Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention.)
Description

FIELD OF THE INVENTION

[0001] The present invention relates to novel peptides being variants of an epitope of the human 60kDa heat shock protein (hsp 60) and to pharmaceutical compositions comprising them and methods for the diagnosis and treatment of insulin-dependent diabetes mellitus (IDDM) using such peptides.

BACKGROUND OF THE INVENTION

[0002] Type I diabetes, or IDDM, is an autoimmune disease caused by T cells that attack and destroy the insulin producing β-cells located in the islets of the pancreas (Castano and Eisenbarth, 1990). The autoimmune process culminating in IDDM begins and progresses without symptoms. The disease surfaces clinically only when the cumulative loss of β-cells exceeds the capacity of the residual β-cells to supply insulin. Indeed, the collapse of glucose homeostasis and clinical IDDM is thought to occur only after 80-90% of the β-cells have been inactivated by the immune system. Thus, patients who can be identified as suffering from IDDM are bound to be in an advanced stage of autoimmune destruction of their β-cells. Moreover, diagnosis of incipient, pre-clinical diabetes by the detection of immunological markers of β-cell autoimmunity can be made only after the onset of the autoimmune process. Therefore, the therapeutic quest is to find a safe, specific and effective way to turn off an autoimmune process that is already well underway.

[0003] The present inventors have examined this question before by studying the spontaneous diabetes developing in mice of the NOD strain, which is considered to be a faithful model of human IDDM (Castano and Eisenbarth, 1990). NOD mice develop insulitis around 4 weeks of age, which begins as a mild peri-islet infiltrate and progresses to severe intra-islet inflammation. Hyperglycemia, which attests to insulin insufficiency, begins in the females in our colony at about 14-17 weeks of age. By 35-40 weeks of age, almost all the female NOD mice have developed severe diabetes and most die in the absence of insulin treatment. Male NOD mice have a lower incidence of disease, for reasons that are not clear. The diabetes of NOD mice has been shown to be caused by autoimmune T cells (Bendelac et al., 1987).

[0004] T cell reactivity and autoantibodies to various antigens have been detected in human IDDM patients as well as in NOD mice (Elias, 1994), and it is not clear whether immunity to any single one of the possible target antigens is the primary cause of the disease. Beyond the question of causation is the question of therapy.

[0005] It has been demonstrated that the initiation of the autoimmune process in NOD mice can be prevented by subjecting the mice, before the onset of diabetes, to various manipulations such as restricted diet, viral infections, or non-specific stimulation of the immune system (Bowman et al., 1994). NOD diabetes is also preventable by induction of immunological tolerance in pre-diabetic mice to the antigen glutamic acid decarboxylase (GAD) (Kaufman et al., 1993; Tisch et al., 1993).

[0006] The present inventors have found previously that the diabetes of NOD mice can be prevented by T cell vaccination using T cells specific for the p277 peptide sequence of the human hsp60 molecule (Elias et al., 1991). This protein was formerly designated hsp65, but is now designated hsp60 in view of more accurate molecular weight information; by either designation, the proteins are the same.

[0007] The p277 peptide, being the epitope of the human hsp60 involved in IDDM and corresponding to positions 437-460 of the human hsp60 sequence, was first described in Israeli Patent Application No. 94241 of the present applicant and in Elias and Cohen, 1994, and has the following sequence:

Val-Leu-Gly-Gly-Gly-Cys-Ala-Leu-Leu-Arg-Cys-Ile-Pro-Ala-Leu-Asp-Ser-Leu-Thr-Pro-Ala-Asn-Glu-Asp (SEQ ID NO:1)

Administration of the p277 peptide itself at the onset of insulitis was shown also to prevent the development of diabetes, probably by down-regulating the anti-p277 immunity that is essential for NOD diabetes (Elias et al., 1991; Israeli Patent Application No. 94241). Recent studies have indicated that the p277 peptide may also be used to reverse β-Cell autoimmunity that has progressed to an advanced stage (Elias and Cohen, 1994).

[0008] The laboratory of the present inventors has recently reported that a form of autoimmune diabetes can be induced in the C57BL/KsJ strain of mice by the administration of a very low dose of the b-cell toxin streptozotocin (STZ) (Elias et al., 1994). Whereas the standard low dose of STZ of 40 mg/kg administered daily for 5 days usually induces clinical diabetes within 3 weeks, the administration of 30 mg/kg for 5 days induces clinical diabetes only after a lag
period of about 3 months. This model of induced diabetes is marked by the appearance in the prodrome period of autoantibodies to insulin, anti-idiotypic antibodies to the insulin autoantibodies, and autoantibodies to hsp60. The mice also manifest spontaneous T-cell reactivity to hsp60 and to its p277 peptide (Elias et al., 1994). Thus, the lower than standard low dose of STZ appears to trigger an autoimmune process not unlike that observed in the spontaneous diabetes developing in NOD mice (Elias et al., 1990).

**SUMMARY OF THE INVENTION**

In a study of fragments and variants of the peptide p277, it was unexpectedly found that the peptides in which the sole threonine residue was replaced by a lysine residue and/or one or both of the cysteine residues were replaced by valine residue(s), were active as p277 in the treatment of diabetes. These results were even more surprising since the substitution of the cysteine residues by serine residues resulted in inactive peptides.

**0010** The present invention thus relates to a peptide comprising the sequence I:

\[
\text{Val-Leu-Gly-Gly-Gly-}X_1\text{-Ala-Leu-Leu-Arg-}X_2\text{-Ile-Pro-}
\]

Wherein \(X_1\) and \(X_2\) each is a Cys or Val residue and \(X_3\) is a Thr or Lys residue, but \(X_1\) and \(X_2\) cannot both be Cys residues when \(X_3\) is a Thr residue.

**0012** In specific embodiments of the invention, the peptide consists of the sequence I wherein both \(X_1\) and \(X_2\) are Cys and \(X_3\) is Lys, herein p277(Lys\(^{19}\)) (SEQ ID NO:3) or \(X_1\) is Val, \(X_2\) is Cys and \(X_3\) is Thr or Lys, herein p277(Val\(^{6}\)) (SEQ ID NO:4) and p277(Val\(^{6}\)-Lys\(^{19}\)) (SEQ ID NO:5), respectively; or \(X_1\) is Cys, \(X_2\) is Val and \(X_3\) is Thr or Lys, herein p277(Val\(^{11}\)) (SEQ ID NO:6) and p277(Val\(^{11}\)-Lys\(^{19}\)) (SEQ ID NO:7), respectively; or both \(X_1\) and \(X_2\) are Val and \(X_3\) is Thr or Lys, herein p277(Val\(^{6}\)-Val\(^{11}\)) (SEQ ID NO:8) and p277(Val\(^{6,11}\)-Lys\(^{19}\)) (SEQ ID NO:9), respectively. The p277 (Val\(^{6}\)-Val\(^{11}\)) peptide is also referred to herein as p277(V).

**0013** It is further an object of the present invention to provide methods and kits for the early diagnosis of IDDM using a peptide of sequence I of the invention. In the course of developing IDDM, animals express hsp60 molecules, or molecules which are cross-reactive therewith, which find their way into the blood and urine of the animals. They also express antibodies and T cells directed specifically to such molecules. Thus, the presence of hsp60 (or molecules which are cross-reactive therewith) or antibodies or T cells specific thereto in blood or urine, serves as an assay for the detection of the IDDM process before the destruction of beta cells is completed and the individual is doomed to life-long diabetes.

**0014** The presence or incipience of IDDM in a patient can be diagnosed by testing the blood or urine of said patient for the presence of anti-hsp60 antibodies or T cells which are immunologically reactive with human hsp60, using as antigen a peptide of sequence I of the invention. Indeed, any of the procedures previously described as being operable using peptide p277, such as those described in PCT International Application published under No. WO 90/10449, can also be used substituting for p277 a peptide of sequence I of the present invention.

**0015** Accordingly, the present invention provides a method for diagnosing the presence or incipience of IDDM in a patient, comprising testing said patient for the presence of anti-hsp60 antibodies or of a T cell which immunoreacts with hsp60, whereby a result indicating the positive presence of anti-hsp60 antibodies, of a T cell which immunoreacts with hsp60, or of a T cell or of a T cell which immunoreacts with hsp60, indicates a high probability of the presence or incipience of IDDM.

**0016** In the method for diagnosing IDDM, the patient may be tested for the presence of anti-hsp60 antibodies, wherein said test method may comprise a radioimmunoassay or an ELISA test.

**0017** The patient may also be tested for the presence of a T cell which immunoreacts with hsp60. In one embodiment of this aspect, the test method comprises a T cell proliferation test comprising the steps:

(i) preparing a mononuclear cell fraction containing T cells from a blood sample obtained from said patient;
(ii) adding to said mononuclear cell fraction an antigen selected from a peptide of sequence I of the invention;
(iii) incubating said cell fraction in the presence of said antigen for a suitable period of time and under suitable culture conditions;
In step (iv), above, said labeled nucleotide is preferably $^3$H-thymidine. The determination of the amount of proliferating T cells is made by calculation of the stimulation index of the T cells by standard methods.

In another embodiment of this aspect of the invention, the test method comprises a T-cell cytokine response test, in which steps (i) to (iii) are as in the above T cell proliferation test, and in a fourth step (iv) the presence of cytokine, such as IFN-γ, IL-2, IL-4, IL-6, IL-10, TNFα or TGFβ, secreted by the responding lymphocytes into the medium, is detected by standard methods with commercially available kits.

In another aspect, the invention provides an in vivo method wherein an antigen selected from a peptide of sequence I is injected subcutaneously into a patient and the occurrence of a detectable skin reaction (DTH) is observed.

The present invention also relates to means for performing such assays, as well as kits for performing such assays. The kits may be prepared for carrying out any of the various assays used for accomplishing the present invention. Each such kit includes all of the materials necessary to conduct a single assay or a fixed number of assays. For example, such a kit for determining the presence of anti-hsp60 antibodies may contain a solid-phase immobilized peptide of sequence I and a tagged antibody capable of recognizing the non-variable region of the anti-hsp60 antibody to be detected, such as tagged anti-human Fab. The kit may also contain directions for using the kit and containers to hold the materials of the kit. Any conventional tag or label may be used, such as a radioisotope, an enzyme, a chromophore or a fluorophore. A typical radioisotope is iodine-125 or sulfur-35. Typical enzymes for this purpose include horseradish peroxidase, β-galactosidase and alkaline phosphatase.

A kit for diagnosing the presence of IDDM by testing for the presence of anti-hsp60 antibodies comprises:

(i) an antigen selected from a peptide of sequence I; and
(ii) a tagged antibody capable of recognizing the non-variable region of said anti-hsp60 antibodies to be detected.

A kit for diagnosing the presence of IDDM by testing for the presence of a T cell which immunoreacts with hsp60 comprises:

(i) an antigen selected from a peptide of sequence I;
(ii) a suitable medium for culture of lymphocytes (T cells); and
(iii) either a labeled nucleotide for the T cell proliferation test, or a cytokine, e.g., IFN-γ, IL-2, IL-4, IL-6, IL-10, TNFα or TGFβ, assay kit, for the cytokine test.

For the in vivo test, the kit will comprise only a peptide of sequence I in a suitable form for injection.

The present invention further relates to means for preventing or treating IDDM. Vaccination with the antigen peptide sequence I is injected subcutaneously into the patient and the occurrence of a detectable skin reaction (DTH) is observed. In another aspect, the invention provides an in vivo method wherein an antigen selected from a peptide of sequence I is injected subcutaneously into a patient and the occurrence of a detectable skin reaction (DTH) is observed.

The present invention also relates to means for performing such assays, as well as kits for performing such assays. The kits may be prepared for carrying out any of the various assays used for accomplishing the present invention. Each such kit includes all of the materials necessary to conduct a single assay or a fixed number of assays. For example, such a kit for determining the presence of anti-hsp60 antibodies may contain a solid-phase immobilized peptide of sequence I and a tagged antibody capable of recognizing the non-variable region of the anti-hsp60 antibody to be detected, such as tagged anti-human Fab. The kit may also contain directions for using the kit and containers to hold the materials of the kit. Any conventional tag or label may be used, such as a radioisotope, an enzyme, a chromophore or a fluorophore. A typical radioisotope is iodine-125 or sulfur-35. Typical enzymes for this purpose include horseradish peroxidase, β-galactosidase and alkaline phosphatase.

A kit for diagnosing the presence of IDDM by testing for the presence of anti-hsp60 antibodies comprises:

(i) an antigen selected from a peptide of sequence I; and
(ii) a tagged antibody capable of recognizing the non-variable region of said anti-hsp60 antibodies to be detected.

A kit for diagnosing the presence of IDDM by testing for the presence of a T cell which immunoreacts with hsp60 comprises:

(i) an antigen selected from a peptide of sequence I;
(ii) a suitable medium for culture of lymphocytes (T cells); and
(iii) either a labeled nucleotide for the T cell proliferation test, or a cytokine, e.g., IFN-γ, IL-2, IL-4, IL-6, IL-10, TNFα or TGFβ, assay kit, for the cytokine test.

For the in vivo test, the kit will comprise only a peptide of sequence I in a suitable form for injection.

The present invention further relates to means for preventing or treating IDDM. Vaccination with the antigen peptide sequence I is injected subcutaneously into the patient and the occurrence of a detectable skin reaction (DTH) is observed. In another aspect, the invention provides an in vivo method wherein an antigen selected from a peptide of sequence I is injected subcutaneously into a patient and the occurrence of a detectable skin reaction (DTH) is observed.

The present invention also relates to means for performing such assays, as well as kits for performing such assays. The kits may be prepared for carrying out any of the various assays used for accomplishing the present invention. Each such kit includes all of the materials necessary to conduct a single assay or a fixed number of assays. For example, such a kit for determining the presence of anti-hsp60 antibodies may contain a solid-phase immobilized peptide of sequence I and a tagged antibody capable of recognizing the non-variable region of the anti-hsp60 antibody to be detected, such as tagged anti-human Fab. The kit may also contain directions for using the kit and containers to hold the materials of the kit. Any conventional tag or label may be used, such as a radioisotope, an enzyme, a chromophore or a fluorophore. A typical radioisotope is iodine-125 or sulfur-35. Typical enzymes for this purpose include horseradish peroxidase, β-galactosidase and alkaline phosphatase.

A kit for diagnosing the presence of IDDM by testing for the presence of anti-hsp60 antibodies comprises:

(i) an antigen selected from a peptide of sequence I; and
(ii) a tagged antibody capable of recognizing the non-variable region of said anti-hsp60 antibodies to be detected.

A kit for diagnosing the presence of IDDM by testing for the presence of a T cell which immunoreacts with hsp60 comprises:

(i) an antigen selected from a peptide of sequence I;
(ii) a suitable medium for culture of lymphocytes (T cells); and
(iii) either a labeled nucleotide for the T cell proliferation test, or a cytokine, e.g., IFN-γ, IL-2, IL-4, IL-6, IL-10, TNFα or TGFβ, assay kit, for the cytokine test.

For the in vivo test, the kit will comprise only a peptide of sequence I in a suitable form for injection.

The present invention further relates to means for preventing or treating IDDM. Vaccination with the antigen peptide sequence I is injected subcutaneously into the patient and the occurrence of a detectable skin reaction (DTH) is observed. In another aspect, the invention provides an in vivo method wherein an antigen selected from a peptide of sequence I is injected subcutaneously into a patient and the occurrence of a detectable skin reaction (DTH) is observed.

The present invention also relates to means for performing such assays, as well as kits for performing such assays. The kits may be prepared for carrying out any of the various assays used for accomplishing the present invention. Each such kit includes all of the materials necessary to conduct a single assay or a fixed number of assays. For example, such a kit for determining the presence of anti-hsp60 antibodies may contain a solid-phase immobilized peptide of sequence I and a tagged antibody capable of recognizing the non-variable region of the anti-hsp60 antibody to be detected, such as tagged anti-human Fab. The kit may also contain directions for using the kit and containers to hold the materials of the kit. Any conventional tag or label may be used, such as a radioisotope, an enzyme, a chromophore or a fluorophore. A typical radioisotope is iodine-125 or sulfur-35. Typical enzymes for this purpose include horseradish peroxidase, β-galactosidase and alkaline phosphatase.

A kit for diagnosing the presence of IDDM by testing for the presence of anti-hsp60 antibodies comprises:

(i) an antigen selected from a peptide of sequence I; and
(ii) a tagged antibody capable of recognizing the non-variable region of said anti-hsp60 antibodies to be detected.

A kit for diagnosing the presence of IDDM by testing for the presence of a T cell which immunoreacts with hsp60 comprises:

(i) an antigen selected from a peptide of sequence I;
(ii) a suitable medium for culture of lymphocytes (T cells); and
(iii) either a labeled nucleotide for the T cell proliferation test, or a cytokine, e.g., IFN-γ, IL-2, IL-4, IL-6, IL-10, TNFα or TGFβ, assay kit, for the cytokine test.

For the in vivo test, the kit will comprise only a peptide of sequence I in a suitable form for injection.
comprising a pharmaceutically acceptable carrier and, as active principle, an effective amount of a peptide of sequence I, a salt or a functional derivative thereof. The pharmaceutically acceptable carrier is preferably an oil vehicle such as an emulsion of mineral oil known as incomplete Freund's adjuvant (IFA). However, IFA, as well as complete Freund's adjuvant (CFA; a preparation of mineral oil containing various amounts of killed organisms of Mycobacterium) are not allowed for human use because the mineral oil is not metabolizable and cannot be degraded by the body.

[0029] It has now been found by the present inventors that certain fat emulsions, which have been in use for many years for intravenous nutrition of human patients, can also act as a vehicle for peptide therapy using the peptides of the present invention. Two examples of such emulsions are the available commercial fat emulsions known as Intralipid and Lipofundin. "Intralipid" is a registered trademark of Kabi Pharmacia, Sweden, for a fat emulsion for intravenous nutrition, described in US patent no. 3,169,094. "Lipofundin" is a registered trademark of B. Braun Melsungen, Germany. Both contain soybean oil as fat (100 or 200 g in 1,000 ml distilled water: 10% or 20%, respectively). Egg-yolk phospholipids are used as emulsifiers in Intralipid (12 g/l distilled water) and egg-yolk lecithin in Lipofundin (12 g/l distilled water). Isotonicity results from the addition of glycerol (25 g/l) both in Intralipid and Lipofundin.

[0030] The invention further relates to a method of preventing or treating IDDM which comprises administering to a patient in need thereof a pharmaceutical composition comprising a peptide of sequence I or a preparation comprising T cells which have developed specificity to said peptide of sequence I of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0031]  

Fig. 1 is a graph showing the stability of p277 and p277(Val\(^8\)-Val\(^{11}\)). The closed circles designate results using p277 and the open circles p277(Val\(^8\)-Val\(^{11}\)). The large circles represent results after 1 week of storage, the medium-size circles after 9 weeks, and the smallest circles after 20 weeks.

Fig. 2 shows that NOD T cells of the diabetogenic clone C9 proliferate in response to the peptides p277 (closed circles) and p277(Val\(^8\)-Val\(^{11}\)) (open circles).

Fig. 3 shows that NOD spleen T cells proliferate in the presence of the peptide p277(Lys\(^{19}\)). The spleens of 5 female NOD mice were tested in each age group for T cell proliferation in response to the peptides p277(Lys\(^{19}\)) (closed circles), p277 (open circles) and control peptide p278 (closed squares).

Fig. 4 shows that NOD T cells of the diabetogenic clone C9 proliferate in response to the peptide p277(Lys\(^{19}\)).

Fig. 5 is a graph showing the effectiveness of pretreatment with p277(V) in IFA in the prevention of STZ-induced diabetes as compared to control treatment or treatment with GADp34.

DETAILED DESCRIPTION OF THE INVENTION

[0032] Whenever a "peptide of sequence I" is mentioned in the invention, also salts and functional derivatives thereof are contemplated, as long as the biological activity of the peptide with respect to diabetes is maintained.

[0033] "Salts" of the peptide I contemplated by the invention are physiologically acceptable organic and inorganic salts.

[0034] "Functional derivatives" of the peptide I as used herein covers derivatives which may be prepared from the functional groups which occur as side chains on the residues or the N- or C- terminal groups, by means known in the art, and are included in the invention as long as they remain pharmaceutically acceptable, i.e., they do not destroy the activity of the peptide insofar as its similarity to the known activity of p277 is concerned, do not confer toxic properties on compositions containing it and do not adversely affect the antigenic properties thereof. Such "functional derivatives" are not intended to comprehend such changes which effectively convert one amino acid to another.

[0035] Subject to the above qualifications, these derivatives may, for example, include aliphatic esters of the carboxyl groups, amides of the carboxyl groups produced by reaction with ammonia or with primary or secondary amines, N-acyl derivatives of free amino groups of the amino acid residues formed by reaction with acyl moieties (e.g., alkanoyl or carbocyclic acroyl groups) or O-acyl derivatives of free hydroxyl group (for example that of seryl or threonyl residues) formed by reaction with acyl moieties.

[0036] The peptide of sequence I of the invention can be used as immunogen in pharmaceutical compositions, particularly vaccines for the alleviation and treatment of IDDM, as well as an antigen in diagnostic compositions for the diagnosis of IDDM. These pharmaceutical and diagnostic compositions, which may be prepared in a manner known in the art, also form part of the present invention.

[0037] When used for therapeutic treatment or as a prophylactic vaccine, the peptide of the present invention is preferably administered with a biologically active carrier which promotes the TH1→TH2 shift of the auto immune T cells. T cells of the CD4 helper type are classified in two groups according to the cytokines they secrete when activated (Mosmann and Coffman, 1989): TH1 cells secrete IL-2 and IFN-γ, while TH2 cells secrete IL-4 and IL-10. Such a
vehicle is preferably a fat emulsion comprising 10-20% triglycerides of plant and/or animal origin, 1.2-2.4% phospholipids of plant and/or animal origin, 2.25-4.5% osmo-regulator, 0-0.5% antioxidant, and sterile water to 100%. Such vehicle is most preferably Intralipid or Lipofundin. Use of such vehicles is described in an Israeli patent application No. 122755 filed on even date with the date of filing of the Israeli application on the present invention No. 116499, with the same applicant as the present application.

[0038] The therapeutic composition in accordance with the present invention may be administered orally or parenterally, such as subcutaneously, intramuscularly, intravenously, intranasally or intrarectally.

[0039] The examples herein establish the effectiveness of therapeutic treatment with the compounds and compositions of the present invention in scientifically accepted animal models of human IDDM.

EXAMPLES Materials and Methods

[0040]

(i) Mice. Inbred female mice of the NOD/Lt strain were supplied by the Animal Breeding Center of the Weizmann Institute of Science, Rehovot, Israel. These mice spontaneously develop autoimmune diabetes at 14 to 17 weeks of age that mimics IDDM in humans.

(ii) Peptides. Peptides were synthesized by standard Fmoc chemistry using an ABIMED synthesizer (FRG) and purified on HPLC by reverse phase chromatography. Sequences were confirmed by amino acid analysis. The following peptides were synthesized: the p277 peptide; the control peptide p278 of the sequence: Asn-Glu-Asp-Gln-Lys-Ile-Gly-Ile-Glu-Ile-Ile-Lys-Arg-Thr-Leu-Lys-Ile (SEQ ID NO: 10), corresponding to positions 458-474 of the human hsp60 molecule; fragments of p277: the amino half of p277 (p277.N), the carboxy half of p277 (p277.C), and p277C combined with p278 (p277.C-p278); the peptide p277(Lys19); and peptide p277 with various amino acid substitutions for the two cysteine residues in the sequence as follows: p277 with bridged -SH groups (p277(bridged Cys-Cys)); p277 with both cysteine residues replaced by valine (p277(Val6-Ser11)); or by serine (p277(Ser6-Ser11)).

(iii) Treatment and follow-up. Mice were treated with emulsions of p277, of the other peptides, or of bovine serum albumin (BSA, purchased from Sigma, St. Louis, MO, USA) in volumes of 0.1 ml injected subcutaneously into the back. The antigens were diluted in PBS and emulsified in an equal volume of mineral oil (incomplete Freund's adjuvant (IFA); Sigma) or 10% Intralipid. The mice were tested for blood glucose levels at 10 A.M. in a non-fasting state as described (Elias et al., 1991) at the time of treatment (7, 12, 15, or 17 weeks of age) and, in those mice that survived, at the age of 40 weeks. Significant hyperglycemia was considered to be a glucose concentration of 11.1 mM/L or greater because this concentration of blood glucose was 3 standard deviations higher than the mean blood glucose concentration measured in 100 healthy mice (not shown). Histological examination of the islets of the pancreas was done on sections stained with hematoxylin and eosin. The sections were scored independently by two observers who both were unaware of the identity of the groups. The chi square test was used to ascertain the statistical differences between the various treatments.

(iv) T-Cell proliferation assay. Cells of clone C9 and spleen-cell suspensions obtained from female NOD mice were assayed for T-cell proliferation as described previously (Elias et al., 1991). Briefly, 1 x 10^5 clone cells/ml or 1 x 10^6 splenocytes/ml were incubated in quadruplicate for 72 hr in 0.2 ml of culture medium in microtiter wells in the presence or absence of various antigens at 5 µg/ml. Proliferation was measured by the incorporation of [3H]-thymidine into DNA during the final 12 hr of incubation. The results were computed as the stimulation index: the ratio of the mean test cpm in the presence of antigen to the mean background cpm in the absence of antigen. Standard deviations between quadruplicates were always <10% of the mean cpm. The background was <1000 cpm in splenocyte experiments and <200 cpm with C9 cells. The spleen of each mouse was tested separately. Results of each group of mice are shown as the mean ±SD.

EXAMPLE 1

Treatment of NOD mice with p277 or fragments thereof

[0041] To test whether either of the two 12-amino acid halves of the p277 peptide, alone or combined, are effective in NOD mice as is p277, female NOD mice were treated at the age of 7 weeks by subcutaneous inoculation of 50 µg of various peptides in oil. The status of the mice by 40 weeks of age was determined.

[0042] The results are shown in Table 1. It can be seen that the control hsp60 peptide p278 had no effect on development of disease: of the 40 mice treated, all were diabetic and 90% were dead by 40 weeks of age. In contrast, the p277 peptide completely prevented death and cured 60% of the 20 treated mice. The fragments of p277 were less effective: the amino half of p277 (p277.N), the carboxy half of p277 (p277.C) and a mixture of both (p277.N, p277.C)
worked about half as well as did the intact p277. Peptide p277.C was synthesized attached to peptide p278 to produce a longer peptide; however, p277.C-p278 was not any better than p277.C alone. Therefore, it can be concluded that the full therapeutic effect requires the intact p277 peptide.

**EXAMPLE 2**

**Treatment of NOD mice with p277 substitution peptides**

[0043] The following peptides were tested in NOD mice: p277, p277 (bridged Cys-Cys), p277(Val⁶-Val¹¹) and p277 (Ser⁶-Ser¹¹).

[0044] NOD females were treated with 100 µg of peptide in a 0.2 cc emulsion of mineral oil (IFA) administered subcutaneously. Mice were treated at 12 weeks of age and the incidence of diabetes was performed at 30 weeks.

[0045] As shown in Table 2, p277(Val⁶-Val¹¹) was as effective as p277 in treatment of diabetes, the incidence of diabetes in untreated mice being 80%, while p277 and p277(Val⁶-Val¹¹) treated mice show an incidence of 22% and 23%, respectively. On the other hand, neither p277(bridged Cys-Cys) nor p277(Ser⁶-Ser¹¹) had any therapeutic effect. Two additional variants of p277, in which the cysteine residues at position 6 and 11 were replaced by alanine or γ-aminobutyric acid residues, were also not effective when tested in vitro both on the clone C9 cells and on NOD splenic T-cells. As these two peptides were not recognized by anti-p277 specific T cells (not shown), they were not further tested in vivo for therapeutic effect.

**EXAMPLE 3**

**Stability of p277 (Val⁶-Val¹¹)**

[0046] Since the reason for replacing the cysteines was the problematic stability of the p277 peptide, the stability of the p277(Val⁶-Val¹¹) was tested at several time points after its synthesis. The p277 peptide is unstable and deteriorates even under strict conditions (lyophilized powder in vacuum, -20°C).

[0047] In order to compare the stability of p277 with its p277(Val⁶-Val¹¹) analog, both peptides were synthesized at the same time and stored as dry powder at -20°C. At 1, 9 and 20 weeks after the date of synthesis, an aliquot was weighed, dissolved and tested. The readout for the stability of the peptide was its ability to stimulate the T cell clone C9. Fig. 1 demonstrates the results of the experiment. It can be seen that, while the native p277 lost most of its effect within 9 weeks and all of it by 20 weeks after synthesis, p277(Val⁶-Val¹¹) was unchanged after 20 weeks of storage.
As it is believed that the instability of p277 is caused by the cysteine residues, it is expected that any of the analogs of the present invention which retain the biological activity of p277 will have an improved stability over p277 in a manner similar to that demonstrated in this example for p277(Val6-Val11).

**EXAMPLE 4**

Treatment of NOD female mice with p277 or p277 (Val6-Val11) reverses insulitis

NOD female mice were treated at 12 weeks of age with 100 µg/mouse of unmodified p277 or p277(Val6-Val11) in 0.1 cc emulsion of mineral oil (incomplete Freund's adjuvant), subcutaneously. Control mice received an emulsion of PBS and mineral oil. At 6 months of age, 5 mice of each group were sacrificed, their pancreas removed and fixed in bouin and sections were stained by hematoxylin:eosin. The insulitis was scored in a blind fashion. Since the control mice developed severe diabetes, they were sacrificed at 5 months of age. By then, the control mice blood glucose levels were in the range of 29-48 mmol/L. The results are shown in Table 3.

**Table 3**

</tbody>
</table>

At 12 weeks of age, the time of treatment, about 60% of the islets in the untreated mice showed intra-islet insulitis, about 20% of the islets had peri-islet insulitis, and about 20% of the islets showed no insulitis. Intra-islet infiltration is considered to be a severe form of insulitis associated with lack of β-cell function. As shown in Table 3, a marked divergence in the appearance of the islets developed in the two treated groups compared to control mice treated with the oil alone. The mice treated with the oil (control) showed a progressive fall in the proportion of unaffected islets and only 10% normal islets could be seen by 22 weeks of age, a time when all of the mice were overtly diabetic. About 67% of the islets showed intra-islet insulitis at 22 weeks and the remaining 23% of the islets showed peri-islet insulitis. In contrast, the mice treated with p277 or with p277(Val6-Val11) showed a rise in the numbers of normal islets (between 25% and 52%) and a fall in the number of islets with intra-islet insulitis (between 6% and 17%). The islets with peri-islet insulitis rose to about 31%-69%. Thus, p277 and p277(Val6-Val11) treatments were associated with an improved histological picture consistent with reversal of the degree of insulitis persisting for over 3 months after treatment.

Additional results using p277 (V) in female NOD mice.

Fifteen additional experiments have been done in which groups of 10 NOD female mice each were treated with p277(V) in oil or with oil alone at the ages of 12-15 weeks. Of the total of 150 mice treated with oil alone, 90% developed diabetes and 85% died by the age of 32 weeks. In contrast, the p277(V) treated mice showed an incidence of diabetes of only 50% (p<0.01) and only 20% died of severe disease (p<0.01). Therefore, late treatment with p277 (V) was effective in arresting the development of lethal diabetes.

**EXAMPLE 5**

Peptide therapy of typeI diabetes using p277(Val6-Val11) in lipid emulsions

Autoimmune destruction of the insulin-producing β-cells in the pancreas is mediated by T-lymphocytes. An inflammatory infiltrate develops around the pancreatic islets at 5-8 weeks of age and β-cell destruction leading to insulin deficiency and overt diabetes becomes manifested at 14-20 weeks of age affecting almost 100% of female NOD mice by 35-40 weeks of age.

NOD female mice were treated with 100 µg of peptide p277(Val6-Val11) per mouse subcutaneously in 0.1 ml of PBS or of a 10% lipid emulsion composed of 10% soybean oil, 1.2% egg phospholipids and 2.25% glycerol (Intralipid, Kabi Pharmacia AB, Sweden).

The incidence of diabetes at 6 months of age and the production of anti-p277(Val6-Val11) antibodies was...
followed. Diabetes was diagnosed as persistent hyperglycemia, blood glucose levels over 11.1 mmol/L measured at least twice at weekly intervals with Beckman Glucose Analyzer II. Successful peptide treatment was assayed by maintenance of a normal blood glucose concentration (less than 11.1 mmol/L), remission of the intra-islet inflammation of the pancreatic islets (insulitis) and induction of antibodies to the therapeutic peptide as an indicator of a TH2-type immune response. The results are shown in Table 4.

* p<0.01 compared to untreated NOD mice

[0055] As can be seen from Table 4, treatment with a peptide of the present invention administered in Intralipid was effective in reducing the incidence of diabetes and death. On the other hand, treatment administered in PBS was ineffective.

EXAMPLE 6

Peptides p277 and p277(Val^6-Val^11) are immunologically cross-reactive

[0056] Cells of the T-cell clone C9 isolated from prediabetic NOD mice were incubated with peptides p277 (closed circles), p277(Val^6-Val^11) (open circles), p277(Ser^6-Ser^11) (closed squares) and p277(bridged Cys-Cys) (open lozenges). The results are shown in Fig. 2. The clone C9 was found to manifest a positive proliferation response only to peptides p277 and p277(Val^6-Val^11). This proves that p277 and p277(Val^6-Val^11) are cross-reactive and that the peptides p277(Ser^6-Ser^11) and p277(bridged Cys-Cys), which are not effective therapeutically, are not immunologically cross-reactive.

EXAMPLE 7

Newly diagnosed IDDM patients show T-cell proliferative responses to both p277 and p277(Val^6-Val^11)

[0057] Newly diagnosed (2-4 weeks) IDDM patients were tested in a proliferation assay. Peripheral blood lymphocytes were isolated from whole heparinized blood on ficoll-hypaque, and screened *in vitro* for proliferation, measured as 3H-thymidine incorporation, induced by hsp60 peptides p277, p277(Val^6-Val^11) and control peptide p278. The T cell proliferative response is depicted as stimulation index (SI): the ratio between peptide-stimulated thymidine incorporation and background (no antigen added) thymidine incorporation by the T cells.

<td>2.5</td>
</tr>
</tbody>
</table>

[0058] As shown in Table 5, newly diagnosed IDDM patients respond to p277 (Val^6-Val^11) as well as to the p277 peptide. Therefore, p277(Val^6-Val^11) is immunologically equivalent to p277. Since the therapeutic effect of p277 is mediated by immunological recognition, the fact that p277(Val^6-Val^11) is immunologically cross-reactive with p277, indicates it can be used instead of p277 in treating diabetes.
EXAMPLE 8

T-cell responses to hsp60 and peptide in IDDM and healthy individuals

[0059] Twenty one IDDM patients and fourteen healthy blood-donors were screened for anti-hsp60 and p277(V) by means of the proliferation assay of Example 7. Tables 6 and 7 show the proliferative T cell response (stimulation index; SI) of each individual to control antigen (control Ag), i.e., tetanus toxoid and influenza virus - Texas strain, to whole recombinant hsp60 and to p277(V). SI values of 3 or greater were considered to be positive.

Table 8 is a summary table showing that 86% and 52% of the patients responded to hsp60 and to p277(V) compared to 21% and 14% of the controls (p<0.05). Thus, the IDDM group was significantly positive for T cell responses to hsp60 and p277(V). This leads to the conclusion that the incidence of hsp60 and p277(V) reactive individuals is higher among IDDM patients than among healthy people.

EXAMPLE 9

NOD T-cell proliferation to p277(Lys¹⁹)

The p277(Lys¹⁹) peptide differs from p277 by one amino-acid. In order to confirm that p277(Lys¹⁹) is an autoantigen in NOD IDDM, we compared T-cell proliferation to peptide p277 and to peptide p277(Lys¹⁹). Fig. 3 demonstrates that T cells of female NOD spleens proliferated to the p277(Lys¹⁹) peptide to the same extent as to p277. There was no response to the control peptide p278.

The above results were confirmed using clone C9, a diabetogenic NOD T-cell clone that was found to respond to the human peptide p277 (Elias et al., 1991). C9 cells were found to proliferate to the p277(Lys¹⁹) peptide to the same extent as to the p277 peptide (Fig. 4).

EXAMPLE 10

Treatment of NOD female mice with p277 (Lys¹⁹)

The present inventors have previously reported that advanced insulitis present in 3 month old female NOD mice could be arrested by treating the mice with a single injection of human p277; the treated mice developed a lower incidence of clinically overt diabetes and death from severe hyperglycemia. To test whether the peptide p277(Lys¹⁹), that is the self mouse p277 peptide, was also effective, we treated 3 month old female NOD mice with 100 µg of either human p277 or p277(Lys¹⁹) in IFA.

Peptides p277 or p277(Lys¹⁹) at a concentration of 2 mg/ml in phosphate buffered saline (PBS) were emulsified with an equal volume of incomplete Freund's adjuvant (IFA). Groups of 10 female 3-month old NOD mice were injected subcutaneously with 0.1 ml (100 µg peptide) of emulsion containing either peptide. Control mice were injected with an emulsion of PBS and IFA. Mice were bled every 4 weeks and blood glucose levels were determined with Beckmann Glucose Analyser II. The incidence of hyperglycemia and death from diabetes was scored at 6 months of age. Mice were considered diabetic if their blood glucose was greater than 11 mmol/L.

The results are shown in Table 9. At 6 months of age, 90% of the control mice were overtly hyperglycemic.
and 60% had died of diabetes. In contrast, treatment with either p277 or p277(Lys19) prevented both diabetes (40% and 50% incidence, respectively) and death (10% and 20% incidence, respectively). Thus, the mouse self peptide p277 (Lys19) seems to be as effective as the foreign p277 in the therapy of advanced insulitis.

*p < 0.05

[0066] These results show that the proliferative responses of NOD T cells detected using the human hsp60 molecule and its p277 peptide are the equivalent of an autoimmune response to mouse hsp60 and to the mouse p277(Lys19) sequence. This was demonstrated for the diabetogenic C9 T cell clone as well as for the spontaneous response developing in the spleens of pre-diabetic mice. Moreover, p277(Lys19) was as effective as p277 in the treatment of diabetes in NOD mice. Spleen T cells of age and sex matched mice of other strains did not manifest a spontaneous T-cell proliferative response to p277 (not shown).

[0067] The finding of autoimmunity to a mouse hsp60 sequence targeted by diabetogenic T cells supports the general belief that IDDM is caused by an autoimmune process.

### EXAMPLE 11

#### Treatment of STZ-induced diabetes by p277(V)

[0068] Streptozotocin (STZ) is a beta-cell specific toxin which can cause toxic diabetes by destroying the beta-cells within 24-48 h if one dose of 200 mg/kg is injected. Given in small subtoxic doses it induces in genetically susceptible mice insulitis leading to diabetes. The inflammatory process can take 20-30 days, depending on the dose of STZ. The regular protocol for STZ-induced diabetes is a dose of 200 mg STZ per kg body weight, given in 5 equal doses of 40 mg/kg on consecutive days (Like and Rossini, 1976) and the model is called low-dose STZ. We found that if the total dose is reduced to 150 mg/kg (30 mg/Kg x 5), diabetes develops within 80-100 days. This slowly progressing form of STZ-induced diabetes probably better resembles the autoimmune diabetes in humans and is of the same duration as the preclinical stage of the spontaneous diabetes in NOD mice (Castano and Eisenbarth, 1990). Moreover, the acute toxic effects are diminished as the dose is reduced.

[0069] The 60 kDa heat shock protein (hsp60) plays a role in both NOD (Elias et al., 1990) and STZ-induced (Elias et al., 1994) diabetes. We have previously shown that both antibody and T cell proliferative responses to hsp60 occur before the onset of overt diabetes. T cell clones specific to hsp60 were derived from prediabetic NOD mice and could adoptively transfer insulitis and hyperglycemia in young NOD (Elias et al., 1991)) or τγ δ NOD mice. The NOD diabetogenic T cell clones recognize a 24 amino acid long peptide of the hsp60 sequence 437-460 we call p277. STZ-induced diabetes is also accompanied by anti-p277 T cell responses at the preclinical stage.

[0070] Previous examples have shown that the p277 (Val6-Val11) peptide protects NOD mice. The present experiment tests the efficacy of p277(V) treatment in the low dose STZ model.

[0071] Male mice, 10 per group, were treated with a dose of STZ 30 mg/kg, daily for 5 days. One week later, the mice were treated with 100 µg of either p277(V) in oil, a peptide of glutamic acid decarboxylase (GADp34) described by Kaufman et al, 1993, as being involved in the diabetes of NOD mice, or oil alone. The treatment was repeated on day 85. On day 100, the mice were bled and their blood tested for hyperglycemia (glucose concentration greater than 15 nmol/L). The results are summarized in Fig. 5. It can be seen that the mean blood glucose of the groups of mice treated with GADp34 or untreated were in the hyperglycemic range. In contrast, the mean blood glucose of the mice treated with p277(V) was in the normal range. Thus, p277(V) can be effective in treating diabetes induced in male C57BL/ksj mice by STZ as well as the spontaneous diabetes developing in the genetically disparate female NOD mice. The applicability of p277(V) therapy is not limited to diabetes of only one cause or to only one genotype or gender.

(ii) MOLECULE TYPE: peptide
(xii) SEQUENCE DESCRIPTION: SEQ ID NO: 10:

Asn Glu Asp Gln Lys Ile Gly Ile Glu Ile Ile Lys Arg Thr Leu Lys  
Ile

Claims

1. A peptide of the sequence I:

Val-Leu-Gly-Gly-Gly-X₁-Ala-Leu-Leu-Arg-X₂-Ile-Pro-

6 11

Val-Leu-Gly-Gly-Gly-X₁-Ala-Leu-Leu-Arg-X₂-Ile-Pro-

(I)

19

Ala-Leu-Asp-Ser-Leu-X₃-Pro-Ala-Asn-Glu-Asp (SEQ ID NO: 2)

wherein X₁ and X₂ each is a Cys or Val residue, and X₃ is a Thr or Lys residue, but X₁ and X₂ cannot both be Cys residues when X₃ is Thr, and salts and functional derivatives thereof.

2. A peptide according to claim 1 selected from the peptides herein designated p277(Val⁶) wherein X₁ is Val, X₂ is Cys and X₃ is Thr; p277(Val¹¹) wherein X₁ is Cys, X₂ is Val and X₃ is Thr; p277 (Val⁶-Val¹¹) wherein both X₁ and X₂ are Val and X₃ is Thr; p277 (Lys¹⁹) wherein both X₁ and X₂ are Cys and X₃ is Lys; p277 (Val⁶-Lys¹⁹) wherein X₁ is Val, X₂ is Cys and X₃ is Lys; p277(Val¹¹-Lys¹⁹) wherein X₁ is Cys, X₂ is Val and X₃ is Lys; p277(Val⁶,¹¹-Lys¹⁹) wherein both X₁ and X₂ are Val and X₃ is Lys.

3. Use of a peptide according to claim 1 or 2 for the preparation of a composition for diagnosis of insulin-dependent diabetes mellitus (hereinafter IDDM).

4. A method for diagnosing the presence or incipience of IDDM in a patient, comprising testing the blood or urine of said patient with a peptide according to claim 1 or 2 as antigen for the presence of antibodies or T cells which are immunologically reactive with human hsp60, whereby a result indicating the positive presence of anti-hsp60 antibodies or of a T cell which immunoreacts with hsp60 indicates a high probability of the presence or incipience of IDDM.
5. A method according to claim 4, wherein the presence of anti-hsp60 antibodies is tested by radioimmunoassay or by an ELISA test.

6. A kit for diagnosing the presence of IDDM by testing for the presence of anti-hsp60 antibodies, according to the method of claim 4 or 5, comprising:

(i) an antigen being a peptide of sequence (I) in claim 1; and
(ii) a tagged antibody capable of recognizing the non-variable region of said anti-hsp60 antibodies to be detected.

7. A method according to claim 4, wherein the presence of a T cell which immunoreacts with hsp60 is tested by a T cell proliferation test comprising the following steps:

(i) preparing a mononuclear cell fraction containing T cells from a blood sample obtained from said patient;
(ii) adding to said mononuclear cell fraction an antigen selected from a peptide according to claim 1;
(iii) incubating said cell fraction in the presence of said antigen for a suitable period of time and under suitable culture conditions;
(iv) adding a labeled nucleotide to the incubated cell culture of (iii) at a suitable time before the end of said incubation period to provide for the incorporation of said labeled nucleotide into the DNA of proliferating T cells; and
(v) determining the amount of proliferating T cells by analysis of the amount of labeled nucleotide incorporated into said T cells.

8. A method according to claim 4, wherein the presence of a T cell which immunoreacts with hsp60 is tested by a T cell cytokine response test comprising the following steps:

(i) preparing a mononuclear cell fraction containing T cells from a blood sample obtained from said patient;
(ii) adding to said mononuclear cell fraction an antigen selected from a peptide according to claim 1;
(iii) incubating said cell fraction in the presence of said antigen for a suitable period of time and under suitable culture conditions; and
(iv) measuring the presence of cytokine secreted by the responding lymphocytes into the medium; wherein the cytokine is IFN-γ, IL-2, IL-4, IL-6, IL-10, TNF-α or TGFβ.

9. A kit for diagnosing the presence of IDDM by testing for the presence of a T cell which immunoreacts with hsp60 according to the method of claim 7, comprising:

(i) an antigen being a peptide according to claim 1;
(ii) a labeled nucleotide; and
(iii) a suitable medium for culture of lymphocytes.

10. A kit for diagnosing the presence of IDDM by testing for the presence of a T cell which immunoreacts with hsp60 according to the method of claim 8, comprising:

(i) an antigen being a peptide according to claim 1;
(ii) a suitable medium for culture of lymphocytes; and
(iii) an assay kit for measuring the presence of the cytokine secreted by the responding lymphocytes into the medium.

11. A preparation for preventing or treating IDDM, comprising a T cell product selected from the group consisting of: (a) human T cells which manifest specificity for the p277 sequence of human hsp60, which cells have been activated by incubating in the presence of a peptide of sequence I according to claim 1; (b) said human T cells of (a) which have been irradiated or otherwise attenuated; and (c) said human T cells of (a) which have been subjected to pressure treatment by means of hydrostatic pressure, treatment with chemical cross-linking agent and/or treatment with a cytoskeletal cross-linking agent.

12. A preparation according to claim 11, wherein said human T cells of (a) are autologous T cells obtained from the IDDM patient to be treated, and said specificity of said T cells has been developed by in vitro contact with said peptide of sequence I.
13. A preparation according to claim 11 or 12, wherein said T cells have developed \textit{in vitro} specificity to a peptide of sequence I according to claim 1.

14. A pharmaceutical composition comprising a peptide of sequence I according to claim 1 and a pharmaceutically acceptable carrier.

15. A pharmaceutical composition according to claim 14 for the prevention or treatment of IDDM.

16. A pharmaceutical composition according to claim 14 or 15, wherein said peptide is a peptide according to claim 2.

17. Use of a peptide according to claim 1 or 2 for the preparation of a pharmaceutical composition for the prevention or treatment of IDDM.

**Patentansprüche**

1. Peptid der Sequenz I:

\[
\text{Val-Leu-Gly-Gly-Gly-X}_1\text{-Ala-Leu-Leu-Arg-X}_2\text{-Ile-Pro-}
\]

(SEQ ID NO: 2)

wobei X1 und X2 jeweils ein Cys- oder Val-Rest und X3 ein Thr- oder Lys-Rest sind, jedoch X1 und X2 nicht beide Cys-Reste sein können, wenn X3 Thr ist, und Salze und funktionelle Derivate davon.

2. Peptid nach Anspruch 1 ausgewählt aus den Peptiden, die hierin bezeichnet sind als p277 (Val6), wobei X1 Val, X2 Cys und X3 Thr ist; p277 (Val11), wobei X1 Cys, X2 Val und X3 Thr ist; p277 (Val6-Val11), wobei sowohl X1 als auch X2 Val sind und X3 Thr ist; p277 (Lys19), wobei sowohl X1 als auch X2 Cys sind und X3 Lys ist; p277 (Val6-Val11-Lys19), wobei sowohl X1 Val, X2 Cys und X3 Lys ist; p277 (Val11-Lys19), wobei X1 Cys, X2 Val und X3 Lys ist; p277 (Val6-11-Lys19), wobei sowohl X1 als auch X2 Val sind und X3 Lys ist.

3. Verwendung eines Peptids nach Anspruch 1 oder 2 für die Herstellung einer Zusammensetzung zur Diagnose von insulinabhängigem Diabetes mellitus (im Folgenden IDDM genannt).

5. Verfahren nach Anspruch 4, wobei die Anwesenheit von anti-hsp60-Antikörpern durch einen Radioimmuntest oder durch einen ELISA-Test getestet wird.

6. Kit zur Diagnose der Anwesenheit von IDDM durch Testen der Anwesenheit von anti-hsp60-Antikörpern nach dem Verfahren von Anspruch 4 oder 5, umfassend:

(i) ein Antigen, das ein Peptid der Sequenz (I) in Anspruch 1 ist; und
(ii) einen markierten Antikörper, der fähig ist, die nicht-variable Region der nachzuweisenden anti-hsp60-Antikörper zu erkennen.

7. Verfahren nach Anspruch 4, wobei die Anwesenheit einer T-Zelle, die mit hsp60 immunreagiert, durch einen T-Zellen-Wachstumstest getestet wird.
wobei das Verfahren die folgenden Schritte umfasst:

(i) Herstellen einer mononucleären Zellfraktion, die T-Zellen von einer von dem Patienten erhaltenen Blutprobe enthält;
(ii) Hinzufügen eines Antigens, das von einem Peptid nach Anspruch 1 ausgewählt ist, zu der mononucleären Zellfraktion;
(iii) Inkubieren dieser Zellfraktion in Anwesenheit des Antigens über einen geeigneten Zeitraum unter geeigneten Kultivierungsbedingungen;
(iv) Hinzufügen eines markierten Nucleotids zu der inkubierten Zellkultur von (iii) zu einer geeigneten Zeit vor Ende der Inkubationszeit, um den Einbau des markierten Nucleotids in die DNA der proliferierenden T-Zellen zu ermöglichen; und
(v) Bestimmen der Menge von proliferierenden T-Zellen durch Analyse der Menge von markiertem Nucleotid, das in die T-Zellen eingebaut ist.

(i) Herstellen einer mononucleären Zellfraktion, die T-Zellen von einer von dem Patienten erhaltenen Blutprobe enthält;
(ii) Hinzufügen eines Antigens, das von einem Peptid nach Anspruch 1 ausgewählt ist, zu der mononucleären Zellfraktion;
(iii) Inkubieren dieser Zellfraktion in Anwesenheit des Antigens über einen geeigneten Zeitraum unter geeigneten Kultivierungsbedingungen;
(iv) Hinzufügen eines markierten Nucleotids zu der inkubierten Zellkultur von (iii) zu einer geeigneten Zeit vor Ende der Inkubationszeit, um den Einbau des markierten Nucleotids in die DNA der proliferierenden T-Zellen zu ermöglichen; und
(v) Bestimmen der Menge von proliferierenden T-Zellen durch Analyse der Menge von markiertem Nucleotid, das in die T-Zellen eingebaut ist.

8. Verfahren nach Anspruch 4, wobei die Anwesenheit einer T-Zelle, die mit hsp60 immunreagiert, durch einen T-Zell-Cytokinantworttest bestimmt wird, wobei das Verfahren die folgenden Schritte umfasst:

(i) Herstellen einer mononucleären Zellfraktion, die T-Zellen von einer von dem Patienten erhaltenen Blutprobe enthält;
(ii) Hinzufügen eines Antigens, das von einem Peptid nach Anspruch 1 ausgewählt ist, zu der mononucleären Zellfraktion;
(iii) Inkubieren dieser Zellfraktion in Anwesenheit des Antigens über einen geeigneten Zeitraum unter geeigneten Kultivierungsbedingungen;
(iv) Messen der Anwesenheit von durch die antwortenden Lymphocyten in das Medium abgegebenem Cytokin, wobei das Cytokin IFN-γ, IL-2, IL-4, IL-6, IL-10, TNF-α oder TGFβ ist.

9. Kit zur Diagnose der Anwesenheit von IDDM durch Testen der Anwesenheit einer T-Zelle, die mit hsp60 immunreagiert, nach dem Verfahren von Anspruch 7, umfassend:

(i) ein Antigen, das ein Peptid nach Anspruch 1 ist;
(ii) ein markiertes Nucleotid; und
(iii) ein geeignetes Medium zur Züchtung von Lymphocyten.

10. Kit zur Diagnose der Anwesenheit von IDDM durch Testen der Anwesenheit einer T-Zelle, die mit hsp60 immunreagiert, nach dem Verfahren von Anspruch 8, umfassend:

(i) ein Antigen, das ein Peptid nach Anspruch 1 ist;
(ii) ein geeignetes Medium zur Züchtung von Lymphocyten; und
(iii) ein Testkit zur Messung der Anwesenheit des Cytokins, das durch die antwortenden Lymphocyten in dem Medium sekretiert wird.

11. Zubereitung zur Vorbeugung oder Behandlung von IDDM, umfassend ein T-Zellprodukt, das ausgewählt ist aus der Gruppe bestehend aus: (a) menschlichen T-Zellen, die Spezifität für die p277-Sequenz von menschlichem hsp60 zeigen, wobei die Zellen durch Inkubation in Anwesenheit eines Peptids der Sequenz I nach Anspruch 1 aktiviert wurden; (b) den menschlichen T-Zellen nach (a), die bestrahlt oder auf andere Weise abgeschwächt wurden; und (c) den menschlichen T-Zellen nach (a), die einer Druckbehandlung mittels hydrostatischen Druck, Behandlung mit einem chemischen Vernetzungsmittel und/oder Behandlung mit einem Cytoskelett-Vernetzungsmittel unterzogen wurden.

14. Arzneimittel, das ein Peptid der Sequenz 1 nach Anspruch 1 und einen pharmazeutisch verträglichen Träger um-
fasst.

15. Arzneimittel nach Anspruch 14 zur Vorbeugung oder Behandlung von IDDM.

16. Arzneimittel nach Anspruch 14 oder 15, wobei das Peptid ein Peptid nach Anspruch 2 ist.

17. Verwendung eines Peptids nach Anspruch 1 oder 2 für die Herstellung eines Arzneimittels zur Vorbeugung oder Behandlung von IDDM.

Reverdikations

1. Un peptide de la séquence I:

\[
\text{Val-Leu-Gly-Gly-Gly-X}_1 - \text{Ala-Leu-Leu-Arg-X}_2 - \text{Ile-Pro-}\
\]

\[
\text{Ala-Leu-Asp-Ser-Leu-X}_3 - \text{Pro-Ala-Asn-Glu-Asp} \quad (\text{SEQ ID NO:2})
\]

dans lequel X1 et X2 sont chacun des résidus du Cys ou du Val, et X3 est un résidu du Thr ou du Lys, mais X1 et X2 ne peuvent pas être tous les deux des résidus du Cys quand X3 est Thr, et des sels et des dérivés fonctionnels de ceux-là.

2. Un peptide selon la revendication 1 sélectionné des peptides désignés ci-dedans comme p277(Val6) dans lequel X1 est Val, X2 est Cys et X3 est Thr; p277(Val11) dans lequel X1 est Cys, X2 est Val et X3 est Thr; p277 (Val6-Val11) dans lequel X1 et X2 sont tous les deux Val et X3 est Thr; p277(Lys19) dans lequel X1 et X2 sont tous les deux Cys et X3 est Lys; p277(Va6-Lys19) dans lequel X1 est Val, X2 est Cys et X3 est Lys; p277 (Val11-Lys19) dans lequel X1 est Cys, X2 est Val et X3 est Lys; p277 (Val6,11-Lys19) dans lequel X1 et X2 sont tous les deux Val et X3 est Lys.

3. L'utilisation d'un peptide selon la revendication 1 ou 2 pour la préparation d'une composition pour le diagnostic du diabète (diabetes mellitus) dépendant de l'insuline (ci-après IDDM).

4. Une méthode pour diagnostiquer la présence ou le début du IDDM chez un patient, comprenant l'analyse du sang ou de l'urine dudit patient avec un peptide selon la revendication 1 ou 2 comme antigène contre la présence des anticorps ou des cellules T qui sont immunologiquement réactives avec l'hsp60 humain, d'où il s'ensuit qu'un résultat indiquant la présence positive des anticorps anti-hsp60 ou d'une cellules T qui immunoréagisse avec l'hsp60 indique une grande probabilité de la présence ou du début de l'IDDM.

5. Une méthode selon la revendication 4, dans laquelle la présence des anticorps anti-hsp60 est testée par radioimmunoessai ou par le test ELISA.

6. Un kit pour diagnostiquer la présence de l'IDDM en testant la présence des anticorps anti-hsp60, selon la méthode de la revendication 4 ou 5, comprenant:

(i) un antigène étant un peptide de la séquence (I) selon la revendication 1; et

(ii) un anticorps marqué capable de reconnaître la région non-variable desdits anticorps anti-hsp60 à détecter.

7. Une méthode selon la revendication 4, dans laquelle la présence d'une cellule T qui immunoréagisse avec l'hsp60 est analysée par un test de prolifération de cellules T comprenant les étapes suivantes:

(i) préparer une fraction de cellules mononucléaires contenant des cellules T d'un échantillon de sang obtenu dudit patient;
(ii) ajouter à ladite fraction de cellules mononucléaires un antigène sélectionné parmi les peptides selon la revendication 1;

(iii) incuber ladite fraction de cellules en présence dudit antigène pendant une période de temps appropriée et sous des conditions de culture appropriées.

(iv) ajouter un nucléotide marqué à la culture incubée de cellules du (iii) à un moment approprié avant la fin de ladite période d'incubation, afin de permettre que ledit nucléotide marqué soit incorporé dans l'ADN des cellules T proliférantes; et

(v) déterminer la quantité de cellules T en prolifération par analyse de la quantité de nucléotides marqués incorporés dans lesdites cellules T.

8. Une méthode selon la revendication 4, dans laquelle la présence d'une cellule T, qui immunoréagisse avec l'hsp60, est analysée par un test de réponse aux cytokines des cellules T comprenant les étapes suivantes:

(i) préparer une fraction de cellules mononucléaires contenant des cellules T d'un échantillon de sang obtenu dudit patient;

(ii) ajouter à ladite fraction de cellules mononucléaires un antigène sélectionné parmi les peptides selon la revendication 1;

(iii) incuber ladite fraction de cellules en présence dudit antigène pendant une période de temps appropriée et sous des conditions de culture appropriées ; et

(iv) mesurer la présence de cytokine secretée par les lymphocytes qui repondent dans le milieu ; dans laquelle la cytokine est IFN-γ, IL-2, IL-4, IL-6, IL-10, TNF-α ou TGFB.

9. Un kit pour diagnostiquer la présence du IDDM en recherchant la présence d'une cellule T qui immunoréagisse avec l'hsp60, selon la méthode de la revendication 7, comprenant:

(i) un antigène qui est un peptide selon la revendication 1;

(ii) un nucléotide marqué et

(iii) un milieu approprié pour la culture des lymphocytes.

10. Un kit pour diagnostiquer la présence de IDDM par l'analyse de la présence d' une cellule T qui immunoréagisse avec l'hsp60 selon la méthode de la revendication 8, comprenant:

(i) un antigène qui est un peptide selon la revendication 1;

(ii) un milieu approprié pour la culture de lymphocytes; et

(iii) un kit d'analyse pour mesurer la présence de la cytokine secretée dans le milieu par les lymphocytes qui répondent.

11. Une préparation pour prévenir ou pour traiter l'IDDM, comprenant un produit de cellules T qui est-sélectionné dans le groupe consistant de: (a) cellules T humaines qui manifestent une spécificité pour la séquence p277 de l'hsp60 humain, ces cellules ayant été activées par l'incubation en présence d'un peptide de séquence I selon la revendication 1; (b) lesdites cellules T humaines selon (a) qui ont été irradieées ou atténuées d'une autre manière; et (c) lesdites cellules T humaines selon (a) qui ont subies un traitement sous pression par le moyen d'une pression hydrostatique, un traitement avec un agent de réticulation chimique et/ou un traitement avec un agent de réticulation cytoskeletal.

12. Une préparation selon la revendication 11, dans laquelle lesdites cellules T humaines du (a) sont des cellules T autologues qui sont obtenues du patient atteint d' IDMM à traiter, et ladite, spécificité desdites cellules T a été développée par un contact in vitro avec ledit peptide se la séquence I.
13. Une préparation selon la revendication 11 ou 12, dans laquelle lesdites cellules T ont développé une spécificité
in vitro à un peptide de la séquence I selon la revendication 1.

14. Une composition pharmaceutique comprenant un peptide de la séquence I selon la revendication 1 et un support
qui est acceptable pharmaceutiquement.

15. Une composition pharmaceutique selon la revendication 14 pour la prévention ou le traitement de IDDM.

16. Une composition pharmaceutique selon la revendication 14 ou 15, dans laquelle ledit peptide est un peptide selon
la revendication 2.

17. L'utilisation d'un peptide selon la revendication 1 ou 2 pour la préparation d'une composition pharmaceutique pour
la prévention ou le traitement de IDDM.
