Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

[0001] This invention relates to a device for cleaning the outer circumferential surface of rotary cylinders or rollers used in printing machines or in other types of machine such as paper and/or film production and processing machines, on which deposits of various materials, such as ink, form and have to be removed for proper machine operation.

[0002] The state of the art comprises cleaning devices provided with two shafts for unwinding and rewinding a fabric which is made to adhere to the rotary cylinder or roller by means of a presser member, which can be in the form of an air chamber or a blade of flexible metal or resilient material (e.g. US-A-4,986,182 and US-A-4,344,361).

[0003] Because of their characteristics and method of operation, these conventional devices have drawbacks in use, and do not ensure either adequate cleaning or optimum fabric and detergent consumption. Specifically, in the case of devices comprising an air chamber, this performs two functions, namely those of bringing the fabric into contact with the cylinder and of pressing it against the cylinder. The air is fed into the air chamber and then discharged several times during each cleaning cycle, to the detriment of the elasticity of the chamber, which undergoes variation both because of pressure reduction and leakages, with immediate negative effects on operation, and because of continuing decay in the characteristics of the rubber from which the chamber is constructed. Excessive chamber air pressure or wear involve the risk of chamber bursting with consequent danger to the operator. To this can be added the traction effect exerted by the rotary cylinder on the chamber via the fabric, causing chamber deformation which cannot always be compensated by the pressure exerted by it in the contact region. In the particular case of cylinders which do not have a continuous outer circumferential surface but instead comprise, as for example in the case of blanket cylinders, a gap in the direction of the generating line, this deformation is even more evident, resulting in vibration on passing said gap during rotation, this vibration adversely affecting the quality of the contact offered by the air chamber.

[0004] In the case of cleaning devices provided with a contact blade or resilient material, the pressure exerted on the cylinder via the fabric is not always uniform along the entire cylinder length, and any irregularities in its surface or even minimum misalignment between the blade or resilient material and the cylinder axis prevent its proper cleaning. In the case of the aforesaid discontinuous cylinders the said vibration problem also exists, in that the blade is unable to maintain the fabric in contact with the cylinder surface, not because of deformation but because of its limited flexibility and elasticity.

[0005] In an attempt to at least partly solve the said problems, it is usual to increase the cleaning time even though this results in greater fabric and detergent consumption.

[0006] The main object of the invention is to provide a cleaning device which is quick and simple in use and results in proper and efficient cylinder or roller cleaning and an appreciable saving in fabric and detergent.

[0007] This and other objects which will be more apparent from the ensuing detailed description are attained by a cleaning device in accordance with the accompanying claims.

[0008] The invention will be more apparent from the detailed description of a preferred embodiment thereof given hereinafter by way of nonlimiting example and illustrated on the accompanying drawings, on which:

Figure 1 is a perspective schematic view of the cleaning device of the invention, together with a cylinder to be cleaned by the device;

Figure 2 is a vertical cross-section through the cleaning device;

Figure 3 is a side view of the device;

Figure 4 is a schematic view, with some parts omitted for representational simplicity, showing the cleaning device of the invention and the means which enable it to be rapidly mounted on and removed from the parts which support it.

[0009] In the figures, the reference numeral 1 indicates overall the device of the invention. The device is intended to clean the cylindrical surface of a cylinder 2, for example of a printing machine, without the cylinder having to be removed from the machine which rotates it (not only during printing but also during its cleaning by the device of the invention).

[0010] The cleaning device is located in front of and parallel to the cylinder as shown in the figures.

[0011] The printing machine comprises a support structure shown schematically as two parallel side walls 3 in which the cylinder 2 is mounted. Two lateral shoulders 4, 5, forming part of the device of the invention and intended for the support and movement of the actual cleaning part 6 of the device, are fixed to said side walls, for example removable, by any known means, for example by screw means. This cleaning part 6 is movable away from and towards the cylinder to be cleaned. The cleaning part 6 comprises at its respective ends two parallel shoulders 7, 8. Between these shoulders 7, 8 there is rotatably and removably supported a shaft 9 on which a fabric 10 operating on the cylinder 2 for its cleaning is directly or indirectly wound. Constant lengths of the fabric 10 are unwound intermittently from the shaft 9 at, for example of a printing machine, without the cylinder having to be removed from the machine which rotates it (not only during printing but also during its cleaning by the device of the invention).

[0012] During operation, the fabric 10 passes from one shaft 9 to the other 10, coming into contact with the surface of the cylinder 2 to be cleaned in correspondence with a presser member 12 described in detail here-
[0013] As stated, the two shafts 9 and 11 are removable mounted between the two shoulders 7 and 8 by a known rapid-release support system comprising for example support elements having a cavity into which the end of the shafts 9 and 11 is inserted and retained therein by a pin or ball with a counteracting spring.

[0014] Such an arrangement enables the fabric to wind onto and unwind from the shafts 9 and 11, not directly but by way of tubes 13, 14 for example of plastic or cardboard which are mounted on said shafts (before being mounted between the shoulders 7, 8), to which the tubes 13, 14 can be secured by the action of pneumatic or mechanical radial expansion plugs 15 emerging from the shafts.

[0015] Using this solution the fabric 10 can be quickly replaced and easily reused, as the shafts 9 and 11 can be quickly removed and the fabric support tubes 13, 14 be replaced on the two shafts without having to manually unwind the fabric from one shaft and then rewind it onto the other.

[0016] The lack of the fabric is indicated by conventional sensors, for example microswitches, not shown, which provide a warning and halt the cleaning operation.

[0017] The cleaning part 6 also comprises, fixed to the shoulders 7, 8, a crosspiece 16 partially covered with a housing 17, for example of stainless steel. The presser member 12 comprising a tubular chamber 18 of elastic material, preferably rubber, is fixed to the crosspiece 16. This tubular chamber comprises a substantially flat base 18A incorporating a metal plate 19 embedded along its periphery in the elastic material to form a perimetral flange 24 to which, at least at one of its points, there is fixed a projecting nozzle 20 incorporating a non-return valve, to engage in an exit port 21 of a duct 22 passing longitudinally along the crosspiece 16. A metal frame 23, fixed to the crosspiece 16 by studs distributed along its perimeter, locks the tubular chamber by securing it to the crosspiece via said flange 24.

[0018] The tubular chamber 18 is intended to be filled via the duct 22 with water or another fluid or, for some applications, with viscoelastic substance, for example a polymer, at a predetermined pressure, to form a presser member (for the fabric against the perimeter of the cylinder 2 to be cleaned) which presents an adequate region of contact against the cylinder to be cleaned, in terms both of dimensions and of elasticity.

[0019] In contrast to known pneumatic cleaning devices in which the approach and withdrawal of the fabric 10 to and from the cylinder 2 and the application of the fabric against the cylinder are achieved by merely inflating/deflating an air chamber, in the device of the invention the approach and withdrawal of the fabric and its contact pressure are determined by the pneumatic cylinder-piston units 25, 26, whereas the surface optimization in the contact region and the relative degree of elasticity are determined by the hydraulic chamber 18 and are a function of the pressure of the liquid contained in it.

[0020] It is always possible to find a proper balance between the damping capacity of the chamber 18 and the necessary thrust of the pneumatic cylinder-piston units 25, 26, without having to be excessive with this latter, to the advantage of a considerable reduction in vibration and noise at their source.

[0021] In this respect, experimental tests have demonstrated the evident advantages deriving from the water or other liquid chamber 18 to reduce and absorb the vibration generated by the rotation of the cylinder 2 and its contact with the device of the invention, and to effectively compensate the pressure differences encountered along the contact region caused by flexure or by minimal misalignment between the device and the axis of the cylinder 2, and by imperfections in the surface to be cleaned (sometimes deriving from non-uniform deposition of the residues to be removed).

[0022] The fabric 10 can thus adhere perfectly to the cylinder 2, to best perform its mechanical action, which contributes to chemical detergent action for cleaning purposes, and to air blowing action for drying purposes.

[0023] As stated, two pneumatic cylinder-piston units 25, 26 are provided for moving the cleaning part 6 away from and towards the cylinder 2. These cylinder-piston units are visible in Figures 3 and 4, and rotate the cleaning part 6 in such a manner as to apply it to or withdraw it from the cylinder. Each pneumatic cylinder-piston unit 25, 26 is rigid with the fixed shoulders 4, 5. A U-piece or fork 30A is provided at the end of the relative rod 30. In each U-piece 30A there is provided a pin 31 projecting outwards from each of the shoulders 7, 8. These have a further pin 32 acting as a pivot for the movable cleaning part 6 and arranged as described hereinafter in a seat provided in the fixed shoulders 4, 5. By operating the pneumatic cylinder-piston units 25, 26 the cleaning part 6 is made to approach or withdraw from the cylinder 2. Advantageously, as described hereinafter, the connection between the cleaning part 6 and the fixed shoulders 4, 5 is such (see Figure 4) as to enable it to be removed.

[0024] On the hydraulic chamber 18 there is superposed a diaphragm 37, for example of nylon or rubber, which becomes interposed between said chamber and the fabric 10 to facilitate, by virtue of its low coefficient of friction, the sliding of the fabric by being resistant to abrasion and to the detergents used. As can be seen in Figure 2, the diaphragm is fixed along its perimeter to the crosspiece 16, between this and the housing 17, by means of the same screws 40 which fix the housing to the crosspiece.

[0025] If cleaning blanket cylinders of printing machines, it has been found to be effective to use for example the same rubber as the blanket for the chamber covering diaphragm, by virtue of its gauged thickness, its perfect surface finish, its tear resistance and its total compatibility with the detergents used on it.

[0026] The filling liquid is fed into the tubular chamber 18 on installation, via the non-return valve mounted in
the nozzle or nozzles 20, until attaining the required pressure, indicated by a pressure gauge (not shown). After a number of wash cycles and several months of operation it may be necessary to restore the correct liquid pressure, easily done by using any source having the required pressure.

[0027] In an advantageous variant of the device, the operating pressure of the liquid contained in the chamber 18 is automatically restored after a predetermined time and/or after a given number of wash cycles, this being achievable for example by means of a sensor, for example a pressure switch, operating via a circuit on a feed valve for the pressurized liquid.

[0028] In the top of the crosspiece 16 there is located a detergent distributor consisting of a tube 50 having a series of holes of suitable diameter and distance apart, extending in the longitudinal direction of the crosspiece 16 within an outwardly open channel 50A. To ensure good distribution the detergent liquid is fed from both ends and/or at several points of the distributor tube 50 through valves from a pressurized feed source, not shown. The exit holes for the detergent liquid face the outer housing 17, adjacent to them, so that the detergent is not sprayed directly onto the fabric but instead reaches it "by reflection" and in this manner well distributed and without soiling adjacent machine parts.

[0029] A tube 51 with holes along its entire length and arranged between the fixed shoulders 4 and 5 feeds drying air against the surface of the cylinder 2 at the end of the cycle, this tube being connected to a valve-controlled compressed air source.

[0030] To produce constant intermittent advancement of the piece 10 there is provided (see Figure 3) on one of the shoulders 7, 8 a further pneumatic cylinder-piston unit 40A of fixed stroke. The rod 41 of this unit acts on a lever 42 via a transverse pin 43 thereof. The lever 42 rotates the support for the shaft 11 (which carries the soiled fabric), to which it is connected by a "freewheel" anti-return device. A second lever 44 is connected to a mechanical feeler 45 which under the action of a spring (not shown) adheres to the clean fabric present on the shaft 9. This lever 44 varies its position (by rotating) on the basis of the position assumed by the feeler 45.

[0031] When in operation, the cylinder-piston unit 40 rotates (clockwise) the lever 42 which, under the action of a spring (not shown), then returns to its initial, rest position to halt against the lever 44.

[0032] The position of the feeler 45, the position of the lever 44 rigid with it, and consequently the rest position in which the lever 42 lies prior to its rotation vary according to the quantity (diameter) of fabric wound on the feed shaft 9.

[0033] As the fabric advancement depends on the degrees of (clockwise) rotation which the lever 42 undergoes from its initial rest position by the action of the cylinder-piston unit 40, it varies on the basis of the position assumed by the lever 42 when in its rest position.

[0034] Specifically, the closer the lever 42 lies to the rod 41, the more its stroke is utilized and the greater the rotation of the lever, hence the greater the advancement of the fabric.

[0035] The shape of the levers 42 and 44 and their relative position are chosen to provide constant fabric advancement.

[0036] In a modified embodiment, the mechanical system for advancing the fabric can be replaced by one or two electric or pneumatic motors rotating one or both the fabric-carrying shafts.

[0037] The detergent reaches the tube 50 of the cleaning part 6 via an automatic plug-in connector comprising a male part 70 rigid with the outer face of the shoulder 7 (see Figure 4), close to the pivot pin 32, and plugging into a corresponding female part 71 elastically secured to the inner side of the fixed shoulder 4 in such a manner as to be able to follow the (limited) movements of the cleaning part 6 and hence of the connector part 70 relative to the fixed shoulders 4; 5.

[0038] A second automatic plug-in connector similar to the preceding and similarly positioned, comprising the mutually insertable components 80, 81, performs the function of automatically filling the hydraulic chamber 18 to the required pressure via the duct 22. As already stated and as shown in Figure 4, the cleaning part 6 is removable. In this respect, as already indicated, the cleaning part 6 is provided, for each of the lateral shoulders 7, 8, with a cylindrical rear pin 32 and a cylindrical front support pin 31, whereas each of the fixed shoulders 4, 5 comprises, on its inner side, flat support and guide surfaces 83, 84, support and fixing elements 82, and the already stated U-pieces 30A relative to the pneumatic cylinder-piston units 25, 26.

[0039] To mount the removable cleaning part 6 of the device of the invention on the machine for which it is intended, it is brought into contact with the fixed shoulders 4, 5 rigid with the machine, by resting its rear support pins 32 on the flat support and guide surfaces 83 of both the fixed shoulders 4, 5, then the entire part 6 is rotated about the pivots in the form of the rear pins 32 until the front support pins 31 enter into contact with the support and guide surfaces 81. The movable part 6 is then thrust in the direction of the cylinder 2 until the rear pins 32 enter the hollow support elements 82 and the front pins 31 enter the U-pieces 30A.

[0040] For each side, the arm 90 of an outer slideable ring 91 mounted on the support element 82 is then slid axially towards the part 6 to close the hollow region of the support element 82 previously used for inserting the pin 32 into it. This ensures that the pin 32 is retained in the support element 82, the aperture of which is closed by the ring 91 and by the entire movable part 6 against the shoulders 4 and 5 fixed to the machine.

[0041] Operating the pneumatic cylinder-piston units 25 and 26 causes the cleaning part 6 to move about its rotation pivots in the form of the rear support pins 32, to cause it to move towards or away from the surface of the rotary cylinder 2.
[0042] On mounting the cleaning part 6 in the aforesaid manner, when thrusting said part in the direction of the cylinder 2 the two male and female components of the plug-in connectors 70, 71 and 80, 81 automatically engage each other without the operator having to act on them.

[0043] According to a particular aspect of the invention, one and the same device can be used to clean two or even three adjacent cylinders or rollers. For this purpose it is sufficient, for example, to make the device movable (together with the shoulders 4, 5, no longer fixed) along rectilinear guides parallel to the cylinders, either manually or by motors, for example pneumatic.

[0044] Alternatively it can be made rotatable about a support axis parallel to the axis of the crosspiece.

[0045] When in operation the device performs four main functions, namely detergent feed and distribution, fabric advancement, approach to and withdrawal from the cylinder, and cylinder drying.

[0046] On cycle commencement the detergent is fed in the correct quantity to the distributor tube 50 which sprays it onto the fabric along its entire length.

[0047] The fabric wetted in this manner is made to adhere to the rotary cylinder 2 in the region in front of the chamber 18, under the action of the pneumatic cylinder-piston units 25 and 26 which move the movable part 6.

[0048] During the next stage these latter retract the movable part 6 from the cylinder so that the fabric is no longer in contact with it and can be advanced by unwinding it from the feed shaft 9 and winding it onto the take-up shaft 11. Detergent is again sprayed to wet the fabric 10 prior to its advancement.

[0049] The cycle comprising detergent distribution, fabric advancement and withdrawal is repeated a number of times in accordance with the program chosen on the basis of the quantity of impurities and residues to be removed from the cylinder.

[0050] After washing, an air blast from the tube 51 dries the cylinder 2.

Claims

1. A device for cleaning the outer circumferential surface of rotary cylinders and the like (2) comprising a pair of rotatable members (9, 11) for unwinding and rewinding a fabric (10), a presser means (12) cooperating with the fabric (10), means (50) for feeding onto the fabric (10) a liquid for cleaning the cylinder (2), and means (51) for feeding drying air onto the rotary cylinder (2), the pair of rotatable members (9, 11), the presser means (12) and the detergent liquid feeding means pertaining to a cleaning assembly (6) movable by pneumatic drive away from and towards the rotary cylinder (2), characterized in that the presser means (12) comprises an elastically deformable tubular chamber (18) filled with liquid at a predetermined pressure.

2. A device as claimed in claim 1, wherein the cleaning assembly (6) comprises a crosspiece (16) in which the tubular chamber (18) and the detergent liquid feeding means (50) are positioned, said crosspiece (16) lying between shoulders (7, 8) supporting the rotatable members (9, 11) for winding and unwinding the fabric and wherein the tubular chamber (18) presses on the fabric (10) via a diaphragm fixed to the crosspiece.

3. A device as claimed in the preceding claims, wherein a non-return valve is provided (at 20) at the inlet or inlets to the tubular chamber (18).

4. A device as claimed in one or more of the preceding claims, wherein means (40, 41, 42, 43, 44, 45) are provided for driving at least one of said rotatable members (9, 11) such as to intermittently advance the fabric (10) by constant lengths.

5. A device as claimed in one or more of the preceding claims, wherein the cleaning assembly (6) is removably supported by fixed shoulders (4, 5).

6. A device as claimed in the preceding claim, wherein the fixed shoulders (4, 5) can be connected to or pertain to a machine (3) which is provided with and rotatably drives the cylinder (2) to be cleaned.

7. A device as claimed in claim 5 or in claims 5 and 6, wherein the means (51) for feeding drying air onto the rotary cylinder (2) are positioned between the fixed shoulders (4, 5).

8. A device as claimed in one or more of the preceding claims, wherein the rotatable members (9, 11) for unwinding and winding the fabric (10) comprise fabric-carrying tubes (13, 14) removably supported by removable shafts (9, 11) and secured to these latter by pneumatic or mechanical expansion members (15).

9. A device as claimed in one or more of the preceding claims, wherein the tubular chamber (18) has a perimetral flange (24) via which it is secured to the crosspiece (16) by a frame (23) which presses on said flange and is fixed to the crosspiece by screws.

10. A device as claimed in one or more of the preceding claims, wherein the pneumatic drive for moving the cleaning assembly (6) comprises pneumatic cylinder-piston units (25, 26) mounted on the fixed shoulders (4, 5).

11. A device as claimed in one or more of the preceding claims, wherein the cleaning assembly (6) with the relative shoulders (7, 8) and the rotatable members (9, 11) carried by these latter for winding and un-
winding the fabric (10) form a unit which is hinged to the fixed shoulders (4, 5) and is rotated by the pneumatic cylinder-piston units (25, 26) mounted on the fixed shoulders.

12. A device as claimed in one or more of the preceding claims, wherein automatic plug-in connectors (70, 71; 80, 81) are provided between the fixed shoulders (4, 5) and those shoulders (7, 8) associated with the crosspieces (16), for the hydraulic connections to the tubular chamber (18) and to the means (50) for feeding the liquid to the fabric (10).

13. A device as claimed in one or more of the preceding claims, wherein means are provided for causing it to traverse or rotate in order to clean the surfaces of two or more adjacent cylinders.

Patentansprüche

1. Vorrichtung zum Reinigen der äußeren Umfangs-Oberfläche von Drehzylindern oder dergleichen (2) mit einem Paar drehbarer Komponenten (9, 11) zum Abwickeln und Wiederaufwickeln eines Gewebes (10), einer mit dem Gewebe (10) zusammenwirkenden Pressseinrichtung (12), einer Einrichtung (50), um eine Flüssigkeit zum Reinigen des Zylin-

der (2) auf das Gewebe (10) zu leiten, und einer Einrichtung (51), um Trockenluft auf den Drehzylin-
der (2) zu leiten, wobei das Paar drehbarer Kompo-
nenten (9, 11), die Presseinrichtung und die Wasch-

flüssigkeits-Zuleitungseinrichtung zu einer Rei-
gungsanordnung (6) gehören, die durch einen pneumaticen Antrieb von dem Drehzylinder (2) weg und auf ihn zu bewegbar ist, dadurch gekenn-

zeichnet, dass die Presseinrichtung (12) eine elastisch deformierbare rohrförmige Kammer (18) auf-

weist, die mit einer Flüssigkeit bei einem vorbestimmten Druck gefüllt ist.

2. Vorrichtung nach Anspruch 1, wobei die Reinigungsanordnung (6) ein Querstück (16) umfasst, in welchem die rohrförmige Kammer (18) und die Waschflüssigkeits-Zuleitungseinrichtung (50) an-

gerichtet sind, wobei das Querstück (16) zwischen Schultern (7, 8) liegt, die die drehbaren Komponen-
ten (9, 11) zum Aufwickeln und Abwickeln des Ge-

webes tragen, und wobei die rohrförmige Kammer (18) über eine an dem Querstück befestigte Mem-

bran auf das Gewebe (10) drückt.

3. Vorrichtung nach einem der vorhergehenden An-

sprüche, wobei ein Rückschlagventil an dem Ein-
luss oder den Einlässen zu der rohrförmigen Kam-

mer (18) vorgesehen ist (bei 20).

4. Vorrichtung nach einem oder mehreren der vorher-

gehenden Ansprüche, wobei Mittel (40, 41, 42, 43, 44, 45) vorgesehen sind, um mindestens eine der drehbaren Komponenten (9, 11) anzutreiben, um so das Gewebe (10) intermittierend um konstante Län-

gen vorwärts zu bewegen.

5. Vorrichtung nach einem oder mehreren der vorher-

gehenden Ansprüche, wobei die Reinigungsanord-

nung (6) entferbar durch feststehende Schultern (4, 5) getragen wird.

6. Vorrichtung nach dem vorhergehenden Anspruch, wobei die feststehenden Schultern (4, 5) mit einer Maschine (3) verbunden werden können oder zu dieser gehören, die mit dem zu reinigenden Zylin-
der (2) ausgestattet ist und diesen drehbar antreibt.

7. Vorrichtung nach Anspruch 5 oder Anspruch 5 und 6, wobei die Einrichtung (51), um Trockenluft auf den Drehzylinder (2) zu leiten, zwischen den fest-

stehenden Schultern (4, 5) angeordnet ist.

8. Vorrichtung nach einem oder mehreren der vorher-

gehenden Ansprüche, wobei die drehbaren Kom-

ponenten (9, 11) zum Abwickeln und Aufwickeln des Gewebes (10) gewebetragende Rohre (13, 14) umfassten, die entferbar durch entferbare Wellen (9, 11) getragen werden und an diesen durch pneu-

matische oder mechanische Expansionselemente (15) befestigt sind.

9. Vorrichtung nach einem oder mehreren der vorher-

gehenden Ansprüche, wobei die rohrförmige Kam-

mer (18) einen Umfangsflansch (24) aufweist, über den es an dem Querstück (16) durch einen Rahmen (23) befestigt ist, der gegen den Flansch drückt und an dem Querstück durch Schrauben befestigt ist.

10. Vorrichtung nach einem oder mehreren der vorher-

gehenden Ansprüche, wobei der pneumatische An-

trieb zum Bewegen der Reinigungsanordnung (6) an den feststehenden Schultern (4, 5) angeordnet umbrachte pneumatische Zylinderkolben-Einheiten (25, 26) umfasst.

11. Vorrichtung nach einem oder mehreren der vorher-

gehenden Ansprüche, wobei die Reinigungsanord-

nung (6) mit den jeweiligen Schultern (7, 8) und die durch diese Letzteren getragenen drehbaren Kom-

ponenten (9, 11) zum Aufwickeln und Abwickeln des Gewebes (10) eine Einheit bildet, die drehbar an den feststehenden Schultern (4, 5) gelagert ist und durch die an den feststehenden Schultern angebrachten pneumatischen Zylinderkolben-Einhei-

ten (25, 26) gedreht wird.

12. Vorrichtung nach einem oder mehreren der vorher-

gehenden Ansprüche, wobei zwischen den festste-
henden Schultern (4, 5) und denjenigen Schultern (7, 8), die zu den Querstücken (16) gehören, selbst-
tätige Steckverbindungen (70, 71; 80, 81) für die Hydraulikverbindungen zu der rohrförmigen Kam-
er (18) und der Einrichtung (50), um die Flüssig-
keit zu dem Gewebe (10) zu leiten, vorgesehen sind.

13. Vorrichtung nach einem oder mehreren der vorher-
gehenden Ansprüche, wobei Mittel vorgesehen sind, um zu bewirken, daß sie verfahrt oder sich
dreht, um die Oberflächen von zwei oder mehreren unmittelbar benachbarten Zylindern zu reinigen.

Revendications

1. Dispositif pour nettoyer la surface circulaire exté-
rieure de cylindres rotatifs et équivalents (2) com-
prenant une paire d’éléments rotatifs (9, 11) pour
débobiner et ré-embobiner un tissu (10), un moyen
de pressage (12) coopérant avec le tissu, un moyen
(50) pour fournir sur le tissu un liquide de nettoyage
du cylindre (2), et un moyen (51) pour fournir de l’air
de séchage sur le cylindre rotatif (2), la paire d’élé-
ments rotatifs (9, 11), le moyen de pressage et le
moyen de fourniture de liquide détergent faisant
partie d’un ensemble de nettoyage (6) pouvant être
déplacé au moyen d’un entraînement pneumatique
par rapport au cylindre rotatif (2), caractérisé en
cette que le moyen de pressage (12) comprend une
chambre tubulaire (18) déformable de manière
elastique (18) remplie avec du liquide à une pres-
sion prédéterminée.

2. Dispositif tel que revendiqué dans la revendication
1, dans lequel l’ensemble de nettoyage (6) com-
prend un élément horizontal (16) dans lequel sont
positionnées la chambre tubulaire (18) et le moyen
de fourniture de liquide détergent (50), ledit élément horizontal (16) se trouvant entre deux épaulements
(7, 8) supportant les éléments rotatifs (9, 11) pour
débobiner et ré-embobiner le tissu et dans lequel la
chambre tubulaire (18) exerce une pression sur le
tissu (10) via un diaphragme fixé sur l’élément ho-
izontal.

3. Dispositif tel que revendiqué dans l’une des reven-
dications précédentes, dans lequel une valve de
non retour est fourni (à 20) à l’entrée ou aux entrées
de la chambre tubulaire (18).

4. Dispositif tel que revendiqué dans l’une des reven-
dications précédentes, dans lequel des moyens
(40, 41, 42, 43, 44, 45) sont fournis pour entraîner
au moins un desdits éléments rotatifs (9, 11) de ma-
nière à faire avancer le tissu (10) par longueurs
constantes de façon intermittente.

5. Dispositif tel que revendiqué dans une ou plusieurs
des revendications précédentes, dans lequel l’en-
semble de nettoyage (6) est supporté de façon amovible par des épaulements fixes (4, 5).

6. Dispositif tel que revendiqué dans l’une des reven-
dications précédentes, dans lequel les épaulements fixes (4, 5) peuvent être reliés ou appartenir
da une machine (3) qui en est pourvue et qui entraîne
en rotation le cylindre à nettoyer.

7. Dispositif tel que revendiqué dans la revendication
5 ou les revendications 5 et 6, dans lequel le moyen
(51) pour fournir de l’air de séchage sur le cylindre
rotatif (2) est positionné entre les épaulements fixes
(4, 5).

8. Dispositif tel que revendiqué dans une ou plusieurs
des revendications précédentes, dans lequel les éléments rotatifs (9, 11) pour débobiner et ré-em-
bobiner le tissu (10) comprend des tubes pour por-
ter le tissu (13, 14) supportés de façon amovible par
des arbres amovibles (9, 11) et solaires de ces
derniers par des éléments d’expansion pneumati-
ques ou mécaniques (15).

9. Dispositif tel que revendiqué dans une ou plusieurs
des revendications précédentes, dans lequel la
chambre tubulaire (18) possède une flasque péri-
phérique (24) au moyen de laquelle elle est solidaire
de l’élément horizontal (16) par un cadre qui pres-
se l’élément horizontal par des vis.

10. Dispositif tel que revendiqué dans une ou plusieurs
des revendications précédentes, dans lequel l’en-
traînement pneumatique pour déplacer l’ensemble
de nettoyage (6) comprend des unités à cylindre et
piston (25, 26) montées sur les épaulements fixes
(4, 5).

11. Dispositif tel que revendiqué dans une ou plusieurs
des revendications précédentes, dans lequel l’en-
semble de nettoyage (6) avec les épaulements re-
latif (7, 8) et les éléments rotatifs (9, 11) supportés
par ces derniers pour débobiner et ré-embobiner le
tissu (10) forment une unité qui est accrochée aux
épaulements fixes (4, 5) et est mue en rotation par
les unités à cylindre et piston (25, 26) montées sur
les épaulements fixes (4, 5).

12. Dispositif tel que revendiqué dans une ou plusieurs
des revendications précédentes, dans lequel des
connecteurs par enfichage (70, 71 ; 80, 81) sont
fournis entre les épaulements fixes (4, 5) et les
épaulements (7, 8) associés aux éléments horizon-
taux (16) pour les connexions hydrauliques à la
chambre tubulaire (18) et au moyen pour fournir le
liquide au tissu (10).
13. Dispositif tel que revendiqué dans une ou plusieurs des revendications précédentes, dans lequel des moyens sont fournis pour le faire traverser ou tourner de façon à nettoyer les surfaces de deux ou plusieurs cylindres adjacents.
