)) or by medium pressure liquid chromatography.
The protected amino acid derivatives IV are, in many cases, commercially available in t-butoxycarbonyl (BOC) or benzyloxycarbonyl (CBz) forms. A useful method to prepare the preferred sidechain is shown in Scheme 13.
[0037] Reaction of isobutylene with N-chlorosulfonylisocyanate 45 in diethyl ether gives the azetidinone derivative 46. Removal of the chlorosulfonyl group with aqueous sodium sulfite followed by reaction with di-t-butyldicarbonate gives the BOC-protected intermediate 48. Alkaline hydrolysis gives the protected amino acid derivative 49 in good overall yield.

[0038] Intermediates of formula VII are prepared as shown in Scheme 14 by treatment of the desired lactam intermediate V with an alkylating agent VI, wherein Y is a good leaving group such as Cl, Br, I, O-methanesulfonyl or O-(p-toluenesulfonyl). Alkylation of intermediates of formula V is conveniently carried out in anhydrous dimethyl formamide (DMF) in the presence of bases such as sodium hydride or potassium t-butoxide for a period of 0.5 to 24 hours at temperatures of 20-100°C. Substituents on the alkylating agent VI may need to be protected during alkylation. A description of such protecting groups may be found in: Protective Groups in Organic Synthesis, T.W. Greene, John Wiley and Sons, New York, 1981.
Alkylation agents VI are in some cases commercially available or may be prepared by methods described in the literature and familiar to one skilled in the art. Compounds of formula I where R₃a is a carbamate, semicarbazide or urea derivative, wherein this functionality is attached to the phenyl ring by a nitrogen atom are prepared from intermediate 50, obtained by alkylation with a derivative of formula VI wherein R₃a is a nitro group as shown in Scheme 15.

G is t-butoxycarbonyl or benzyloxy carbonyl
A useful method of synthesizing a preferred alkylating agent is shown in reaction Scheme 16.
[0041] Reaction of 4-tolylboronic acid 51 with 2-bromonitrobenzene 52 in the presence of a transition metal catalyst such as (tetrakis)triphenylphosphine palladium (0) in a mixed solvent system containing aqueous sodium hydroxide, water, 2-propanol and benzene at elevated temperatures for several hours gives the coupled product 53 in good overall yield. Chromatographic purification and separation of unwanted by-products is conveniently performed on silica, eluting with common organic solvents such as hexane, ethyl acetate and methylene chloride. Conversion of 53 to the bromide derivative 54 is accomplished by treatment with N-bromosuccinimide in refluxing carbon tetrachloride in the presence of a radical initiator such as benzoyl peroxide or 2,2'-azobisisobutyronitrile (AIBN).

[0042] As shown in Scheme 17, reduction of the nitro group of 50 is achieved by hydrogenation in the presence of a metal catalyst, such as palladium on carbon, in a protic solvent such as methanol or ethanol. It may be appreciated by one skilled in the art that for certain compounds where catalytic hydrogenation is incompatible with existing functionality, alternative methods of reduction are indicated, such as chemical reduction with stannous chloride under acidic conditions. It should also be noted that the protecting group G in intermediate 50 must be compatible with the experimental conditions anticipated for reduction. For example, intermediate 50 wherein G is t-butoxycarbonyl (BOC) is stable to the conditions of catalytic reduction employed in the conversion to 55. Intermediate 55 may also be further
elaborated to a new intermediate by reductive alkylation with an aldehyde by the aforementioned procedures.

Elaboration of 56 to carbamate compound 57 is achieved by reaction with the appropriate chloroformate reagent in pyridine or in methylene chloride with triethylamine as shown in Scheme 18.
Transformation of amine intermediate 56 to urea derivatives is accomplished in several ways. Terminally disubstituted compounds can be obtained directly by reaction of 56 with a disubstituted carbamoyl chloride 58 in an inert solvent such as methylene chloride in the presence of triethylamine or 4-dimethylaminopyridine. In addition, mono-substituted compound 61 wherein either R\textsubscript{12b} or R\textsubscript{12b} is hydrogen is obtained from 56 by reaction with an isocyanate 60 as shown in Scheme 19. Terminally unsubstituted urea 61, wherein R\textsubscript{12b} is hydrogen, is also prepared from amine 56 by reaction with trimethylsilyl isocyanate (60; R\textsubscript{12b} is (CH\textsubscript{3})\textsubscript{3}Si).

Alternatively, amine 55 is converted to an isocyanate 62 by treatment with phosgene or an equivalent reagent such as bis(trichloromethyl)carbonate (triphosgene) as indicated in Scheme 20. Subsequent reaction of 62 with primary or secondary amines in an inert solvent such as methylene chloride gives the corresponding urea derivative 59 in good yield. Oxidative rearrangement of 65 through the use of a peroxy-carboxylic acid (Baeyer-Villiger reaction) such as m-chloroperbenzoic acid gives the ester 66 which is hydrolyzed in the presence of a strong base such as sodium or lithium hydroxide to give phenol 67. Reaction of 67 with an isocyanate leads directly to carbamate 68. Additionally, treatment of 67 with N,N'-carbonyldiimidazole in dimethylformamide can form an activated intermediate which will react with substituted hydrazine reagents to give a carbazate product 69.

It may be appreciated by one skilled in the art that the protecting group G in 70 must therefore be compatible with the strongly acidic conditions.
employed for ester cleavage; hence G is taken as benzyloxy carbonyl. Conversion of the carboxylic acid to the benzylamine derivative 72 can be achieved by a five-step sequence consisting of: 1) formation of a mixed anhydride with isobutyl chloroformate; 2) reduction with sodium borohydride to the benzyl alcohol; 3) formation of the mesylate with methanesulfonyl chloride; 4) formation of the azide by reaction with sodium azide, and finally, 5) reduction of the azide with tin(II) chloride. The benzylamine intermediate 72 can be further elaborated to 73 by the aforementioned reductive amination procedure.

Conversion to the final products of formula I wherein R^4 is hydrogen, is carried out by simultaneous or sequential removal of all protecting groups from intermediate VII as illustrated in Scheme 26.
Removal of benzoyloxycarbonyl (CBz) groups can be achieved by a number of methods known in the art; for example, catalytic hydrogenation with hydrogen in the presence of a platinum or palladium catalyst in a protic solvent such as methanol. In cases where catalytic hydrogenation is contraindicated by the presence of other potentially reactive functionality, removal of benzoyloxycarbonyl groups can also be achieved by treatment with a solution of hydrogen bromide in acetic acid. Removal of t-butoxycarbonyl (BOC) protecting groups is carried out by treatment of a solution in a solvent such as methylene chloride or methanol, with a strong acid, such as hydrochloric acid or trifluoroacetic acid. Conditions required to remove other protecting groups which may be present can be found in Protective Groups in Organic Synthesis T.W. Greene, John Wiley and Sons, NY. 1981.

As shown in Scheme 27, compounds of formula I wherein R₄ and R₅ are each hydrogen can be further elaborated by reductive alkylation with an aldehyde by the aforementioned procedures or by alkylations such as by reaction with various epoxides. The products, obtained as hydrochloride or trifluoroacetate salts, are conveniently purified by reverse phase high performance liquid chromatography (HPLC) or by recrystallization.
It is noted that the order of carrying out the foregoing reaction schemes is not significant and it is within the skill of one skilled in the art to vary the order of reactions to facilitate the reaction or to avoid unwanted reaction products.

The growth hormone releasing compounds of Formula I are useful in vitro as unique tools for understanding how growth hormone secretion is regulated at the pituitary level. This includes use in the evaluation of many factors thought or known to influence growth hormone secretion such as age, sex, nutritional factors, glucose, amino acids, fatty acids, as well as fasting and non-fasting states. In addition, the compounds of this invention can be used in the evaluation of how other hormones modify growth hormone releasing activity. For example, it has already been established that somatostatin inhibits growth hormone release. Other hormones that are important and in need of study as to their effect on growth hormone release include the gonadal hormones, e.g., testosterone, estradiol, and progesterone; the adrenal hormones, e.g., cortisol and other corticoids, epinephrine and norepinephrine; the pancreatic and gastrointestinal hormones, e.g., insulin, glucagon, gastrin, secretin; the vasoactive intestinal peptides, e.g., bombesin; and the thyroid hormones, e.g., thyroxine and triiodothyronine. The compounds of Formula I can also be employed to investigate the possible negative or positive feedback effects of some of the pituitary hormones, e.g., growth hormone and endorphin peptides, on the pituitary to modify growth hormone release. Of particular scientific importance is the use of these compounds to elucidate the subcellular mechanisms mediating the release of growth hormone.

The compounds of Formula I can be administered to animals, including man, to release growth hormone in vivo. For example, the compounds can be administered to commercially important animals such as swine, cattle, sheep
and the like to accelerate and increase their rate and extent of growth, and to increase milk production in such animals. In addition, these compounds can be administered to humans in vivo as a diagnostic tool to directly determine whether the pituitary is capable of releasing growth hormone. For example, the compounds of Formula I can be administered in vivo to children. Serum samples taken before and after such administration can be assayed for growth hormone. Comparison of the amounts of growth hormone in each of these samples would be a means for directly determining the ability of the patient's pituitary to release growth hormone.

Accordingly, the present invention includes within its scope pharmaceutical compositions comprising, as an active ingredient, at least one of the compounds of Formula I in association with a pharmaceutical carrier or diluent. Optionally, the active ingredient of the pharmaceutical compositions can comprise a growth promoting agent in addition to at least one of the compounds of Formula I or another composition which exhibits a different activity, e.g., an antibiotic or other pharmaceutically active material.

Growth promoting agents include, but are not limited to, TRH, diethylstilbestrol, theophylline, enkephalins, E series prostaglandins, compounds disclosed in U.S. Patent No. 3,239,345, e.g., zeranol, and compounds disclosed in U.S. Patent No. 4,036,979, e.g., sulbenox or peptides disclosed in U.S. Patent No. 4,411,890.

A still further use of the disclosed novel benzo-fused lactam growth hormone secretagogues is in combination with other growth hormone secretagogues such as GHRP-6, GHRP-1 or GHRP-2 as described in U.S. Patent Nos. 4,411,890; and publications WO 89/07110 and WO 89/07111 and B-HT 920 or in combination with growth hormone releasing factor and its analogs or growth hormone and its analogs. A still further use of the disclosed novel benzo-fused lactam growth hormone secretagogues is in combination with ϵ2 adrenergic agonists or ϰ3 adrenergic agonists in the treatment of obesity or in combination with parathyroid hormone or bisphosphonates, such as MK-217 (alendronate), in the treatment of osteoporosis. A still further use of the disclosed novel benzo-fused lactam growth hormone secretagogues is in combination with IGF-1 to reverse the catabolic effects of nitrogen wasting as described by Kupfer, et al., J. Clin. Invest., 91, 391 (1993).

As is well known to those skilled in the art, the known and potential uses of growth hormone are varied and multitudinous. Thus, the administration of the compounds of this invention for purposes of stimulating the release of endogenous growth hormone can have the same effects or uses as growth hormone itself. These varied uses of growth hormone may be summarized as follows: stimulating growth hormone release in elderly humans; prevention of catabolic side effects of glucocorticoids; treatment of osteoporosis; stimulation of the immune system; treatment of retardation; acceleration of wound healing; accelerating bone fracture repair; treatment of growth retardation, treating renal failure or insufficiency resulting in growth retardation; treatment of physiological short stature, including growth hormone deficient children; treating short stature associated with chronic illness; treatment of obesity and growth retardation associated with obesity; treating growth retardation associated with Prader-Willi syndrome and Turner’s syndrome; accelerating the recovery and reducing hospitalization of burn patients; treatment of intrauterine growth retardation, skeletal dysplasia, hypercortisolism and Cushings syndrome; induction of pulsatile growth hormone release; replacement of growth hormone in stressed patients; treatment of osteochondrodysplasias, Noonans syndrome, schizophrenia, depression, Alzheimer’s disease, delayed wound healing, and psychosocial deprivation; treatment of pulmonary dysfunction and ventilator dependency; attenuation of protein catabolic response after a major operation; reducing cachexia and protein loss due to chronic illness such as cancer or AIDS. Treatment of hyperinsulinemia including nesidioblastosis; adjuvant treatment for ovulation induction; to stimulate thymic development and prevent the age-related decline of thymic function; treatment of immunosuppressed patients; improvement in muscle strength, mobility, maintenance of skin thickness, metabolic homeostasis, renal homeostasis in the frail elderly; stimulation of osteoblasts, bone remodelling, and cartilage growth; stimulation of the immune system in companion animals and treatment of disorders of aging in companion animals; growth promotant in livestock and stimulation of wool growth in sheep.

The compounds of this invention can be administered by oral, parenteral (e.g., intramuscular, intraperitoneal, intravenous or subcutaneous injection or implant), nasal, vaginal, rectal, sublingual, or topical routes of administration and can be formulated in dosage forms appropriate for each route of administration.

Solid dosage forms for oral administration include capsules, tablets, pills, powders and granules. In such solid dosage forms, the active compound is admixed with at least one inert pharmaceutically acceptable carrier such as sucrose, lactose, or starch. Such dosage forms can also comprise, as is normal practice, additional substances other than inert diluents, e.g., lubricating agents such as magnesium stearate. In the case of capsules, tablets and pills, the dosage forms may also comprise buffering agents. Tablets and pills can additionally be prepared with enteric coatings.

Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, the elixirs containing inert diluents commonly used in the art, such as water. Besides such inert diluents, compositions can also include adjuvants, such as wetting agents, emulsifying and suspending agents, and sweetening, flavoring and perfuming agents.

Preparations according to this invention for parenteral administration include sterile aqueous or non-aqueous solutions, suspensions, or emulsions. Examples of non-aqueous solvents or vehicles are propylene glycol, polyethylene glycol, vegetable oils, such as olive oil and corn oil, gelatin, and injectable organic esters such as ethyl oleate.
Such dosage forms may also contain adjuvants such as preserving, wetting, emulsifying, and dispersing agents. They may be sterilized by, for example, filtration through a bacteria-retaining filter, by incorporating sterilizing agents into the compositions, by irradiating the compositions, or by heating the compositions. They can also be manufactured in the form of sterile solid compositions which can be dissolved in sterile water, or some other sterile injectable medium immediately before use.

Compositions for rectal or vaginal administration are preferably suppositories which may contain, in addition to the active substance, excipients such as cocoa butter or a suppository wax.

Compositions for nasal or sublingual administration are also prepared with standard excipients well known in the art.

The dosage of active ingredient in the compositions of this invention may be varied; however, it is necessary that the amount of the active ingredient be such that a suitable dosage form is obtained. The selected dosage depends upon the desired therapeutic effect, on the route of administration, and on the duration of the treatment. Generally, dosage levels of between 0.0001 to 100 mg/Kg of body weight daily are administered to patients and animals, e.g., mammals, to obtain effective release of growth hormone.

The following examples are provided for the purpose of further illustration only and are not intended to be limitations on the disclosed invention.

**EXAMPLE 1**

**N-[1-[[2’-[(Methoxycarbonyl)amino][1,1’-biphenyl]-4-yl]methyl]-2,3,4,5-tetrahydro-2-oxo-1H-1-benzazepin-3(R)-yl]-3-amino-3-methylbutanamide, trifluoroacetate**

**Step A: 1-Tetralone oxime**

To 4.6 L of water at room temperature in a 4-neck 50 L flask sitting in a steam bath apparatus equipped with an overhead stirrer, a temperature probe and reflux condenser was added 3.72 Kg (27.36 mol) of sodium acetate with stirring, followed by 1.9 Kg of hydroxylamine hydrochloride (27.36 mol). To this slurry at room temperature, 12 L of ethanol was added followed by 1.994 Kg (13.68 mol) of 1-tetralone. Additional ethanol (1.7 L) was used to rinse off the funnel and added to the reaction mixture. The resulting light orange slurry was heated to 75°C over 40 minutes and maintained at 75-85°C for another 75 minutes. The reaction mixture was cooled with the aid of ice packed around the flask. When the internal temperature reached 32°C, the reaction mixture was pumped over 15 minutes into 60 L of ice contained in a 200 L vessel. The reaction vessel was washed with an additional 2 L of water which was added to the 200 L vessel. When the ice melted, the mixture was filtered through a filter pad and the wet cake washed with 4 L of water. The wet cake was suction dried for 1 hour then transferred to two trays and dried under vacuum at 40°C for 2 days to give 2.094 Kg (13.01 mol, 95%) of product. 1H NMR (250 MHz, CDCl₃): δ 2.24 (m, 2H), 2.38 (t, 6Hz, 2H), 2.82 (t, 6Hz, 2H), 7.03 (d, 8Hz, 1H), 7.13 (m, 2H), 7.24 (m, 2H), 8.63 (br s, 1H).

**Step B: 2,3,4,5-Tetrahydro-1H-1-benzazepin-2-one**

To 10 L of methanesulfonic acid in a 22 L 3-neck flask equipped with an overhead stirrer, a nitrogen inlet and reflux condenser, was added 2.6 Kg (18.61 mol) of phosphorus pentoxide. An additional 1.6 L of methanesulfonic acid was used to wash all the phosphorus pentoxide into the vessel. The mixture was heated at 90°C for 2.5 hours then cooled to 50°C using an ice bath and treated with 2.00 Kg (12.41 mol) of 1-tetralone oxime in several portions over 15 minutes. The mixture was heated at 63°C for 10 minutes then slowly heated to 80°C and kept at 80°C for 3 hours. The reaction mixture was pumped into 70 L of ice then treated slowly with 11.25 L of 50% aqueous sodium hydroxide over 90 minutes at such a rate so as to maintain the temperature below 28°C. The mixture was filtered and 4 L of the filtrate was used to rinse the vessel. The wet cake (pink) was washed with 8 L of water then suction dried for 45 minutes and transferred to two trays and dried under vacuum at 40°C for 2 days to give 2.094 Kg (13.01 mol, 95%) of product. 1H NMR (250 MHz, CDCl₃): δ 2.24 (m, 2H), 2.38 (t, 6Hz, 2H), 2.82 (t, 6Hz, 2H), 7.03 (d, 8Hz, 1H), 7.13 (m, 1H), 7.24 (m, 2H), 8.63 (br s, 1H).

**Step C: 3-Iodo-2,3,4,5-tetrahydro-1H-1-benzazepin-2-one**

A suspension of 1.8 Kg (11.17 mol) of 2,3,4,5-tetrahydro-1H-1-benzazepin-2-one in a mixture of 22.33 L of methylene chloride and 11.78 L (55.83 mol) of hexamethyldisilazane was heated at reflux for 10 minutes, then cooled to 30°C and treated with 8.503 Kg (33.5 mol) of iodine in one portion. The mixture was heated at reflux for 2.5 hours, then cooled to room temperature. Aqueous sodium sulfite containing 4.926 Kg of sodium sulfite in 4 L of water was cooled to 0°C and into it was poured the reaction mixture in several portions with vigorous stirring while maintaining
Step D: 3(R)-Amino-2,3,4,5-tetrahydro-1H-1-benzazepin-2-one, D-tartaric acid salt

[0073] 3-Iodo-2,3,4,5-tetrahydro-1H-1-benzazepin-2-one (1.79 Kg, 6.24 mol) was slurried in 6.2 L of methanol and the slurry charged into an autoclave. Condensed ammonia (1.55 L) was added and the autoclave closed, with stirring, and heated to 100°C over 1 hour. Heating at 100°C was continued for 2 hours then the autoclave was allowed to cool to room temperature over 1 hour, during which time the internal pressure was 150-155 psi. The reaction mixture was transferred to a polyethylene jug and the autoclave rinsed with 2x8 L of methanol. The washings were concentrated under vacuum at 30°C then combined with the reaction mixture and concentrated to near dryness under vacuum at 30°C. The resulting residue was dissolved in 4 L of ethyl acetate then concentrated to dryness under vacuum at 30°C.

[0074] Sodium chloride (712 g) was dissolved in 2 L of water and 1.0 Kg of sodium carbonate was dissolved in 6 L of water. Two liters of the sodium carbonate solution was added to the concentrated residue and the resulting slurry transferred to an extraction flask. Another 2 L portion of the sodium carbonate solution was added to the residue flask and the solution transferred to the extraction flask. The remaining sodium carbonate solution was used in the same way. The sodium chloride solution was added to the sodium carbonate/aminolactam emulsion and the resulting mixture stirred for 10 minutes then extracted with four 6 L portions of methylene chloride. The combined methylene chloride layers were concentrated to dryness; the residue was treated with 2 L of 200 proof ethanol and the resulting slurry concentrated to dryness under vacuum to give 1.171 Kg of crude product.

[0075] The crude product was slurried in 8 L of ethanol and treated with 900 g of D-tartaric acid in one portion. Water (7 L) was added and the mixture heated to 77°C, then additional ethanol (45 L) was added and heating continued. The solution was cooled to 43°C and treated with the seed slurry. (The seed slurry was prepared by the route described above starting with 10.50 g of crude product and 9.1 g of D-tartaric acid.) The solution was aged at room temperature for 48 hours. The slurry formed was removed by filtration and the wet cake washed with 1.8 L of 1.8% ethyl acetate. The resulting filter cake was washed with nitrogen bleeding for 20 hours, then transferred into a drying tray and dried under vacuum for 24 hours to give 354 g (1.085 mol, 17.4%) of the product. 1H NMR (200 MHz, CDCl3): δ 2.13 (m, 1H), 2.51 (m, 2H), 2.73 (m, 2H), 3.68 (t, 6Hz, 1H), 3.98 (s, 2H), 7.05 (d, 8Hz, 1H), 7.16 (t, 8Hz, 1H), 7.30 (m, 2H), 7.6 (br s, 5H), 10.26 (br s, 1H).

Step E: 3(R)-Amino-2,3,4,5-tetrahydro-1H-1-benzazepin-2-one

[0076] A solution of 229.23 g (0.700 mol) of 3(R)-amino-2,3,4,5-tetrahydro-1H-1-benzazepin-2-one, D-tartarate in 4.1 L of water was treated with 194 g (1.40 mol) of potassium carbonate. Subsequent portions of 100 g and 135 g of potassium carbonate were added until the pH was 10.5. The mixture was extracted with four 4 L portions of methylene chloride which were then combined and dried over magnesium sulfate. The aqueous layer was treated with 55 L of toluene and concentrated under vacuum to give 115.5 g of product which contained 1.6% of an impurity identified as 7-iodo-3(R)-amino-2,3,4,5-tetrahydro-1H-1-benzazepin-2-one.

[0077] A solution of 107.02 g (0.607 mol) of the intermediate obtained above in 1.712 L of ethanol was hydrogenated at room temperature and 40 psi over 4.00 g of 10% palladium on carbon for 4 hours. Step F: 4,4-Dimethylazetidin-2-one

[0078] A 3-neck 3 L round bottom flask equipped with a magnetic stirrer, thermometer, cold finger condenser and nitrogen bubbler was charged with 1 L of ether. The flask was cooled to -65°C and into it was condensed 500-600 mL of isobutylene. The cold finger condenser was replaced with a dropping funnel and 200 mL (325 g, 2.30 mol) of chlorosulfonyl isocyanate was added dropwise over 1.5 hours. The mixture was maintained at -65°C for 1.5 hours then the dry ice/acetone cooling bath replaced with methanol/ice and the internal temperature slowly increased to -5°C at

which time the reaction initiated and the internal temperature rose to 15°C with evolution of gas. The internal temperature remained at 15°C for several minutes then dropped back down to -5°C and the mixture stirred at -5°C for 1 hour. The methanol/ice bath was removed and the reaction mixture warmed to room temperature and stirred overnight.

[0079] The reaction mixture was transferred to a 3-neck 12 L round bottom flask fitted with a mechanical stirrer and diluted with 2 L of ether. The well stirred reaction mixture was treated with 2 L of saturated aqueous sodium sulfite. After 1 hour, an additional 1 L of saturated aqueous sodium sulfite was added followed by sufficient sodium bicarbonate to adjust the pH to approximately 7. The mixture was stirred another 30 minutes then the layers allowed to separate. The ether layer was removed and the aqueous layer reextracted with 2x1 L of ether. The combined ether extracts were washed once with 500 mL of saturated aqueous sodium bicarbonate and once with 500 mL of saturated aqueous sodium chloride. The ether layer was removed, dried over magnesium sulfate, filtered and concentrated under vacuum to give 33 g of a pale yellow oil. The aqueous layer was made basic by the addition of solid sodium bicarbonate and extracted with 3x1 L of ether. The combined ether extracts were washed and dried as described above, then combined with the original 33 g of pale yellow oil and concentrated under vacuum to give 67.7 g of product. Further extraction of the aqueous layer with 4x1 L of methylene chloride and washing and drying as before gave an additional 74.1 g of product. Still further extraction of the aqueous layer with 4x1 L of methylene chloride gave an additional 21.9 g of product. The organic layer was removed, dried over magnesium sulfate, filtered and solvents removed under vacuum. The residue was purified by medium pressure liquid chromatography on silica, eluting with 5% methanol in ethyl acetate, to give 33 mg (0.062 mmol, 95%) of the product as a colorless glass. 

[0251] A solution of 33 mg (0.062 mmol) of the intermediate obtained in Step D in 2 mL of methanol at room temperature was treated with 0.5 mL of concentrated hydrochloric acid. After 2 hours, solvents were removed under vacuum and the residue further dried under high vacuum for 1 hour.

[0252] The amine hydrochloride obtained above was taken up in 1 mL of methylene chloride and treated with 13 mg (0.064 mmol, 1.03 eq.) of N-t-butoxycarbonyl-a-methylalanine, 26 μL of triethylamine (19 mg, 0.19 mmol, 3 eq.) and finally, 49 mg (0.094 mmol, 1.5 eq.) of benzotriazol-1-yloxytrypyrrolidinophosphonium hexafluorophosphate. After stirring at room temperature for 1 hour, the reaction mixture was diluted into 10 mL of ethyl acetate and washed with 5% aqueous citric acid, saturated aqueous sodium bicarbonate and saturated aqueous sodium chloride. The organic layer was removed, dried over magnesium sulfate, filtered and solvents removed under vacuum. The residue was purified by medium pressure liquid chromatography on silica, eluting with ethyl acetate, to give 37 mg (0.060 mmol, 96%) of the product as a clear glass. 

Step F: 2-Amino-2-methyl-N-[2,3,4,5-tetrahydro-1-[[2'-[[methoxycarbonyl]amino]methyl][1,1'-biphenyl]-4-yl]methyl]-1H-benzazepin-3(R)-yl]propanamide, trifluoroacetate

[0253] A solution of 35 mg (0.057 mmol) of the intermediate obtained in Step E in 1 mL of methanol at room temperature was treated with 0.5 mL of concentrated hydrochloric acid. After 3 hours, solvents were removed under vacuum and the residue purified by medium pressure liquid chromatography on C8, eluting with ethyl acetate/0.1% aqueous trifluoroacetic acid (65:35), to give 35 mg (0.055 mmol, 98%) of the title compound as a colorless glass.

FAB-MS: calculated for C$_{41}$H$_{46}$N$_4$O$_6$ 690; found 691 (M+H, 3%), 591 (M-BOC, 100%).

Step C: 2-Amino-2-methyl-N-[2,3,4,5-tetrahydro-1-[[2'-[[[benzyloxycarbonyl]amino]methyl][1,1'-biphenyl]-4-yl]methyl]-2-oxo-1H-benzazepin-3(R)-yl]propanamide, trifluoroacetate

[0256] The title compound was prepared from the intermediate obtained in Step B by the procedure described in Example 59, Step F. $^1$H NMR (400 MHz, CD$_3$OD): $\delta$ 1.54 (s, 3H), 1.64 (s, 3H), 2.27 (m, 2H), 2.60 (m, 2H), 4.16 (s, 2H), 4.39 (dd; 7, 11 Hz; 1H), 5.00 (d, 15Hz, 1H), 5.05 (s, 2H), 5.22 (d, 15Hz, 1H), 7.14 (d, 8 Hz, 1H), 7.20-7.40 (m, 11H). FAB-MS: calculated for C$_{36}$H$_{38}$N$_4$O$_4$ 590; found 591 (M+H, 100%).
