Note: Within nine months of the publication of the mention of the grant of the European patent in the European Patent Bulletin, any person may give notice to the European Patent Office of opposition to that patent, in accordance with the Implementing Regulations. Notice of opposition shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
TECHNICAL FIELD

[0001] The present invention relates to a power generation system and method, and especially relates to a hybrid power generation system which employs various methods to generate electricity and/or mechanical power employing a solid oxide fuel cell.

BACKGROUND OF THE INVENTION

[0002] Alternative transportation fuels have been represented as enablers to reduce toxic emissions in comparison to those generated by conventional fuels. At the same time, tighter emission standards and significant innovation in catalyst formulations and engine controls has led to dramatic improvements in the low emission performance and robustness of gasoline and diesel engine systems. This has certainly reduced the environmental differential between optimized conventional and alternative fuel vehicle systems. However, many technical challenges remain to make the conventionally-fueled internal combustion engine a nearly zero emission system having the efficiency necessary to make the vehicle commercially viable.

[0003] Alternative fuels cover a wide spectrum of potential environmental benefits, ranging from incremental toxic and carbon dioxide emission improvements (reformulated gasoline, alcohols, LPG etc.) and to significant toxic and carbon dioxide emission improvements (natural gas, DME etc.). Hydrogen is clearly the ultimate environmental fuel, with potential as a nearly emission free internal combustion engine fuel (including CO₂ if it comes from a non-fossil source). Unfortunately, the market-based economics of alternative fuels or new power train systems are uncertain in the short to mid-term.

[0004] The automotive industry has made very significant progress in reducing automotive emissions for both the mandated test procedures and the "real world". This has resulted in some added cost and complexity of engine management systems, yet those costs are offset by other advantages of computer controls: increased power density, fuel efficiency, drivability, reliability and real-time diagnostics.

[0005] Future initiatives to require zero emission vehicles appear to be taking us into a new regulatory paradigm where asymptotically smaller environmental benefits come at a very large incremental cost. Yet an "ultra low emission" certified vehicle can emit high emissions in limited extreme ambient and operating conditions or with failed or degraded components.

[0006] What is needed in the art is a power generation system which is compatible with conventional fuels and has essentially zero emissions and high efficiency.

SUMMARY OF THE INVENTION

[0008] The present invention is unique power generation systems and methods. In one embodiment, the system comprises: at least one SOFC capable of reforming fuel, said SOFC having a fuel side and an air side; a preheating device in fluid communication with said fuel side and said air side of said SOFC; an air supply in fluid communication with said preheating device; a fuel supply in fluid communication with said preheating device; and at least one energy conversion device in fluid communication with an SOFC effluent from said fuel side of said SOFC.

[0009] In another embodiment, the system comprises: at least one SOFC capable of reforming fuel, said SOFC having an intake fuel side, an intake air side, an effluent fuel side and an effluent air side; a preheating device in fluid communication with said fuel side and said air side of said SOFC; an air supply in fluid communication with said preheating device; a fuel supply in fluid communication with said preheating device; and at least one energy conversion device in fluid communication with an SOFC effluent from said fuel side of said SOFC.

[0010] One embodiment of a method of the present invention comprises: compressing an air stream to a first pressure; introducing fuel and said first compressed air to a preheating device; burning air in said preheating device to form a preheater effluent and a heated air stream; introducing said preheater effluent to a fuel side of a SOFC, said SOFC having an SOFC fuel effluent; and introducing said heated air stream to an air side of said SOFC,
Another embodiment of a method of the present invention comprises: compressing a heated air stream to a first pressure; vaporizing or atomizing a first portion of fuel in a preheating device to produce a preheater effluent; introducing preheater effluent to a fuel side of an SOFC, said SOFC having an SOFC fuel effluent; introducing said SOFC fuel effluent and said SOFC air effluent to a combustor to form a combustor effluent; and introducing said combustor effluent to a turbine.

Yet another embodiment of a method of the present invention comprises: compressing a heated air stream; vaporizing or atomizing fuel; introducing said fuel to a fuel side of an SOFC; applying a reverse potential to said SOFC such that the potential on the fuel side of said SOFC is negative; forming oxygen ions on said fuel side of said SOFC; migrating said oxygen ions from said fuel side to said air side of said SOFC to form an oxygen stream; and regenerating said catalytic converter by introducing said oxygen stream to said catalytic converter.

A further embodiment of a method of the present invention comprises: compressing a heated air stream to a first pressure; vaporizing or atomizing a first portion of fuel in a preheating device to produce a preheater effluent; introducing preheater effluent to a fuel side of a SOFC, said SOFC having an SOFC fuel effluent; introducing said first compressed air to an air side of said SOFC, said SOFC having an SOFC air effluent; and introducing said SOFC fuel effluent and said SOFC air effluent to an engine to produce an engine effluent; and introducing said engine effluent to a turbine.

These and other features and advantages of the present invention will be apparent from the following brief description of the drawings, detailed description, and appended claims and drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Referring now to the drawings, which are meant to be exemplary not limiting, and wherein like elements are numbered alike in the several Figures, mass flows are illustrated with solid lines, and power flows are illustrated with broken lines:

- Figure 1, is a schematic depiction of one embodiment of a system of the present invention which is designed for low and high total power output and start-up.
- Figure 2, is a schematic depiction of another embodiment of a system of the present invention which is designed for medium power output.
- Figure 3 is a schematic depiction of a further embodiment of a system of the present invention which uses a solid oxide fuel cell for oxygen generation.

DETAILED DESCRIPTION OF THE INVENTION

The present invention relates to power generation systems and methods for using the same. Generally, these systems may comprise one or more compressors, at least one solid oxide fuel cell ("SOFC"), an engine and/or an exhaust turbine, one or more heat exchangers, and optionally a catalytic converter, preheating device, electrical source, conventional connections, wiring, control valves, plasmatron, and a multiplicity of electrical loads, lights, resistive heaters, blowers, air conditioning compressors, starter motors, traction motors, computer systems, radio/stereo systems, and a multiplicity of sensors and actuators etc.

In one embodiment of the present invention, the system can be employed as the power source for a vehicle or another power conversion system requiring a high variable quantity of shaft and electrical power such as cogeneration of heat and electrical power, distributed electric infrastructure, and portable power systems, among others. The various flows and system controls are based upon the type of operation to be employed, e.g., start-up/cabin heating where quick heat up of the overall system is important, low power mode operation for conditions requiring less than about 10 kilowatts (kW) for a typical passenger vehicle, medium power mode operation for conditions requiring about 10 kW to about 80% of engine power, and high power mode operation for conditions requiring peak power (typically 100-150 kW). The powers given are typical for a larger passenger car. However, the systems of the present invention are suitable for use in applications of a few kilowatts up to several thousand kilowatts.

Start-Up/Cabin Heating Conditions

Start up conditions may cover the low and medium power modes (further described below) where the SOFC is rapidly brought to operating temperature and the engine is operated near the dilute, i.e. lean or with engine gas recycle, limit to nearly eliminate emissions prior to the catalyst reaching full operating temperature. In this mode the engine is fueled by reformate (SOFC effluent) generated by the SOFC (in systems where the SOFC is insulated and maintained
In one embodiment of the present invention, referring to Figures 1 and 2, the system shows air 1 entering the SOFC before the electrolyte is conductive.

This heated air 7 exits heat exchanger 120 and is directed into a second heat exchanger 115 where it is further heated, to temperatures of about 300°C or greater, and directed as stream 9 to compressor 100. From compressor 100, the compressed air 13 enters a preheating device 105 where at least a portion of the air is burned with at least a portion of the fuel entering the preheating device 105 as stream 33.

In the start up mode, the preheating effluent 15 is directed to the fuel side of SOFC 110, rapidly heating SOFC 110. Preheating effluent 15 is preferably combined with additional compressed air from line 17, reacting with oxygen in the air and further heating the SOFC. Meanwhile, additional compressed air 13, which has been heated in preheating device 105 passes through lines 18 and 19 to the air side of the SOFC, thereby heating it. Waste heat may be additionally removed from the preheating device and/or SOFC effluent with a gas/coolant heat exchanger for improved, rapid passenger compartment heating in winter conditions (not shown). In other normal power modes the preheating device 105 is turned off or reduced to a low power mode such that it acts to regulate the SOFC temperature and to vaporize or atomize and mix the inputs to the fuel side of the SOFC. From the SOFC 110, the SOFC fuel effluent 21 comprises greater than about 50 vol.%, hydrogen and carbon monoxide, with CO2, water and trace reaction products making up the balance, while the SOFC air effluent comprises oxygen depleted air 23. The SOFC effluent 21 and/or oxygen depleted air 23 may be supplied to the intake of exhaust side of the engine after cooling in a heat exchanger 115 allowing efficient dilute combustion with essentially zero emissions.

Oxygen Generation Mode

Referring to Figures 1 and 2, as is shown by electrical line 56, electricity can be directed into or removed from the SOFC. During normal system operation such as start-up/cabin heating, low power mode, medium power mode, and high power mode, electricity is produced by the SOFC which is removed via line 56 and directed via line 58 to an electrical source (motor/generator, battery, capacitor, or other device) for use in various areas of the system, or the electricity is directed out of the system via line 54 for an external use. In the oxygen generation mode, however, electricity is introduced to the SOFC via line 56 in order to establish a reverse electrical potential across the electrolyte within the SOFC.

Referring to Figure 3, the oxygen generation mode essentially comprises directing at least a portion of heated air 7 from heat exchanger 120, through compressor 100, and to preheating device 105, while the fuel 31 also enters preheating device 105 via line 33. A reverse electric potential is then applied across the electrolyte (negative potential on the fuel side and positive potential on the air side) within the SOFC 110 such that oxygen ions formed on the fuel side migrate across the electrolyte to the air side where they combine to form an oxygen stream. The oxygen stream can be pressurized and/or, partially or wholly, directed to a storage device (145) for future use such as: for emission control (catalyst heating or particulate trap regeneration), introduced into the engine in the start-up power mode, introduced into the engine effluent 35, and/or introduced into the air side of the SOFC, via line 19 (Figures 1 and 2) to boost its power output.

Low Power Mode Operation

In another embodiment of the present invention, referring to Figure 1, air 1 passes through optional heat exchanger 120 where it is heated from ambient temperature up to temperatures of about 100°C or greater. At least a portion of this heated air 7 exits heat exchanger 120 and is directed to compressor 100 where it is compressed prior to passing through preheating device 105. Meanwhile fuel 31 passes via line 33 to preheating device 105 where it is at least partially burned, and vaporized or atomized and directed as preheating effluent 15 into the fuel side of SOFC 110. Within the SOFC 110, oxygen in the air ionizes to O2⁻, producing electricity. The electricity is directed from the SOFC 110 via line 56, while the oxygen ions migrate across the ceramic electrolyte to the fuel side where they react with the vaporized fuel to form mostly water and carbon dioxide with less than about 2% by volume (vol.%) in total, of hydrogen, carbon monoxide, and by-products; thereby forming an oxygen depleted air stream 23 and a SOFC fuel effluent stream 21. Both the oxygen depleted air stream 23 and the SOFC fuel effluent stream 21 are cooled in heat exchanger 115, then the SOFC fuel effluent stream 21 and/or oxygen depleted air stream 23 are directed via lines 25 and 27, respectively, and 35 to turbine 130 to produce electricity and/or power for vehicle operation. From the turbine 130, the turbine effluent stream 39 preferably passes through a catalytic converter 135 to remove trace quantities of unburned and partially burned fuel from the exhaust stream. Then the exhaust gas 41 is preferably cooled in heat exchanger 120 and vented to the environment via line 43. Note that the engine 125 is off in the low power mode and electrical power is generated at very high efficiency for operation of the power train and vehicle accessories, with efficiencies of up to and exceeding about 60%.
Medium Power Mode Operation

In another embodiment of the present invention, referring to Figure 2, air 1 passes through optional heat exchanger 120. At least a portion of this heated air 7 exits heat exchanger 120 and is directed to compressor 100, preferably through preheating device 105 and via line 18, to the air side of the SOFC 110. Meanwhile at least a portion of fuel 31 passes via line 33 to preheating device 105 where it is vaporized or atomized and directed as preheating effluent 15 into the fuel side of SOFC 110. Within the SOFC 110, oxygen in the air ionizes to O\(^2\), producing electricity. The electricity is directed from the SOFC 110 via line 56, while the oxygen ions migrate across the ceramic electrolyte to the fuel side where they react with the vaporized fuel to form mostly hydrogen and carbon monoxide, typically about 20 vol.% to about 80 vol.% or more, with smaller amounts of vaporized fuel, water, carbon dioxide and other by-products comprising the balance; thereby forming an oxygen depleted air stream 23 and a SOFC fuel effluent stream 21N. Both the oxygen depleted air stream 23 and the SOFC fuel effluent stream 21N are cooled in heat exchanger 115 and the cooled SOFC effluent stream 25N, as well as cooled oxygen depleted air stream 27, compressed air 11, fuel 31, and optionally exhaust recirculation stream 37 (typically comprising up to about 20 vol.% of the engine effluent 35) enter the engine 125 where the fuel is burned. The remainder of the engine effluent 35 enters turbine 130 where electricity and/or power for vehicle operation are produced. The turbine effluent stream 39 preferably passes through a catalytic converter 135 to remove trace emissions of hydrocarbons, carbon monoxides, nitric oxide, and particulates prior to exiting the system, combining with the cooled oxygen depleted air stream 27, if any, or passing through heat exchanger 115.

High Power Mode Operation

Essentially, another embodiment of the present invention, the high power mode operation, is the same as the low power mode operation except the engine is operating at near peak power, the SOFC and engine are operating in parallel, and the engine is entirely fueled with unheated air and fuel. Referring to Figure 1, air 1 is directed to an optional compressor 100N where it is can be compressed prior to combining with at least a portion of fuel 31 and entering the engine 125 which produces engine effluent 35. Meanwhile at least a portion of fuel 31 passes via line 33 to preheating device 105 where it is vaporized or atomized, and partially burned, and directed as preheating effluent 15 into the fuel side of SOFC 110. Heated air 7, which is compressed in compressor 100, also passes through preheating device 105 prior to entering the air side of the SOFC 110.

Within the SOFC 110, oxygen in the air ionizes to O\(^2\), producing electricity. The electricity is directed from the SOFC 110 via line 56, while the oxygen ions migrate across the ceramic electrolyte to the fuel side where they react with the vaporized fuel to form mostly water and carbon dioxide, with smaller amounts of hydrogen, carbon monoxide, and by-products comprising the balance; thereby forming an oxygen depleted air stream 23 and a SOFC fuel effluent stream 21. Both the oxygen depleted air stream 23 and the SOFC fuel effluent stream 21 are cooled in heat exchanger 115, with a portion of the oxygen depleted air stream 23 optionally introduced after the exhaust turbine 130 into an optional two-stage catalyst 135 (e.g. a dual bed converter). Alternatively, the SOFC fuel effluent stream 21 and oxygen depleted air stream 23 are directed via lines 25 and 27, along with engine effluent 35, to the turbine 130. Within the turbine 130 electricity and/or power for vehicle operation are produced. The turbine effluent stream 39 then preferably passes through a catalytic converter 135 to remove any hydrocarbons, unburned fuel, nitric oxide, carbon monoxide and particulates from the exhaust stream prior to exiting the system, combining with the cooled oxygen depleted air stream 27, if any, or passing through heat exchanger 115.

As explained in the embodiments described above, the air is preferably compressed prior to introduction into the SOFC 110. Although two compressors are shown in Figures 1 and 2, it is understood that one or more compressors can be employed. The type of compressor is dependent upon the particular application. For example, with a conventional compressor capable of compressing to moderate pressures (up to about 3 atmospheres absolute pressure) typically employed in turbocharged engines useful for the embodiments shown in Figures 1 and 2, and with the pressure controlled to optimize the power output and efficiency of the SOFC and/or the engine as a system; with similar pressures preferably employed in the SOFC and the intake manifold in order simplify system design. For uses within a vehicle, the pressure can be up to or exceeding about 2 atmospheres (absolute pressure) with about 1 to about 2 atmospheres (absolute pressure) preferred. The compressor can be a mechanical device driven, for example, by direct connection to the exhaust turbine or by a mechanical supercharger, or can be operated independently via electricity or hydraulics.

SOFC employed with the present invention preferably possess greater fuel reformer capabilities than most conventional SOFC. For example, the SOFC is preferably designed with an enlarged reformer capability such that fuel is substantially dissociated into hydrogen and carbon monoxide even when the reformate carbon and hydrogen is not fully consumed at the electrodes. Improving the reformer capabilities of the SOFC can be obtained by adjusting the amount and type of catalyst employed, the surface area of the catalyst, the operating temperature of the SOFC (which is also catalyst dependent), and the flow rate of the air and fuel streams.

It is envisioned that multiple SOFCs can be employed, in series or in parallel, on the induction side of the engine,
or even with one or more SOFCs on the exhaust side of the engine. If located on the exhaust side of the engine, the SOFC would preferably receive fuel and engine effluent, and optionally air, in the fuel side of the SOFC, and air on the air side of the SOFC. The SOFC effluent (fuel side) could be directed through a turbine, catalytic converter, and/or heat exchanger (to heat the system intake air). It would be preferable to direct the engine effluent directly from the engine to the SOFC effluent to ensure the engine effluent had a sufficient temperature to operate the SOFC efficiently, i.e. about 600°C to about 800°C or so. The oxygen depleted air stream from the SOFC could pass through a turbine and/or catalytic converter.

[0030] The SOFC can employ conventional catalysts capable of producing a high hydrogen and carbon monoxide yield. Possible catalysts include noble metal-based catalysts and alloys thereof, among others, with rhodium-based catalysts and alloys thereof typically preferred due to their efficiency and resistance to sulfur and carbon poisoning.

[0031] Within the SOFC, the ionization of the oxygen produces electricity which can be directly utilized by the vehicle to power various electrical parts, including, but not limited to, lights, resistive heaters, blowers, air conditioning compressors, starter motors, traction motors, computer systems, radio/stereo systems, and a multiplicity of sensors and actuators, among others. Unlike conventional motor vehicles, the electricity produced by the SOFC is direct current which can be matched to the normal system voltage of the vehicle, thereby avoiding the requirements for devices such as diodes, voltage conversion and other losses, such as resistive losses in the wiring and in/out of the battery, associated with conventional vehicle systems and traditional hybrid electrical systems. This high efficiency electricity allows efficient electrification of the vehicle, including functions such as air conditioning and others, allowing weight, fuel economy and performance advantages compared to conventional hybrid electric mechanization and conventional internal combustion engine systems.

[0032] During start-up and for cabin heating, the SOFC can be operated at high adiabatic temperatures, e.g. up to about 1,000°C, subject to catalyst limitations, with typical operating temperatures ranging from about 600°C to about 900°C, and preferably about 650°C to about 800°C. In order to be introduced into the intake of an engine, however, the SOFC effluent, i.e. reformate, should be at a low temperature, i.e. a temperature below about 350°C, with a temperature of about 150°C to about 400°C preferred prior to entering the engine. Consequently, at least one heat exchanger is preferably employed to cool the SOFC effluent and conversely heat the air prior to entering the SOFC. Possible heat exchangers include conventional heat exchangers compatible with the environment within the system.

[0033] The fuel utilized in the system is typically chosen based upon the application, and the expense, availability, and environmental issues relating to the fuel. Possible fuels include conventional fuels such as hydrocarbon fuels, including, but not limited to, conventional liquid fuels, such as gasoline, diesel, ethanol, methanol, kerosene, and others; conventional gaseous fuels, such as natural gas, propane, butane, and others; and alternative or "new" fuels, such as hydrogen, biofuels, Fischer Tropsch, dimethyl ether, and others; and combinations thereof. The preferred fuel is typically based upon the type of engine employed, with lighter fuels, i.e. those which can be more readily vaporized, conventional fuels which are readily available to consumers, and high hydrogen to carbon ratio fuels generally preferred.

[0034] The other major component beside the SOFC which is typically employed by the system of the present invention to produce tractive power for a vehicle is the engine. Within the engine, air and fuel, and/or SOFC effluent are burned to produce energy. The engine can be any conventional combustion engine, such as an internal combustion engine, including, but not limited to, spark ignited and compression ignited engines, including, but not limited to, variable compression engines.

[0035] Similar to the engine, the turbine can be employed to recover energy from the engine effluent to produce tractive power and further to recover energy to operate the compressor(s) and preferably to generate electricity for various uses throughout the system and/or vehicle. The turbine employed can be any conventional turbine used for automotive or power generation energy conversion.

[0036] In a preferred embodiment, the exhaust turbine and compressor may be accelerated or decelerated by a motor, generator, or other device, to increase the compression (when required to increase the compression for optimal system performance) or to decrease compression (when excessive energy is available in the exhaust gases). For example, a high speed electrical machine can be linked to the turbine and compressor on a single shaft.

[0037] After passing through the turbine, the engine effluent preferably enters a catalytic converter in order to ensure extremely low, essentially zero emissions of hydrocarbons and nitric oxide, carbon monoxide, and particulates. The catalytic converter is typical of those used in automotive applications, including, but not limited to, particulate traps, dual bed converters, and those employing (1) noble metals and alloys thereof, such as platinum, rhodium and palladium catalysts and alloys thereof, among others and/or (2) particulate filtering and destruction.

[0038] Optional equipment which additionally may be employed with the present system include, but are not limited to, sensors and actuators, heat exchangers, (power mode) a battery, fuel reformer, burner, phase change material, thermal storage system, plamatron, an ultra capacitor, and/or a desulfurizer which may be employed if the fuel is rich in sulfur, or if the catalyst employed in the SOFC is particularly intolerant to sulfur, such as nickel-based catalysts, among other conventional equipment.

[0039] In contrast to conventional vehicles and even to prior art systems which employ fuel cells, the system of the
present invention does not require the use of a battery. Although a small battery relative to a battery utilized in a conventional vehicle operated at peak power train power will be employed as a buffer back-up system, it may even be very small relative to those used in other hybrid electric systems.

It has been discovered that utilization of the systems of the present invention can improve fuel efficiency. For example, when about 5.4 vol. fuel is reacted in a partial oxidation or catalytic reformer:

\[
C_4H_{12} + 3.5O_2 + 14N_2 \rightarrow 7CO + 6H_2 + 14N_2
\]

about 48 vol.% fuel is produced for introduction into the engine. When the system of the present invention is employed, however, using 11.8 vol.% fuel in the SOFC:

\[
2.5 O_2 \downarrow \\
C_4H_{12} + O_2 + 4N_2 \rightarrow 7CO + 6H_2 + 4N_2
\]

about 68 vol.% fuel is produced for introduction into the engine.

The various embodiments of the present invention provides advantages over the prior art in that they: (1) provide electrical power that is cheaper than shaft power in terms of fuel efficiency; (2) reduce or eliminate the need for batteries in a hybrid electric vehicle (the SOFC can operate with the engine off to supply electric accessories and modest tractive power (up to or exceeding about 10 kilowatts (kW) for a light duty passenger vehicle); (3) provide an efficiency benefit since conventional fuel reformers consume electricity, and the SOFC of the present invention performs the reforming function while producing electricity; (4) enable low to essentially zero emissions due to the ability to combust lean mixtures fuel the engine with reformate only (in start-up mode), and very dilute (lean or engine gas recycle) engine operation is possible in the medium power mode, thereby inhibiting the production of nitric oxides; (5) increase overall system efficiency, up to or exceeding about 60% at light load and about 45% at heavy load; and (6) are compatible with advanced combustion systems such as homogeneous charge compression ignition, "HCCI", where heated engine intake and extreme engine gas recycle rates are an advantage.

The SOFC can stay relatively small compared to total powertrain power so that a large efficiency benefit is possible for a light duty application (with a wide range of power output and large duty cycle of light load operation). The SOFC can then be miniaturized and mass produced while the conventional internal combustion engine can now meet the cost density and emissions requirements, and the power density by the consumer but at extremely low emission levels required by society.

The embodiments of the present system and method, although mostly described in relation to utilization within a vehicle, can be utilized in numerous applications, including, but not limited to: cogeneration of electrical power and heat (with liquid coolant loops added to recover waste heat for various applications such as space heating), distributed electric power generations, and portable power generation.

Claims

1. A power generation system, comprising:

(a) at least one solid oxide fuel cell (SOFC) (110) capable of reforming fuel, said SOFC (110) having a fuel side and an air side;
(b) a preheating device (105) in fluid communication with said fuel side and said air side of said SOFC (110);
(c) an air supply (1) in fluid communication with said preheating device (105) such that air is heated in said preheating device (105) and then introduced to said air side of said SOFC (110);
(d) a fuel supply (33) in fluid communication with said preheating device (105); and
(e) at least one energy conversion device in fluid communication with an SOFC effluent (21) from said fuel side of said SOFC (110);

characterized in that

fuel from said fuel supply (33) is burned, vaporized, atomized, or a combination thereof in said preheating device (105) and then introduced to said fuel side of said SOFC (110); and wherein said energy conversion device is a combustion engine (125) in fluid communication with said SOFC effluent (21) and said air supply (1), said engine (125) having an engine effluent (35) in fluid communication with a turbine (130); and wherein the power generation system further comprises:
- at least one heat exchanger (115) in fluid communication with said SOFC effluent (21) and said air supply (1) such that air passes through said heat exchanger (115) prior to introduction to said air side of said SOFC, and said SOFC effluent (21) passes through said heat exchanger (115) prior to introduction to said energy conversion device;
- at least one compressor (100) in fluid communication with said air supply (1) and said SOFC (110);
- a catalytic converter (135) having an inlet, wherein said inlet is in fluid communication with said energy conversion device.

2. A power generation system as in Claim 1, further comprising a second SOFC having a second fuel side and a second air side and a second SOFC effluent, wherein said second fuel side is in fluid communication with said engine effluent, said second air side in fluid communication with said air supply, and said second SOFC effluent is in fluid communication with said turbine.

3. A power generation system as in Claim 1, wherein said engine (125) is further in fluid communication with said fuel supply (31).

4. A method for operating a power generation system as claimed in claim 1, comprising the steps of:
   (a) compressing an air stream (1) to a first pressure by a compressor (100);
   (b) introducing fuel (31) and said first compressed air to a preheating device (105);
   (c) burning at least a first portion of said fuel in said preheating device (105) to form a preheater effluent (15) and to form a heated air stream (18,19);
   (d) introducing said preheater effluent (15) to a fuel side of a SOFC (110), said SOFC (110) having an SOFC fuel side effluent (21); and
   (e) introducing said heated air stream to an air side of said SOFC (110), said SOFC (110) having an SOFC air side effluent (23);

characterized in that the method further comprises the steps of
- heating said air stream (1) with said SOFC fuel side effluent (21);
- heating said air stream (1) with said SOFC air side effluent (23);
- vaporizing or atomizing a second portion of said fuel (31);
- burning SOFC fuel side effluent (21) with said SOFC air side effluent (23) in the combustion engine (125);
and
- directing engine effluent (35) through a turbine (130);
- directing a turbine effluent (39) through a catalytic converter (135); and
- heating said air stream (1) with catalytic converter effluent (41) within a heat exchanger (120) in fluid communication with the compressor (100).

5. A method for operating a power generation system as in Claim 4, further comprising compressing a portion of said air stream to a second pressure and introducing said second compressed air to said air side of said SOFC (110).

6. A method for operating a power generation system as in Claim 4, further comprising introducing at least a portion of said fuel (31) to said engine (125).

7. A method for operating a power generation system as in Claim 6, further comprising compressing a portion of said air stream (1) to a second pressure and introducing said second compressed air (17) to said fuel side of said SOFC (110).

8. A method for operating a power generation system as in Claim 4, further comprising introducing said SOFC fuel side effluent (21) and said SOFC air side effluent (23) to a heat exchanger (115) to heat a coolant.

9. A method for operating a power generation system as in Claim 4, further comprising introducing said preheater effluent (15) to a heat exchanger (115) to heat a coolant.

10. A method for operating a power generation system as in Claim 4, further comprising introducing an oxygen stream to said air side of said SOFC (110).
Patentansprüche

1. Ein Energieerzeugungssystem, das aufweist:

- (a) zumindest eine Festoxidbrennstoffzelle (SOFC - solid oxide fuel cell) (110), die zum Reformieren von Brennstoff fähig ist, wobei die SOFC (110) eine Brennstoffseite und eine Luftseite hat;
- (b) eine Vorwärmvorrichtung (105) in Fluidverbindung mit der Brennstoffseite und der Luftseite der SOFC (110);
- (c) eine Luftzufuhr (1) in Fluidverbindung mit der Vorwärmvorrichtung (105) derart, dass Luft in der Vorwärmvorrichtung (105) erwärmt wird und dann in die Luftseite der SOFC (110) eingeführt wird;
- (d) eine Brennstoffzufuhr (33) in Fluidverbindung mit der Vorwärmvorrichtung (105); und
- (e) zumindest eine Energieumwandlungsanlage in Fluidverbindung mit einem SOFC-Abfluss (21) von der Brennstoffseite der SOFC (110);

dadurch gekennzeichnet, dass

Brennstoff von der Brennstoffzufuhr (33) in der Vorwärmvorrichtung (105) verbrannt, vaporisiert, atomisiert wird oder eine Kombination daraus und dann in die Brennstoffseite der SOFC (110) eingeführt wird; und wobei

- die Energieumwandlungsanlage ein Verbrennungsmotor (125) in Fluidverbindung mit dem SOFC-Abfluss (21) und der Luftzufuhr (1) ist, wobei der Motor (125) einen Motor-Abfluss (35) in Fluidverbindung mit einer Turbine (130) hat; und wobei das Energieerzeugungssystem weiter aufweist:

- zumindest einen Wärmetauscher (115) in Fluidverbindung mit dem SOFC-Abfluss (21) und der Luftzufuhr (1) derart, dass Luft durch den Wärmetauscher (115) geht vor dem Einführen in die Luftseite der SOFC, und der SOFC-Abfluss (21) durch den Wärmetauscher (115) geht vor dem Einführen in die Energieumwandlungsvorrichtung;
- zumindest einen Kompressor (100) in Fluidverbindung mit der Luftzufuhr (1) und der SOFC (110);
- einen Katalysator (135) mit einem Einlass, wobei der Einlass in Fluidverbindung mit der Energieumwandlungsvorrichtung ist.

2. Ein Energieerzeugungssystem gemäß Anspruch 1, das weiter eine zweite SOFC mit einer zweiten Brennstoffseite und einer zweiten Luftseite und einem zweiten SOFC-Abfluss aufweist, wobei die zweite Brennstoffseite in Fluidverbindung mit dem Motor-Abfluss ist, die zweite Luftseite in Fluidverbindung mit der Luftzufuhr ist und der zweite SOFC-Abfluss in Fluidverbindung mit der Turbine ist.

3. Ein Energieerzeugungssystem gemäß Anspruch 1, wobei der Motor (125) weiter in Fluidverbindung mit der Brennstoffzufuhr (31) ist.

4. Ein Verfahren für einen Betrieb eines Energieerzeugungssystems gemäß Anspruch 1, das die Schritte aufweist:

- (a) Komprimieren eines Luftstroms (1) auf einen ersten Druck durch einen Kompressor (100);
- (b) Einführen von Brennstoff (31) und der ersten komprimierten Luft in eine Vorwärmvorrichtung (105);
- (c) Verbrennen zumindest eines ersten Teils des Brennstoffs in der Vorwärmvorrichtung (105), um einen Vorwärmer-Abfluss (15) zu bilden und um einen erwärmten Luftstrom (18, 19) zu bilden;
- (d) Einführen des Vorwärmer-Abflusses (15) in eine Brennstoffseite einer SOFC (110), wobei die SOFC (110) einen SOFC-Brennstoffseite-Abfluss (21) hat; und
- (e) Einführen des erwärmten Luftstroms in eine Luftseite der SOFC (110), wobei die SOFC (110) einen SOFC-Luftseite-Abfluss (23) hat;

dadurch gekennzeichnet, dass das Verfahren weiter die Schritte aufweist

- Erwärmen des Luftstroms (1) mit dem SOFC-Brennstoffseite-Abfluss (21);
- Erwärmen des Luftstroms (1) mit dem SOFC-Luftseite-Abfluss (23);
- Vaporisieren oder Atomisieren eines zweiten Teils des Brennstoffs (31);
- Verbrennen des SOFC-Brennstoffseite-Abflusses (21) mit dem SOFC-Luftseite-Abfluss (23) in dem Verbrennungsmotor (125); und
- Leiten eines Motor-Abflusses (35) durch eine Turbine (130);
- Leiten eines Turbine-Abflusses (39) durch einen Katalysator (135); und
- Erwärmen des Luftstroms (1) mit einem Katalysator-Abfluss (41) in einem Wärmetauscher (120) in Fluidverbindung mit dem Kompressor (100).
Revendications

1. Système de génération de puissance, comprenant :

(a) au moins une pile à combustible à oxyde solide (SOFC) (100) capable de reformer du carburant, ladite SOFC (110) ayant un côté combustible et un côté air ;
(b) un dispositif de préchauffage (105) en communication fluidique avec ledit côté combustible et ledit côté air de ladite SOFC (110) ;
(c) une alimentation d’air (1) en communication fluidique avec ledit dispositif de préchauffage (105) de telle façon que l’air est chauffé dans ledit dispositif de préchauffage (105) et est ensuite introduit vers ledit côté air de ladite SOFC (110) ;
(d) une alimentation de combustible (33) en communication fluidique avec ledit dispositif de préchauffage (105) ;
(e) au moins un dispositif de conversion d’énergie en communication fluidique avec un effluent de SOFC (21) depuis ledit côté combustible de ladite SOFC (110) ;

caractérisé en ce que

le combustible provenant de ladite alimentation de combustible (33) est brûlé, vaporisé, atomisé, ou une combinaison de ceux-ci, dans ledit dispositif de préchauffage (105) et est ensuite introduit vers ledit côté combustible de ladite SOFC (110) ; et dans lequel

ledit dispositif de conversion d’énergie est un moteur à combustion (125) en communication fluidique avec ledit effluent de SOFC (21) et ladite alimentation d’air (1), ledit moteur (125) ayant un effluent moteur (35) en communication fluidique avec une turbine (130) ; et dans lequel le système de génération de puissance comprend en outre :

- au moins un échangeur de chaleur (15) en communication fluidique avec ledit effluent de SOFC (21) et avec ladite alimentation d’air (1) de telle façon que l’air passe à travers ledit échangeur de chaleur (115) avant d’être introduit vers ledit côté air de ladite SOFC, et ledit effluent de SOFC (21) passe à travers ledit échangeur de chaleur (115) avant d’être introduit vers ledit dispositif de conversion d’énergie ;
- au moins un compresseur (100) en communication fluidique avec ladite alimentation d’air (1) et avec ladite SOFC (110) ;
- un convertisseur catalytique (135) ayant une entrée, ladite entrée étant en communication fluidique avec ledit dispositif de conversion d’énergie.

2. Système de génération de puissance selon la revendication 1, comprenant en outre une seconde SOFC ayant un second côté combustible et un second côté air et un second effluent de SOFC, dans lequel ledit second côté combustible est en communication fluidique avec ledit effluent moteur, ledit second côté air est en communication fluidique avec ledit effluent de SOFC (21).
fluidique avec ladite alimentation d’air de SOFC, et ledit second effluent de SOFC est en communication fluidique avec ladite turbine.

3. Système de génération de puissance selon la revendication 1, dans lequel ledit moteur (125) est en outre en communication fluidique avec ladite alimentation de combustible (31).

4. Procédé pour faire fonctionner un système de génération de puissance selon la revendication 1, comprenant les étapes consistant à :

(a) comprimer un flux d’air (1) à une première pression par un compresseur (100) ;
(b) introduire un combustible (31) et ledit premier air comprimé vers un dispositif de préchauffage (105) ;
(c) brûler au moins une portion dudit combustible dans ledit dispositif de préchauffage (105) pour former un effluent de préchauffage (15) et pour former un flux d’air chauffé (18, 19) ;
(d) introduire ledit effluent de préchauffage (15) vers un côté combustible d’une SOFC (110), ladite SOFC (110) ayant un effluent (21) du côté combustible de la SOFC ; et
(e) introduire ledit flux d’air chauffé vers un côté air de ladite SOFC (110), ladite SOFC (110) ayant un effluent (23) du côté air de la SOFC ;

caractérisé en ce que le procédé comprend en outre les étapes consistant à

- chauffer ledit flux d’air (1) avec ledit effluent (21) du côté combustible de la SOFC ;
- chauffer ledit flux d’air (1) avec ledit effluent (23) du côté air de la SOFC ;
- vaporiser ou atomiser une seconde portion dudit combustible (31) ;
- brûler ledit effluent (21) du côté combustible de la SOFC avec ledit effluent (23) du côté air de la SOFC dans le moteur à combustion (125) ; et
- diriger un effluent moteur (35) à travers une turbine (130) ;
- diriger un effluent de turbine (39) à travers un convertisseur catalytique (135) ; et
- chauffer ledit flux d’air (1) avec un effluent (41) du convertisseur catalytique à l’intérieur d’un échangeur de chaleur (120) en communication fluidique avec le compresseur (100).

5. Procédé pour faire fonctionner un système de génération de puissance selon la revendication 4, comprenant en outre l’étape consistant à comprimer une portion dudit flux d’air à une seconde pression et à introduire ledit second air comprimé vers ledit côté air de ladite SOFC (110).

6. Procédé pour faire fonctionner un système de génération de puissance selon la revendication 4, comprenant en outre l’étape consistant à introduire au moins une portion dudit combustible (31) vers ledit moteur (125).

7. Procédé pour faire fonctionner un système de génération de puissance selon la revendication 6, comprenant en outre l’étape consistant à comprimer une portion dudit flux d’air (1) à une seconde pression, et à introduire ledit second air comprimé (17) vers ledit côté combustible de ladite SOFC (110).

8. Procédé pour faire fonctionner un système de génération de puissance selon la revendication 4, comprenant en outre l’étape consistant à introduire ledit effluent (21) du côté combustible de la SOFC et ledit effluent (23) du côté air de la SOFC vers un échangeur de chaleur (115) pour chauffer un réfrigérant.

9. Procédé pour faire fonctionner un système de génération de puissance selon la revendication 4, comprenant en outre l’étape consistant à introduire ledit effluent de préchauffage (15) vers un échangeur de chaleur (115) pour chauffer un réfrigérant.

10. Procédé pour faire fonctionner un système de génération de puissance selon la revendication 4, comprenant en outre l’étape consistant à introduire un flux d’oxygène vers ledit côté air de ladite SOFC (110).
