Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

[0001] The present invention relates to a digital multimedia device such as a digital video device and an arrangement and method which allows the device to communicate with another device on a common bus.

[0002] In the field of digital video processing, it is known to code digital video signals such that special processing is needed in the receiver to be able to reproduce the video signals. In particular, it has been proposed to provide a Conditional Access Module which can perform all of the descrambling and other conditional access functions of the digital TV receiver. This allows conditional access and signal decoding functions to be separated from a host receiver, such that a generic digital TV receiver can operate with many different conditional access systems in different Conditional Access Modules.

[0003] To allow communication between a Conditional Access Module and a digital TV receiver, a Common Interface has been proposed and standardized by CENELEC (EN50221 Common Interface Specification for Conditional Access and other Digital Video Broadcasting Decoder Applications). This standard Common Interface defines a transport stream interface in which various virtual channels are time multiplexed and a Command Interface over which various additional command data are sent. The Common Interface thus allows connection of a Conditional Access Module to a digital TV receiver or indeed any other digital video device.

[0004] As a basis for the present invention, it is now recognised that it would be advantageous to provide a Conditional Access Module on a local network of digital multi-media devices including audio and video devices, such that the various functions available in the Conditional Access Module can be provided to all of the devices on the network.

[0005] A standard has been proposed for connecting together various digital video devices on a local network. In particular, IEEE 1394 is a 1995 IEEE standard for a high performance serial bus and defines a bus, which will be referred to as an IEEE 1394 Serial Bus, for connecting together various digital consumer audio/visual products.

[0006] The IEEE 1394 specification defines a physical connector, electrical signalling and a set of link and transport protocols allowing the serial bus to self configure and carry audio, video and control information efficiently.

[0007] A further set of additional protocols have also been defined to carry MPEG data and provide control mechanisms between different items of equipment on the IEEE 1394 Serial Bus. These protocols are defined in the specification "Digital Interface for Consumer Electronic Audio/Video Equipment" (IEC 1883).

[0008] The IEEE 1394 specification defines mechanisms and protocols to carry two types of data, namely asynchronous and isochronous data.

[0009] Asynchronous data generally has no requirements on the transport mechanism regarding time, for example the jitter imposed or the delay in transmission. This data can be used for instance for file data or general command and status data.

[0010] On the other hand, isochronous data has strong requirements for low jitter and a fixed or bounded delay for transmission and may be used for MPEG coded audio and video data.

[0011] In view of the developments with the IEEE 1394 Serial Bus, it is now considered to connect a Conditional Access Module to a number of different digital multi-media devices such as audio and/or video devices using the IEEE 1394 Serial Bus. Unfortunately, however there are significant problems in implementing such a system. IEEE 1394 related protocols have been developed that are intended for use with streams of single channel MPEG data and its own protocols are provided for various command data. In particular, the Conditional Access Common Interface and the IEEE 1394 serial bus have set different standards.

[0012] Banks D et al.: "Breaking open the set top box" Proceedings of the SPIE, SPIE, Bellingham, VA, US, vol. 3228, 4 November 1997 (1997-11-04), pages 105-116, EP002064906 ISSN: 0277-786X considers breaking open a set top box by physically separating the access-network-specific functions from the application-specific functions. An access network gateway is provided for connection to incoming broadcast signals. This allows a transport stream (or part of that stream) to be sent on an IEEE 1394 bus to one or more appliances, such as a PC, a digital TV, or digital VCR, etc. The access network gateway can filter the transport stream packets based on the program identifier (PID) value in the packet header. This allows only the program(s) of interest to be selected for forwarding out onto the IEEE 1394 bus.

[0013] EP-A-0 905 932, relevant under Article 54(3) EPC only, describes the use of an IEEE 1394 bus have connected to it a number of set top boxes and also a number of modules for performing a descrambling process on the data stream output from the set top boxes. In the case where a broadcasting signal is received, the PID filter of the set top box extracts only the packet for the desired program from the transport stream output from the demodulator by referring to a PID and only the packet for the desired programme is sent out from the digital interface of the set top box.

[0014] A first aspect of the present invention concerns the problem that, for the Common Interface, the transport stream sent to the Conditional Access Module includes all of the virtual channels and hence takes up a significant amount of the bandwidth available over the IEEE 1394 Serial Bus.

[0015] The first aspect of the present invention also deals with the problem that it is often not sufficient to send to a Conditional Access Module merely the virtual channel which it requires for descrambling, since other data in the transport stream may be required by the Conditional Access Module.

[0016] According to the first aspect of the present in-
vention, there is provided a digital multi-media receiver for use with a Conditional Access Module using a Common Interface comprising:

an output for an IEEE 1394 Serial Bus for transmitting a transport stream to a Conditional Access Module on the bus;
a reader for reading the contents of a transport stream and identifying data which is not required for processing by a Conditional Access Module;
a stripper for stripping out at least some of the identified unrequired data from the transport stream;
a coder for producing appropriate AV/C-CTS commands with headers including appropriate AV/C-CTS opcodes corresponding to transport objects of the Command Interface; and
a transmitter for transmitting, through the output and over an IEEE 1394 Serial Bus, the AV/C-CTS commands produced by the coder and all of the remaining data of the transport stream which has not been stripped; wherein
the receiver is arranged to receive a processed transport stream returned by the Conditional Access Module over the IEEE 1394 Serial Bus, together with AV/C-CTS commands with headers including AV/C-CTS opcodes corresponding to transport objects of the Command Interface; and
the receiver further comprises a decoder for producing appropriate Common Interface objects from the received AV/C-CTS commands.

[0017] According to the first aspect of the present invention, there is also provided a network of digital multi-media devices connected by means of an IEEE 1394 Serial Bus, the network comprising:

a receiver for transmitting a transport stream over the IEEE 1394 Serial Bus using a Common Interface; and
a Conditional Access Module for receiving a transport stream over the IEEE 1394 Serial Bus using the Common Interface; wherein
the receiver includes a reader for reading the contents of a transport stream and identifying data which is not required for processing by the Conditional Access Module;
a stripper for stripping out at least some of the identified unrequired data from the transport stream;
a coder for producing appropriate AV/C-CTS commands with headers including appropriate AV/C-CTS opcodes corresponding to transport objects of the Command Interface; and
a transmitter for transmitting to the Conditional Access Module over the IEEE 1394 Serial Bus the AV/C-CTS commands produced by the coder and all of the remaining data of the transport stream which has not been stripped; wherein:

the Conditional Access Module returns a processed transport stream to the receiver over the IEEE 1394 Serial Bus, together with AV/C-CTS commands with headers including AV/C-CTS opcodes corresponding to transport objects of the Command Interface; and
the receiver is arranged to receive the processed transport stream and AV/C-CTS commands and further comprises a decoder for producing appropriate Common Interface objects from the received AV/C-CTS commands.

[0018] Thus, since the only data to be stripped from the transport stream is that data which is positively identified as not being required by the Conditional Access Module, the stripped transport stream contains all of the data required by the Conditional Access Module.

Furthermore, in practice, the stripper will be stripping out virtual channels containing broadcast program content data. The broadcast program content data takes up the most significant proportion of the bandwidth of the transport stream and, therefore, stripping out this data will have a very significant effect on reducing the overall bandwidth of the transport stream.

[0019] The present invention is applicable to any type of digital multi-media device, including devices handling audio data, video data, other multi-media data or a mixture thereof. It is particularly advantageous for digital video devices handling at least video data.

[0020] Preferably, the transport stream is an MPEG-2 transport stream and is transmitted in isochronous channels under the IEC1883 format.

[0021] A table of program specific information (PSI) is provided in the MPEG transport stream, such that unrequired parts of the transport stream can be identified for stripping.

[0022] The receiver is able to determine which streams to strip out not only from the PSI but also the user state, i.e. which program the user wishes to watch or record, etc. As receivers in general can only display one picture at a time then that is the one to be descrambled and all the others can be ignored.

[0023] The invention will be more clearly understood from the following description, given by way of example only, with reference to the accompanying drawings in which:

Figure 1 illustrates a DVB Common Interface architecture;
Figure 2(a) illustrates a network of digital multi-media devices;
Figure 2(b) illustrates a network of digital devices with a Conditional Access Module;
Figure 3 illustrates an IEEE 1394 protocol stack;

Figure 7 illustrates a DVB Common Interface IEEE 1394 implementation protocol stack;

Figure 8 illustrates a device for implementing a Common Interface Command Interface over an IEEE 1394 Serial Bus;

Figure 9 illustrates a Common Interface configuration using an IEEE 1394 Serial Bus; and

Figure 10 illustrates a DVB Common Interface IEEE 1394 implementation Transport Stream Interface protocol stack; and

Figures 11(a) and (b) illustrate a transport stream and associated table.

[0024] As mentioned above, a standard has already been specified for a Common Interface for a Conditional Access Module. Figure 1 illustrates the architecture of this standard.

[0025] As illustrated, a receiver or host 2 is connected to a Common Interface Module such as a Conditional Access Module 4 by means of the Common Interface 6.

[0026] Other types of Common Interface Module might include RF input front ends for receiving, for instance, satellite transmissions, audio decoders for "Auditel" scene description for the visually impaired, audience metering modules, etc.

[0027] The DVB (Digital Video Broadcast) Common Interface specification currently defines the physical layer of the common interface to conform to the PC card standard as specified by the PCMCIA. In other words, physically the connection forming the Common Interface comprises a 68-way connector with the standard PC card arrangement as used in many personal computers today. However, the DVB Common Interface has been designed with a layered architecture to allow new physical layers (for example the smart card form factor) to be used with the same upper layer protocols. In other words, the processing conducted on either side of the physical connection has been designed such that different physical arrangements can be used for the connection without changing the way in which the standardized processing operates.

[0028] As illustrated in Figure 1, the DVB Common Interface includes two main parts, namely a transport stream interface 8 and a command interface 10.

[0029] The transport interface 8 is used to transfer a transport stream from the receiver or host 2 to the module 4 and back to the receiver 2. In particular, the receiver 2 receives an RF input 12, a particular band is selected using a tuner 14 and this band is demodulated in the demodulator 16. The output of the demodulator 16 comprises a transport stream including time multiplexed virtual channels. These are transmitted over the transport stream interface 8 to a descrambler 18 in the module 4. The descrambler 18 identifies those virtual channels for which it is intended and sends back to the receiver 2, over the transport stream interface 8, a transport stream in which selected virtual channels have been descrambled. In the receiver 2, a demultiplexer 20 selects a required virtual channel and passes MPEG packets relating to that virtual channel to an MPEG decoder 22 which, in turn, outputs an audio/video output 24.

[0030] The second part of the DVB Common Interface is the command interface 10. This provides a high level protocol allowing the host receiver 2 and the module 4 to communicate and, furthermore, for Applications in either the host receiver 2 or module 4 to access Resources across the interface. In particular, standardized codes and data formats are provided for communication over the Command Interface.

[0031] A microprocessor 26 of the host receiver 2 and a microprocessor 28 of the module 4 can communicate using the Command Interface. Furthermore, the overall system may include a MODEM, a graphics generator, etc and the Command Interface can be used to transfer control information to these devices also. As an example, the module 4 may wish to communicate with a remote control centre via a MODEM for details of subscription fees and then control a TV display to indicate messages according to the subscription status. This communication can be achieved by means of the Command Interface 10.

[0032] As mentioned above, it has been proposed to link various digital video devices together using an IEEE 1394 Serial Bus. Figure 2a illustrates a network in which a digital TV receiver 30 is connected to a digital video recorder 32, in turn connected to a digital video disk machine 34, in turn connected to a personal computer 36.

[0033] The IEEE 1394 bus is a serial bus that allows a low cost mechanism to transmit audio, video and control information between equipment. It is very well suited to consumer audio/visual applications and is expected to become widely used for many new digital consumer audio/visual products. It is particularly attractive in that it offers a "plug and play" operation. In other words, an additional device may be connected into the network without any special reconfiguring of the network and protocols are included whereby devices on the network automatically determine what other devices are present.

[0034] The IEEE 1394 Trade Association is an industry grouping that brings together all of the interested industry parties for the IEEE 1394 Serial Bus. This Trade Association has worked to define a set of protocols which offer a set of commands to be carried over the IEEE 1394 Serial Bus in the format of the IEC 1883 Function Control Protocol (FCP) mentioned above. The set of commands are known as Audio/Video Control-Command Transactions (AV/C-CTS) and are specified in the AV/C digital Interface Command Set Document developed by the IEEE 1394 Trade Association (see AV/C Digital Interface Command Set Version 2.0D March 26, 1997 Audio/Video Working Group of the IEEE 1394 Trade Association). The AV/C-CTS provides general set-up and control commands and sets of commands specifically for a digital VCR and tuner. They are encoded using a header and
a payload. The header contains information such as the destination address and the opcode specifying the function of the command. Further operands of the commands are carried in the payload of the command.

[0035] Thus, the communication of data over the IEEE 1394 Serial Bus may be considered as a layered structure, with the protocol stack, formed of the various protocol layers, being illustrated in Figure 3.

[0036] For command information, for instance instructing a video recorder to start replaying a video signal, data is sent as asynchronous data over the IEEE 1394 Serial Bus. This is illustrated in the left hand side of the protocol stack of Figure 3.

[0037] The commands are sent using the AV/C-CTS protocol, with a particular AV/C-CTS command having a header which is specific to its destination unit, for instance a video recorder, and indicating the basic required function, for instance replay of a video tape. In particular, the AV/C-CTS header specifies fields for command type (eg. control, status, inquiry, notify, etc), subunit type and subunit identifier, such that it defines the destination subunit for a command AV/C frame and the source subunit for a response AV/C frame. In this way, the AV/C-CTS works with a command/response scheme with a first subunit sending a command AV/C frame to a second subunit and the second subunit responding back with a response AV/C frame.

[0038] The opcode for the command is also specified in the header so as to indicate the basic function. The payload may be arranged to specify other operands or additional information, for instance indicating that play should occur at a certain speed, such as slow forward, fast forward, fastest forward.

[0039] The protocol layer of the AV/C-CTS has been designed to conform to the protocol layer beneath it, the IEC 1883 Function Control Protocol. This is a particular protocol for addressing a node (a unit on the network) with attached data. Thus, in this case, the IEC 1883 FCP would function to transmit the AV/C-CTS as the attached data.

[0040] AV/C-CTS protocols are a specific command set implementation of FCP. The AV/C-CTS commands are encoded using an FCP frame, the header of which specifies the IEC 1394 node (device) destination and source addresses, frame data length, CRC and other information. In particular, the first four bits of the FCP frame payload make a field which specifies the command set being carried by the FCP frame. The FCP frame header carries a value of "0" in this field to indicate that it is carrying an AV/C-CTS command. Command sets other than AV/C-CTS could be carried by the FCP frame using different values in this field. The rest of the FCP frame payload contains the AV/C header and payload.

[0041] The protocol layers defined in the IEEE 1394 specification include a IEE 1394 transaction layer which handles delivery and acknowledgement data for the data and a IEEE 1394 link layer which provides the various data links to the various units. Finally, the lowest layer is the IEEE 1394 physical layer comprising the physical connections.

[0042] The transaction layer provides a set of services to applications running in devices on the IEEE 1394 bus, in particular for asynchronous data only. These are services such as read and write and enable devices to access other devices on the bus by specifying a node id of the device and address within that node. The services are designed to provide reads and writes and provide acknowledgements back to the requester. The transaction layer also provides "lock" services. These are defined as "atomic" operations, meaning the operations are indivisible in time, so that for instance a "test and set" operation from one device on another does not get interrupted half way through by another device modifying the same location. This is very important for a peer-to-peer bus such as IEEE 1394 where many devices can access each other with equal priority.

[0043] The link layer provides the packetisation of the asynchronous and isochronous data. The link layer also provides cycle control which allows isochronous data to be carried with low latency and bounded jitter.

[0044] The lowest layer is the physical layer (or PHY layer in IEEE 1394 terminology). This provides the low level electrical signalling and encoding of the data bits to be transmitted and received. The PHY layer provides the low-level arbitration between devices on the bus so that only one device is driving the bus at a time. The PHY layer also defines the connector and the required characteristics for the cable media.

[0045] The protocol layers for isochronous data, such as MPEG data, are illustrated on the right hand side of Figure 3.

[0046] The isochronous data is transmitted according to the IEC 1883 protocol layer. This is supported directly by the IEEE 1394 link layer, which sets up the various connections with the IEEE 1394 physical layer. In particular, the IEC 1883 protocol layer sets up an isochronous channel between two devices on the bus.

[0047] The IEEE 1394 specification defines the lower layers for the carriage of isochronous data, these being the physical and link layers as described above. The IEC 1883 protocols provide mechanisms to allow the efficient transport of AV data utilising a Common Isochronous Packet (CIP) header. This allows AV data packets to be split up for transport over the IEEE 1394 bus and also has fields to signal data format (standard or high definition video data, 50 or 60Hz field rate). The IEC 1883 specification also provides the concept of logical channels and plugs for the carriage and connection of AV data between devices on the IEEE 1394 bus.

[0048] In this way, the IEEE 1394 Serial Bus and its related protocols provide a mechanism for audio/video peripherals to communicate command and control information, together with digital audio/video data.

[0049] As a basis for the present invention, it is proposed that a Common Interface Module such as a Conditional Access Module could also be connected to a net-
work of digital video devices using an IEEE 1394 Serial Bus.

[0050] Figure 2b illustrates the network of Figure 2a, but further including a Conditional Access Module 38. This arrangement has a number of significant advantages over using the previously proposed PC card implementation of the DVB Common Interface.

[0051] With the Conditional Access Module provided on the network, the conditional access functions can be used equally by every peripheral. Furthermore, no particular peripheral has to provide power to the Module or has to act as a protocol bridge through which the Module communicates with the rest of the network.

[0052] Since the module on the network need not be closely physically bound to any particular receiver, there is more flexibility in the physical form and positioning of it. In other words, whereas previously a Conditional Access Module might be connected to the back of a receiver or video recorder, a network allows the module to be placed in any convenient position and in any convenient form.

[0053] Finally, even if conditional access functions are embedded in a particular device, such as a receiver, rather than in a separate Conditional Access Module, the network makes it possible for other devices to make use of the embedded conditional access functions.

[0054] Figure 4 illustrates the various protocol layers forming the protocol stack for the Command Interface of a Common Interface as implemented in a PC card format. The various sections of the Common Interface standards document EN50221 mentioned above are also given in this figure.

[0055] At the highest layer, the Application Layer, the various Applications and Resources are provided.

[0056] Below this is the Session Layer. Thus, when a particular device has an application requiring the use of a resource, it sets up a session by means of the Session Layer with another Resource.

[0057] The process utilises each of the layers down to the lowest physical layer. From the lowest physical layer, all the various layers are then utilised up to the Resource of the other device. In other words, the data is transmitted between the resource and application by processing the data down from the application through each layer to the physical layer where it is then processed back up to the resource. The data can then return in a similar way from the resource back to the application.

[0058] In general, lower layers are transparent to the upper layers, such that when an Application requires a session with a Resource, it is not aware of how the Session Layer or lower layers achieve that session.

[0059] The lowest generic layer of the DVB Common Interface is the Generic Transport Layer. This layer provides a set of eleven transport objects that are used to control the creation and deletion of transport connections and carry data over these transport connections.

[0060] Below the Generic Transport Layer, the PC card transport layer actually sets up the transmission of data to be suitable for transmission over the PC Card defined electrical/physical interface. Thus, since lower layers are transparent, it is not important to the Generic Transport Layer how further communication of data takes place. In particular, it is not important to the Generic Transport Layer whether the PC card format is used.

[0061] With reference to Figure 5, a solution is proposed to the problem of providing the Command Interface on the IEEE 1394 Serial Bus.

[0062] This solution is based on sending the command data of the Command Interface by means of asynchronous data on the IEEE 1394 Serial Bus and proposes that the AV/C-CTS protocols be extended to carry the command data.

[0063] As illustrated in Figure 5, the PC card transport layer which previously handles the higher Generic Transport Layer is replaced by a Common Interface IEEE 1394 Specific Transport Layer.

[0064] As mentioned above, the lower layers are transparent to the Generic Transport Layer. Therefore, the Generic Transport Layer and higher layers need not be aware of the different Specific Transport Layer and the functioning of the standard Command Interface is not changed.

[0065] Commands are produced in the Generic Transport Layer in the same way as before. However, these are then handled by the Common Interface IEEE 1394 Specific Transport Layer in accordance with the IEEE 1394 arrangement rather than the PC card arrangement.

[0066] The extended AV/C-CTS protocols provide a mechanism for carrying the command interface protocols. In effect, the AV/C-CTS protocols carry the newly defined Common Interface IEEE 1394 Specific Transport Layer.

[0067] The proposed extensions to the AV/C-CTS protocols are as follows. The eleven objects of the Command Interface are each given an AV/C-CTS opcode, such that there is a separate AV/C-CTS command for each one of the eleven objects of the Command Interface. The object of the Command Interface can then be encoded within the payload of the AV/C-CTS command using a similar syntax as is used in the PC Card Implementation.

[0068] The AV/C-CTS protocol may be extended to cover other peripherals defined as "sub-unit types" and the Conditional Access Module can be defined as a new sub-unit type. In this way, each of the eleven new AV/C-CTS opcodes will be recognised as being intended for a Conditional Access Module, in contrast to opcodes intended for the TV receiver, video recorder, etc.

[0069] In this way, the Command Interface can continue to function in the same way as previously defined for the PC Card Implementation. There is no need for modification of the upper layers or, indeed, any awareness of the means of the lower layer communication. Similarly, communication of the command interface data is achieved using the standards already defined for the IEEE 1394 Serial Bus, such that no modifications are required to these standards.
Thus, it is possible to provide a Conditional Access Module which operates over the IEEE 1394 Serial Bus, merely by providing additional AV/C-CTS opcodes corresponding to transport objects of the Command Interface.

Figure 6 illustrates schematically a device such as a host receiver 2 or Conditional Access Module 4 implementing a Command Interface over an IEEE 1394 Serial Bus.

A microprocessor 26,28 can continue to produce and receive command data in the normal way. However, additional functional blocks, namely a coder 40 and a decoder 42, are provided to convert the data according to the extended AV/C-CTS protocols.

The coder 40 produces appropriate AV/C-CTS commands with headers including appropriate ones of the eleven opcodes corresponding to the eleven objects of the Command Interface. Objects of the Command Interface can then also be included in the payloads of the AV/C-CTS commands using a syntax similar to the PC Card Implementation syntax.

The decoder 42 on the other hand produces appropriate Command Interface objects from the opcodes and payloads of the received AV/C-CTS commands.

A transmitter 44 is provided to transmit the AV/C-CTS commands, for instance under the IEC 1883 protocol, via a port 48.

A receiver 46 receives AV/C-CTS commands from the port 48 and distinguishes appropriate AV/C-CTS commands by identifying ones of the eleven new Common Interface type opcodes as opposed to opcodes used for other units.

Figure 7 illustrates an alternative solution to the problem of communicating Command Interface data over the IEEE 1394 Serial Bus.

In particular, it is proposed to use an isochronous channel to carry the Command Interface data. This has the advantage of being able to guarantee a bandwidth for DVB Common Interface Command Interface data, which is very useful when running applications that require a fast response and low delay, eg. graphics. It is proposed that, upon initialization, two isochronous channels would be created, one running from the host to the module and the other from the module to the host.

By comparing Figures 4 and 7, it will be seen that the implementation transport layer of Figure 7, namely the PC card transport layer, has been replaced by a common interface IEEE 1394 specific transport layer.

Since lower layers are transparent to the Generic Transport Layer, replacement of the PC card transport layer will have no effect on the Generic Transport Layer and the Common Interface IEEE 1394 Specific Transport Layer will merely handle the data of the Generic Transport Layer in a manner suitable for the IEEE 1394 Serial Bus. Thus, when a session is required to communicate Command Interface data between an Application and a Resource, the common interface IEEE 1394 specific transport layer and IEC 1883 implementation link layer operate together to set up two isochronous channels over which the command data may be transmitted.

Figure 8 illustrates schematically a device such as a host receiver 2 or a module 4 with a corresponding microprocessor 26 or 28.

As illustrated, an additional functional block 50 is provided. This communicates with other devices over the IEEE 1394 Serial Bus, for instance by means of the IEC 1883 protocol, to set up isochronous channels. The command data of the Command Interface may then be sent or received over an appropriate channel.

Once the isochronous transmission channels are set up, there is no need for acknowledgements and such like. Therefore, the IEEE 1394 Serial Bus side of the interface need not have a knowledge or require any modification in view of the Command Interface data being transmitted. Preferably, however, this implementation can include features of that discussed above. In particular, the AV/C-CTS protocol may nevertheless be extended so as to define a Conditional Access Module as another sub-unit type in addition to previous units such as the receiver and video recorder. This will allow increased inter-operability with other devices on the IEEE 1394 Serial Bus, in particular allowing the Conditional Access Module to be identified by other peripherals on the IEEE 1394 Serial Bus.

The transport objects of the Command Interface consist of objects used for transport connection creation and deletion and objects used to carry the data for upper protocol layers. The control related objects can be encoded as AV/C-CTS commands, either each in separate AV/C-CTS commands or in one generic AV/C-CTS command.

The objects used for data carriage could then be used to carry the data to and from the module on the isochronous channels.

In other words, the generic transport layer defines eleven objects - these can be separated into two sets. One set is used for connection management, setting up and closing down transport connections. The other set is used for data carriage over an existing transport connection previously set up using the other transport objects. Generally transport connections are set up infrequently and the most heavily used transport objects are those used to carry data.

Use of the isochronous channel guarantees bandwidth for applications. Hence, the transport objects used most on the isochronous channel would be transport objects carrying data; not setting up connections etc. Hence, the connection management transport objects could be still carried as AV/C-CTS commands as previously discussed and it would not affect the efficiency of the scheme much. Since a layered scheme is used, the generic transport layer need not be aware of whether the objects were carried as asynchronous or isochronous data. The connection management transport objects can
be considered to be more suitable to be carried as AV/C-CTS commands.

[0088] On the other hand, all eleven of the transport objects of the command interface could be encoded in the same way as with the current DVB common interface specification and then carried in the IEEE 1394 isochronous channels. This avoids the use of the AV/C command set, since this is only required for use with the asynchronous data.

[0089] A disadvantage of using an isochronous channel for the Command Interface is that bandwidth allocated to the Command Interface will be wasted if it does not completely fill the isochronous channels provided. In particular, bandwidth allocated for intensive applications will be wasted when those applications are not active.

[0090] It would be possible to allocate the bandwidth of the required isochronous channels dynamically, depending on how much the applications require at any one time. In particular, a host and module could initialize to a default low value bandwidth for the Command Interface isochronous channels and then request allocation of more bandwidth if an application requires a faster response. In particular, the device (host or module) requiring the extra bandwidth can contact the isochronous resource manager and request the extra bandwidth required. If available the bandwidth can then be allocated to that device. Bandwidth can be given up in the same way. The device requesting the bandwidth can then output on the existing isochronous channel using the extra bandwidth and over the existing connection.

[0091] The isochronous resource manager is a device required on the bus if isochronous channels are to be allowed. Several devices could be isochronous resource manager capable and will arbitrate to allow one device to become the isochronous resource manager.

[0092] In order for a Conditional Access Module to be put on an IEEE 1394 Serial Bus network as mentioned above, it is also necessary for transport streams to flow to and from the Conditional Access Module.

[0093] The DVB Common Interface PC card implementation carries the transport streams using dedicated electrical connections on the host and module connectors. The IEEE 1394 Serial Bus provides no such physical connection, but only a set of isochronous channels providing logical connections between host and module. Therefore, a connection protocol needs to be defined to allow transport stream connections to be made between host and module.

[0094] The IEC 1883 implementations regarding Serial Bus management are compliant with the IEEE 1394 Interface Standard. According to these implementations and standards, an item of equipment, known as a node, connected to the IEEE 1394 through an interface board shall be cycle master capable. In other words, a cycle master unit is provided to control the timing of the isochronous channels used by all the nodes on the IEEE 1394 Serial Bus. Each node is also isochronous resource manager capable, such that an isochronous resource manager can control the allocation of isochronous resources to nodes on the IEEE 1394 Serial Bus. In other words, the resource manager can set up particular isochronous channels between particular nodes. Finally, a node which is transmitting or receiving isochronous packets shall provide plug control registers which themselves are used to set up and control audio/visual connections between nodes on the IEEE 1394 Serial Bus.

[0095] The protocols described in the IEC 1883 standard provide a method of controlling isochronous data flow between devices connected using the IEEE 1394 Serial Bus.

[0096] According to this standard, devices have input and output plugs for transmitting and receiving isochronous data flows. Each plug can only carry one isochronous data flow and that isochronous data flow is carried in one isochronous channel which itself can carry only one isochronous data flow.

[0097] A connection is made between two plugs and defines the isochronous channel number and the bandwidth required.

[0098] Connections can be overlaid on one plug to allow an isochronous data flow to be connected to more than one destination plug. In this case, although there is more than one connection, there is still only one isochronous channel carrying the data flow.

[0099] Figure 9 illustrates a possible configuration where a Conditional Access Module 38 is connected on an IEEE 1394 Serial Bus.

[0100] Thus, it is proposed to use isochronous channels to carry the MPEG transport streams. In particular, it is proposed that isochronous channels will use IEC 1883 protocols to carry the MPEG transport stream using the common isochronous packet (CIP) header described above.

[0101] Figure 10 illustrates the various protocol layers making up the appropriate protocol stack.

[0102] Thus, the upper layers correspond to the MPEG upper layers which would be used for the Common Interface, such that the higher generic protocol layers of the Common Interface do not need any modifications.

[0103] To implement this system it is proposed that the Conditional Access Module and the host receiver each include at least one input plug and one output plug as defined in IEC 1883, a master input and output plug control register as defined in IEC 1883 and an input and output plug control register for each plug implemented, as defined in IEC 1883.

[0104] For the arrangement illustrated in Figure 9, there will now be described a connection protocol which could be used to transmit transport streams between the host receiver 30 and Conditional Access Module 38.

[0105] First, the host 30 identifies all the DVB Common Interface Modules present on the network, preferably using the sub-unit mechanism defined in the AV/C-CTS protocol. The host 30 then requests from the isochronous resource manager the use of two isochronous channels each of the bandwidth necessary to carry the required
transport stream.

[0106] The host 30 then configures the input plug control register of the Conditional Access Module 38 to receive a transport stream on the first isochronous channel and configures its own output plug control register to output the transport stream on that channel. The host 30 then configures the output plug control register of the module to output the transport stream on the second isochronous channel and configures its own input plug control register to receive the transport stream on that channel.

[0107] The host 30 can then send a scrambled transport stream over the first isochronous channel and receive the descrambled transport stream back from the module 38 on the second isochronous channel.

[0108] Since the Conditional Access Module 38 is not connected to any particular device, it is no longer essential that a descrambled clear transport stream must be sent back to the source 30 of the scrambled stream. Thus, the Conditional Access Module 38 may be used more flexibly and may send a clear stream to a different device to that from which the scrambled stream was received.

[0109] Clearly, the scrambled transport stream received by receiver 30 must be sent to the Conditional Access Module 38. However, it is then possible for the Conditional Access Module to send the descrambled transport stream only to the digital video recorder 32 (through the receiver) or to both the digital video recorder 32 and the receiver 30. Thus, the Conditional Access Module 38 must transmit to either one or two destinations.

[0110] In the example illustrated in Figure 9, a first proposal is that the receiver 30 will have the necessary transport stream switching resources to receive the transport stream from the Conditional Access Module 38 and then reroute it on to the digital video recorder 32 via a third isochronous channel either as a normal IEEE Serial Bus transmission or as a Common Interface transport stream. Indeed, these resources will be used to route clear streams to the digital video recorder 32 when the Conditional Access Module 38 is not required. This proposal would allow only the program stream of interest to be sent to the digital video recorder 32, rather than the whole transport stream.

[0111] A second proposal is to use two transport stream connections, namely one from the host 30 to the module 38 and the other from the module 38 to the digital video recorder 32.

[0112] These connections could be set up and configured in a similar way to that described above, but with the second isochronous channel being set up between the module 38 and the digital video recorder 32. This would have the advantage of avoiding the need for the host receiver 30 to itself switch the program back to the digital video recorder 32. This in turn, will allow the use of the resources in the host receiver 30 for other applications or a cheaper implementation of the host.

[0113] Of course, in this case, the digital video recorder 32 would receive the whole transport stream, but could be arranged to strip out all of the streams which are not of interest either under the direction of the host 30 or in a stand alone mode.

[0114] The arrangement of Figure 9 may also be configured as described below.

[0115] Instead of the host receiver 30 switching a required program stream back out to the digital video recorder 32, overlaid connections can be used. In particular, having set up isochronous connections between the host receiver 30 and the Conditional Access Module 38, the host receiver 30 then overlays a connection from the Conditional Access Module 38 to the digital video recorder 32. As mentioned above, overlaying a connection uses the same isochronous channel, but directs it to an additional destination, in this case, the digital video recorder 32.

[0116] This configuration has the advantage that the switching resources of the host receiver 30 are not used and also that no additional bandwidth is used in transmitting the transport stream on to the digital video recorder 32 in addition to the host receiver 30.

[0117] Once again, the second destination, in this case the digital video recorder 32, would receive the whole transport stream. However this, could be an advantage where the second destination is perhaps a display in another room. In particular, it would allow the selection of the program stream to be made independently from the host receiver 30.

[0118] The use of Conditional Access Modules in conjunction with the IEEE Serial Bus brings about the possibility of communication of another type not previously considered for the IEEE 1394 Serial Bus. As an example, rather than return a descrambled transport stream to the host receiver 30, the transport stream can be passed on to a second Conditional Access Module (not shown) for further processing or descrambling of other virtual channels of the transport stream. To do this, it is proposed that the host receiver 30 contacts the isochronous resource manager to request a third isochronous channel, configures the output control register of the first module 38 to remove the return connection between the first module 38 and the host 30 and sets up a new connection between the first 38 and second modules using the second isochronous channel. The host 30 then configures the input plug register of the second module to receive a transport stream on the second isochronous channel and configures the output plug control register of the second module to set up a connection between the second module and the host 30 using the third isochronous channel. It then configures its own input plug control register to receive the transport stream on the third isochronous channel.

[0119] Thus, whether all available modules or a selection of modules are utilised is at the option of the host.

[0120] According to the PC card implementation of the Conditional Access Module, the full transport stream as received by the host receiver is passed to the Conditional Access Module. Placing the transport stream at this level
simplifies the interface, since the host receiver needs no knowledge of the operation of the Conditional Access Module. In particular, the Conditional Access Module can receive and use private streams of which the host receiver has no knowledge or understanding. These streams can include descrambling information, subscription information, etc.

[0121] The DVB Common Interface defines the transport stream bit rate as being at least 58 Mbit/s. Hence, to carry a transport stream to and from a Conditional Access Module over the IEEE 1394 Serial Bus requires a minimum of 116 Mbit/s of bandwidth. Furthermore, each additional module would require at least a further 58 Mbit/s of bandwidth. The IEEE 1394 Serial Bus has various standard bandwidths. However, as will be apparent from the above, the 100 Mbit/s Serial Bus would be precluded and the 400 Mbit/s Serial Bus would soon be filled up using Conditional Access Modules.

[0122] According to the IEEE 1394 Serial Bus standards, 63 devices may be used on any one bus. However, with Conditional Access Modules requiring such large bandwidths, there is a relatively low limit on the number of independent Modules which can be used on the bus.

[0123] Transmission of the full transport stream over the network is a very inefficient use of bandwidth, since any one Conditional Access Module usually descrambles only one or two virtual channels of the transport stream. The Conditional Access Module may also require other data streams in the transport stream, but these are generally of relatively small bit rates compared to the program streams containing video and audio information. Hence, it is likely that a large amount of information will be transferred around the network with very little of it being processed by the Conditional Access Modules. This results in a restriction of the applications of the Conditional Access Module and other devices using the IEEE 1394 Serial Bus.

[0124] One solution to this problem would be for the receiver to send out only those program streams which are to be processed. Since generally only one or two program streams are used at once, this would dramatically reduce the bit rate required and since the transport stream is a stream of packets, packets may be stripped out independently of the packets of other streams so as to leave a transport stream which is still compatible with the DVB Common Interface.

[0125] However, a Conditional Access Module usually requires additional streams containing entitlement and encryption information. If the host receiver cannot identify these streams, it is not able to determine which streams to send to each Conditional Access Module. Indeed, even if these streams can be identified, there may be so many different streams of information, that the number is beyond the capability of the host receiver to filter out and send.

[0126] Clearly, if these additional streams are not sent to the Conditional Access Module, then correct functioning of the module cannot be achieved.

[0127] A transport stream usually contains a table or map, for example MPEG Program Specific Information (PSI), indicating the various program streams present and other identifying maps. However, since not all the data in the transport stream need be identified in the table, a host receiver may not be able to identify the presence of certain data.

[0128] It would be possible for a Conditional Access Module to signal to the host receiver which streams it requires. However, this would necessitate an extension or modification to the higher layer functionality of the Common Interface standards and this is preferably to be avoided.

[0129] Figure 11(a) illustrates schematically time multiplexed data streams, together with an associated table.

[0130] Figure 11(b) illustrates schematically the table of Figure 11(a).

[0131] As will be apparent, from the table, a device can determine the content of associated data streams, for example that data stream 1 relates to program Channel D. However, as illustrated, not all the data streams need be identified in the table.

[0132] It is proposed here that rather than have the host receiver identify the program streams which are required, it should identify the program streams which are known not to be required. In this way, the host receiver can safely strip out all the program streams which are not required whilst ensuring that any other data streams required by the Conditional Access Module will still be present in the transport stream sent to the Conditional Access Module.

[0133] Thus, for the example of Figure 11, if Channel B is to be descrambled by the Conditional Access Module, then the host receiver strips out streams 1, 2 and 6, which it can determine from the table relate to broadcast Channels A, C and D. In this way, if there is any additional information in streams 3 and 5 which are required by the Conditional Access Module, this will still be sent to the Conditional Access Module.

[0134] In the case of MPEG streams, only program streams the host receiver can identify from the MPEG Program Specific Information (PSI) data are removed. This PSI data is specified in the MPEG-2 system specification (ISO/IEC 13818-1 Generic Coding of Moving Picture and Associated Audio Systems) and is always present in an MPEG transport stream and therefore can be used to identify the program streams present. By removing known program streams, private data of which the host receiver could have no knowledge is retained in the transport stream sent over the Common Interface on the IEEE 1394 Serial Bus.

[0135] As the dominant portion of the transport stream will consist of video program streams, removing unwanted video program streams will significantly reduce the bandwidth required by the Common Interface on the IEEE 1394 network.
Claims

1. A digital multi-media receiver (30) for use with a Conditional Access Module (38) using a Common Interface comprising:

- an output for an IEEE 1394 Serial Bus for transmitting a transport stream to a Conditional Access Module (38) on the bus;
- a reader for reading the contents of a transport stream and identifying data which is not required for processing by a Conditional Access Module (38);
- a stripper for stripping out at least some of the identified unrequired data from the transport stream;
- a coder (40) for producing appropriate AV/C-CTS commands with headers including appropriate AV/C-CTS opcodes corresponding to transport objects of the Command Interface; and
- a transmitter for transmitting, through the output and over an IEEE 1394 Serial Bus, the AV/C-CTS commands produced by the coder (40) and all of the remaining data of the transport stream which has not been stripped; wherein:

the Conditional Access Module (38) returns a processed transport stream to the receiver (30) over the IEEE 1394 Serial Bus, together with AV/C-CTS commands with headers including AV/C-CTS opcodes corresponding to transport objects of the Command Interface; and

the receiver (30) is arranged to receive the processed transport stream and AV/C-CTS commands and further comprises a decoder (42) for producing appropriate Common Interface objects from the received AV/C-CTS commands.

2. A digital multi-media receiver according to claim 1 wherein said receiver is a digital video receiver (30) for handling at least video data.

3. A network of digital multi-media devices connected by means of an IEEE 1394 Serial Bus, the network comprising:

- a receiver (30) for transmitting a transport stream over the IEEE 1394 Serial Bus using a Common Interface; and
- a Conditional Access Module (38) for receiving a transport stream over the IEEE 1394 Serial Bus using the Common Interface; wherein

the Conditional Access Module (38) returns a processed transport stream to the receiver (30) over the IEEE 1394 Serial Bus, together with AV/C-CTS commands with headers including AV/C-CTS opcodes corresponding to transport objects of the Command Interface; and

the receiver (30) is arranged to receive the processed transport stream and AV/C-CTS commands and further comprises a decoder (42) for producing appropriate Common Interface objects from the received AV/C-CTS commands.

4. A network according to claim 3 wherein said first (30) and second (38) devices are digital video devices for handling at least video data.

5. A receiver according to claim 2 or a network according to claim 4 wherein the transport stream is an MPEG-2 transport stream.

6. A receiver or network according to any preceding claim wherein the transport stream is transmitted in isochronous channels under the IEC 1883 format.

7. A receiver or network according to any preceding claim wherein the unrequired data is identified by reference to program specific information in the transport stream.

Patentansprüche

1. Digitaler Multimedia-Empfänger (30) für die Benutzung mit einem Modul für bedingten Zugriff [Conditional Access Module] (38) unter Verwendung einer allgemeinen Schnittstelle [Common Interface], mit einem Ausgang für einen seriellen IEEE-1394 Bus, um auf dem Bus einen Transportstrom zu einem Conditional Access Module (38) zu senden, mit einem Leser zum Lesen der Inhalte eines Transportstroms und zum Identifizieren der Daten, die für die Verarbeitung durch ein Conditional Access Module (38) nicht benötigt werden, mit einem Stripper zum Herausfiltern wenigstens einiger der identifizierten, nicht benötigten Daten aus

2. Digitaler Multimedia-Empfänger nach Anspruch 1, bei dem der Empfänger ein digitaler Videempfänger (30) für die Behandlung zumindest von Videodaten ist.

3. Netzwerk von digitalen Multimediageräten, die über einen seriellen IEEE-1394-Bus miteinander verbunden sind, wobei das Netzwerk aufweist:

  - einen Leser zum Lesen der Inhalte eines Transportstroms und zum Identifizieren der Daten, die für die Verarbeitung durch das Conditional Access Module (38) nicht benötigt werden,
  - einen Stripper zum Herausfiltern wenigstens einiger der identifizierten, nicht benötigten Daten aus dem Transportstrom, einen Kodierer (40) zum Erzeugen von geeigneten AV/C-CTS-Befehlen mit Headern, die geeignete AV/C-CTS-Opcodes enthalten, die Transportobjekten des Common Interfaces entsprechen, und einen Sender, um durch den Ausgang und über einen seriellen IEEE-1394-Bus die von dem Kodierer (40) erzeugten AV/C-CTS-Befehle und alle übrigen Daten des Transportstroms zu senden, die nicht herausgefiltert wurden, wobei das Conditional Access Module (38) einen verarbeiteten Transportstrom zusammen mit AV/C-CTS-Befehlen mit Headern zurückführt, die geeignete AV/C-CTS-Opcodes enthalten, die Transportobjekten des Common Interfaces entsprechen, wobei der Empfänger (30) ausgebildet ist, um den verarbeiteten Transportstrom und AV/C-CTS-Befehle zu empfangen und ferner einen Dekodierer (42) aufweist, um aus den empfangenen AV/C-CTS-Befehlen passende Common-Interface-Objekte zu erzeugen.

4. Netzwerk nach Anspruch 3, bei dem das erste Gerät (30) und das zweite Gerät (38) digitale Videogeräte für die Behandlung zumindest von Videodaten sind.

5. Empfänger nach Anspruch 2 oder Netzwerk nach Anspruch 4, bei denen der Transportstrom ein MPEG-2-Transportstrom ist.

7. Empfänger oder Netzwerk nach einem der vorhergehenden Ansprüche, bei denen die nicht benötigten Daten unter Bezugnahme auf programmspezifische Informationen in dem Transportstrom identifiziert werden.

Revendications

1. Récepteur numérique multimédia (30) destiné à être utilisé avec un module d’accès conditionnel (38) utilisant une interface commune comprenant :

- une sortie pour un bus série IEEE 1394 pour transmettre sur le bus un courant de transport à un module d’accès conditionnel (38) ; 
- un lecteur pour lire le contenu d’un courant de transport et identifier des données dont il n’est pas requis qu’elles soient traitées par un module d’accès conditionnel (38) ; 
- un séparateur pour séparer au moins certaines des données identifiées non requises du courant de transport ; 
- un codeur (40) pour produire des commandes AV/C-CTS appropriées avec des en-têtes incluant des codes optiques AV/C-CTS appropriés correspondant à des objets de transport de l’interface de commande ; et 
- un émetteur pour transmettre, par l’intermédiaire de la sortie et sur un bus série IEEE 1394,
les commandes AV/C-CTS produites par le codeur (40) et l'ensemble des données restantes du courant de transport n'ayant pas été séparées ; dans lequel
le récepteur (30) est agencé pour recevoir un courant de transport traité renvoyé par le module d'accès conditionnel (38) sur le bus série IEEE 1394, en même temps que des commandes AV/C-CTS avec des en-têtes incluant des codes optiques AV/C-CTS correspondant à des objets de transport de l'interface de commande ; et le récepteur (30) comprend en outre un décodeur (42) pour produire des objets appropriés de l'interface commune à partir des commandes AV/C-CTS reçues.

2. Récepteur numérique multimédia selon la revendication 1, dans lequel ledit récepteur est un récepteur numérique vidéo (30) pour traiter au moins des données vidéo.

3. Réseau de dispositif numérique multimédia connecté au moyen d'un bus série IEEE 1394, le réseau comprenant :
   un récepteur (30) pour transmettre un courant de transport sur le bus série IEEE 1394 en utilisant une interface commune ; et un module d'accès conditionnel (38) pour recevoir un courant de transport sur le bus série IEEE 1394 en utilisant l'interface commune ; dans lequel
   le récepteur (30) comporte un lecteur pour lire le contenu d'un courant de transport et identifier des données dont il n'est pas requis qu'elles soient traitées par le module d'accès conditionnel (38) ; un séparateur pour séparer au moins certaines des données identifiées non requises du courant de transport ; un codeur (40) pour produire des commandes AV/C-CTS appropriées avec des en-têtes comportant des codes optiques AV/C-CTS appropriés correspondant à des objets de transport de l'interface de commande ; et un émetteur pour transmettre vers le module d'accès conditionnel sur le bus série IEEE 1394 les commandes AV/C-CTS produites par le codeur (40) et l'ensemble des données restantes du courant de transport n'ayant pas été séparées ; dans lequel
   le module d'accès conditionnel (38) renvoie un courant de transport traité au récepteur (30) sur le bus série IEEE 1394, en même temps que des commandes AV/C-CTS avec des en-têtes incluant des codes optiques AV/C-CTS correspondant à des objets de transport de l'interface de commande ; et le récepteur (30) est agencé pour recevoir le courant de transport traité et les commandes AV/C-CTS et comprend en outre un décodeur (42) pour produire des objets appropriés de l'interface commune provenant des commandes AV/C-CTS reçues.

4. Réseau selon la revendication 3, dans lequel lesdits premier (30) et second (38) dispositifs sont des dispositifs vidéo numériques pour traiter au moins des données vidéo.

5. Récepteur selon la revendication 2 ou réseau selon la revendication 4, dans lequel le courant de transport est un courant de transport MPEG-2.

6. Récepteur ou réseau selon l'une quelconque des revendications précédentes, dans lequel le courant de transport est transmis dans des canaux isochrones en utilisant le format IEC 1883.

7. Récepteur ou réseau selon l'une quelconque des revendications précédentes, dans lequel les données non requises sont identifiées en référence à des informations spécifiques de programme dans le courant de transport.
