Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

SPECIFICATION

[0001] The present invention refers to a device for the coupling of excavator teeth which is applicable to the buckets of excavating machines and, in general, to the active working edges of earth-moving machines of similar types.

[0002] Machines for civil engineering work which effect the removal of materials such as earth, rocks, etc., generally have active edges on the so-called buckets of the excavators, which are open receptacles of specific shape fixed to the supporting and travelling gear of the machine and which have the function of removing the mass of earth or earth and more or less loose stones, by means of their front edge, collecting in the bucket the materials which have been loosened, allowing them to be transferred to a vehicle for their transport to another site or simply for depositing the mass of earth and stones which has been removed, for its subsequent replacement, for example, in the case of the opening of a trench.

[0003] The buckets of excavators and the like suffer significant problems at the active edge because of the high degree of wear to which it is subjected by contact with the earth and stones, which have very abrasive characteristics. For this reason, it is necessary to equip the active edge of the excavator or similar machine with detachable teeth, which are removable components which bear the greater part of the wear by being in direct contact with the mass of earth and stones, and which are therefore parts which wear out very quickly. Said teeth, which are parts that can be exchanged fairly frequently, must combine characteristics which are to a certain extent contradictory, owing to the fact that, being parts which are changed frequently on excavating machines and the like, their price should be relatively low, so it is necessary to exclude mechanization of the teeth, which should be manufactured simply by casting or forging high strength steel. The other contradictory characteristic lies in the need for the mounting of the tooth on the tooth-carrier located at the active edge of the bucket for excavators or the like to be effected with sufficient adjustment to avoid as far as possible any play between the facing regions of the tooth-carrier and the tooth, since the occurrence, otherwise inevitable, of play in the said region results in an increase in the stresses at specific points of contact between the tooth and the tooth-carrier, which further increase the wear locally, in a process which may end in breakage of the parts and which involves changing the worn part, that is to say, the tooth, more or less frequently, according to how the above-mentioned wear phenomena can be controlled to a greater or lesser degree.

[0004] At present, many types of coupling between the teeth of excavators and the tooth-carriers are known, although all of them, given the contradictory conditions to be fulfilled and the hard work to which said components are subjected, exhibit defects with regard to what could be considered an ideal solution in terms of life of the tooth and avoidance of excessive wear on the tooth-carrier, enabling the latter to have an acceptably extended life.

[0005] US Patent 5561925 refers to a tooth assembly and retaining mechanism in which a nose portion matching with the socket of the tooth has parallel surfaces interconnected by a flat end surface.

[0006] US Patent 4625439 refers to an excavating tooth retaining means comprising a nose portion in which the tooth is fixed by means of a wedge in which the wear part lands directly against the holder.

[0007] However, none of said patents discloses the double inverted dovetail structure which characterizes the present invention.

[0008] In order to obtain an improvement in the characteristics of the couplings for excavator teeth, achieving rapidity of assembly and secure and durable coupling between the tooth and the tooth-carrier, the inventor of the present patent application has carried out investigations and tests which have resulted in a coupling for excavator teeth which has an improved performance in use.

[0009] The coupling for excavator teeth and the like which is the subject of the invention is of the type which has a projection on the front face of the tooth-carrier, directed substantially axially with respect to the longitudinal axis of the tooth-carrier, and in which the cross-section of the tooth coupling region has a cross-section decreasing from the starting region to the free end, being characterized by the combination of the areas of contact between the tooth-carrier and the tooth, and the positioning of the retaining cotter pin, so that a close coupling is obtained between the tooth and the tooth-carrier, giving rise to secure fastening, with many areas of contact between the two coupled components, for the purpose of reducing the local wear and with an arrangement of angles of the areas of contact such that the stresses produced on the tooth tend to produce greater wedging and matching of the tooth with the tooth-carrier.

In order to obtain this result, the area coupling the tooth with the tooth-carrier has a structure which is constituted basically by the joining of two reverse dovetail profiles, that is to say, the dovetail at the first end region being inverted compared to the dovetail at the second end region, corresponding to the starting region and the free end or point of the so-called "nose" of the tooth-carrier respectively. This is complemented by a slightly convex structure, above all of the upper area of junction between the base or start of the nose of the tooth-carrier and the end or projection thereof which has a uniform section. The area of junction of the upper curved part of the nose of the tooth-carrier with the base thereof has a narrow flat transverse region. The lateral faces of the nose of the tooth-carrier assume the form of facets, one of them corresponding to the front projection of constant
section and another to the lateral faces, which may be flat or gently curved with the convexity towards the outside.

[00010] With this arrangement the result is obtained that the nose of the tooth-carrier exhibits a much higher mechanical strength and, above all, in normal operation thereof no stresses are produced which tend to eject the tooth, which constitutes a recurrent problem of the currently known tooth-carriers. In particular, the slightly curved structure, with the convexity directed outwards, of the upper face of the nose of the tooth-carrier permits, in addition to a very efficient coupling between the tooth and the tooth-carrier, an increase in the cross-section of the nose of the tooth-carrier, and therefore a greater mechanical strength on the latter.

[00011] The device of the present invention is likewise characterized by a new type of cotter pin for retaining the tooth on the tooth-carrier, which is distinguished by its easy introduction and high resistance to removal, basically comprising a body of the cotter pin of flattened generally parallelepipedal structure, which on one of its intermediate sized faces has a wide rebate to which there is joined, by means of vulcanization of a special rubber, an insert carrying a small lateral projection with rounded transverse edges which is intended to be introduced into a seating of complementary shape of the tooth-carrier after its introduction.

[00012] For greater understanding there are appended, by way of explanatory but non-limiting example, drawings of a preferred embodiment of the present invention.

[00013] Figures 1 and 2 are views in elevation and in plan, respectively, of a tooth-carrier produced according to the present invention.

[00014] Figures 3 to 11 are sectional views through the section planes indicated in Figure 1.

[00015] Figures 12 and 13 are respective sections through the section planes indicated.

[00016] Figure 14 is a plan view of the assembly of tooth and tooth-carrier.

[00017] Figure 15 is a longitudinal section in a vertical plane of the assembly of tooth and tooth-carrier as indicated.

[00018] Figure 16 is a perspective view of the assembly of tooth and tooth-carrier when assembled.

[00019] As shown in the Figures, the coupling for excavator teeth which is the subject of the present invention has a fork-like part 1 intended for coupling with the edge of the excavator bucket and a region 2 that projects from the rear face 3 of the region 1 and is intended to receive the excavator tooth, indicated by 4 in Figures 12 and 14 and in Figures 15 and 16.

[00020] The region 1 for the coupling of the excavator to the bucket is fork-shaped with an upper arm 5 and a lower arm 6 which are separated by an indentation defined by flat areas 7 and 8 intended to receive the edge of the excavator bucket and which in plan have sections decreasing from the starting region 3 of the coupling 2 to the free end 9, the upper arm 5 also having flat lateral faces 10 and 11.

[00021] The tooth coupling projection 2 has a combination of successive regions, which is basically defined, as will be seen in Figures 3 to 11, by a structure constituted basically by two inverted dovetails, that is to say, the dovetail at the first end region being inverted compared to the dovetail at the second end region corresponding respectively to the starting area 12 of the tooth and to the end 13 of the projection 14 of the tooth-carrier, which correspondingly are complementary to the cavity of the tooth 4. The said projection 14, as shown by the sections provided, has a constant section throughout its length. For this reason, the lateral faces of the nose of the tooth-carrier 2 have a structure substantially formed by two facets gently differentiated so that one of the laterals corresponds respectively to the face 15 of the body of the nose of the tooth-carrier and the flat face 16 of the termination of constant section 14. The other lateral 17 has similar characteristics, having a wide indentation in a substantially vertical arrangement 18, which is intended to receive the cotter pin 19, which has been shown in greater detail in Figure 15.

[00022] The upper face 20 of the nose of the tooth-carrier has a generally curved shape with the convexity directed outwards, joining the inner end of the projection 14 to the body 1 of the tooth-carrier by means of a small flat area in the area of junction with the said body indicated by 21 in Figure 1 and also in Figure 13.

[00023] The lateral faces 15 and 17 may be flat or curved, with the convexity directed outwards.

[00024] The construction of the nose of the tooth-carrier with the shape indicated makes it possible to obtain a much higher strength thereon, at the same time eliminating the reactions of ejection of the tooth which customarily occur in the currently known mountings for excavator teeth.

[00025] As will be observed in Figures 12 and 15, the cotter pin 19 has a flattened straight, generally parallelepipedal structure, having on one of its minor sides a wide indentation 22 in which, by means of a vulcanized coating 23, there is effected the joining of a straight insert 24, carrying a lateral projection 25, provided with rounded edges, which is engaged in a recess of complementary shape of the nose of the tooth-carrier.

[00026] This arrangement of the cotter pin therefore makes possible both its easy introduction by axial compression in its groove and sufficient retention thereof in the nose of the tooth-carrier. Withdrawal is also facilitated by the existence of the joining part of vulcanized rubber.

[00027] By means of the arrangement which has been explained, the coupling device for excavator teeth which is the subject of the present invention makes it possible to fit the tooth with minimum play in all the coupling areas, as well as allowing numerous areas of contact in order to reduce local wear, and reduces the force components in the direction of ejection of the tooth with re-
pect to the tooth-carrier.

[0028] As it is obvious, this invention will cover the tooth holder as well as the tooth to be adapted to the same, which will have a form which is conjugated to the form of the mating tube holder, with cavities to receive the coupling device.

[0029] The characteristics of the cotter pin are also very advantageous, both as regards the ease of assembly and disassembly of the cotter pin and as regards the high holding force thereof.

Claims

1. Device for the coupling of excavator teeth, of the type which comprises a part (1) that can be coupled by one end to the edge of the bucket of the excavator or the like, and which at the other end has a projection (2) of decreasing section intended to receive the interchangeable tooth of the excavator which end portion has constant cross-section, characterized in that the nose (2) of the tooth-carrier has a general structure in which two end regions thereof, one corresponding to the area of junction of the said nose (2) with the body of the tooth-carrier and the other to the free end (13) of the tooth-carrier, assume in cross-section a dovetail structure, the dovetail at the first end region being inverted compared to the dovetail at the second end region, and the upper face (20) of junction of the said projection (14) with the base (3) of the tooth-carrier assuming a curved structure with the convexity directed outwards, the lateral faces of the nose of the tooth-carrier assuming a structure of flat facets, one of them carrying in proximity to the junction with the body of the tooth-carrier a substantially vertical indentation (18) for the coupling of the retaining cotter pin.

2. Device for the coupling of excavator teeth according to Claim 1, characterized in that in the area of junction between the upper curved face (20) of the nose of the tooth-carrier and the body of the latter there is provided a flat facet (21) arranged transversely.

3. Device for the coupling of excavator teeth according to Claim 1, characterized in that the cotter pin (19) for coupling between tooth (4) and tooth-carrier (2) has a rectangular generally parallelepipedal structure on one of the minor sides of which there is joined, on a wide indentation (22), by means of vulcanized rubber (23), a steel insert (24) from which protrudes a projection (25) capable of engaging in a recess of complementary shape of the corresponding lateral face of the indentation of the tooth-carrier body receiving the cotter pin, for the axial retention of the latter in its assembled position.

4. Device for the coupling of excavator teeth according to Claim 3, characterized in that the projection (25) for retaining the cotter pin (19) has rounded edges.

5. Tooth for excavating machines which has one cavity having interior complementary surfaces to all those exterior surfaces of the tooth-carrier of claims 1 to 4.

Patentansprüche

2. Gerät für die Kupplung von Baggergrabzähnen, gemäß Anspruch 1, dadurch gekennzeichnet, dass in der Verbindungsfäche zwischen der oberen gekrümmten Fläche (20) der Nase des Grabzahn trägers und dem Körper des Letzteren eine flache, diagonal angeordnete Seite (21) vorgesehen ist.

3. Gerät für die Kupplung von Baggergrabzähnen, gemäß Anspruch 1, dadurch gekennzeichnet, dass der Splint (19) zum Ankuppeln zwischen dem Grabzahn (4) und dem Grabzahnträger (2) eine rechtswinklige allgemein quaderförmige Struktur auf einer von den kleineren Seiten vorweist, an welche in einer breite Einkerbung (22) durch vulkanisierten Gummi (23) einen Stahleinsatz (24) verbunden ist, aus welchem eine Auskragung (25) ragt, die fähig ist zum Eingreifen in eine Vertiefung mit einer komplementären Form der entsprechenden seitlichen Fläche der Einkerbung des Grabzahnträgerkör-
pers, der den Splint aufnimmt, für das axiale Festhalten des Letzteren in seiner montierten Position.

5. Grabzahn für Bagger, welcher einen Hohlraum mit inneren zu den Außenflächen des Grabzahnträgers der Ansprüche 1 bis 4 komplementären Flächen aufweist.

Revendications

1. Dispositif pour l'accouplement de dents d'excavateur, du type qui comprend une pièce (1) qui peut s'accoupler par une extrémité au bord de la pelle de l'excavateur ou analogue, et qui à l'autre extrémité a une saillie (2) d'une section décroissante destinée à recevoir la dent amovible de l'excavateur, ladite portion d'extrémité a une section transversale constante, caractérisé en ce que le bec (2) du porteur de dent a une structure générale dans laquelle deux de ses régions d'extrémité, l'une correspondant à la zone d'union dudit bec (2) avec le corps du porteur de dent et l'autre correspondant à l'extrémité libre (13) du porteur de dent, adoptent en section transversale une structure en queue d'aronde, la queue d'aronde se trouvant à la première région d'extrême étant renversée, comparée avec la queue d'aronde se trouvant à la deuxième région d'extrême, et la face (20) supérieure d'union de ladite saillie (14) avec la base (3) du porteur de dent adoptant une structure courbée dont la convexité est orientée vers l'extérieur, les faces latérales du bec du porteur de dent adoptant une structure de facettes planes, l'une desquelles portant près de l'union avec le corps du porteur de dent une denture (18) essentiellement verticale pour l'accouplement du boulon de retenue.

2. Dispositif pour l'accouplement des dents d'excavateur selon la revendication 1, caractérisé en ce que dans la zone d'union entre la face (20) courbée supérieure du bec du porteur de dent et le corps de ce dernier, on a prévu une facette (21) plane disposée transversalement.

3. Dispositif pour l'accouplement des dents d'excavateur selon la revendication 1, caractérisé en ce que le boulon (19) pour l'accouplement entre la dent (4) et le porteur (2) de dent a une structure rectangulaire, généralement parallélépipédique sur une des petites faces duquel est uni, sur une large denture (22), au moyen de caoutchouc (23) vulcanisé, un insert (24) en acier à partir duquel est en vol à faux une saillie (25) susceptible de s'engager dans un évidemment à forme complémentaire de la face latérale complémentaire de la denture du corps du porteur de dent qui reçoit le boulon, pour la retenue axiale de ce dernier à sa position d'assemblage.

4. Dispositif pour l'accouplement des dents d'excavateur selon la revendication 3, caractérisé en ce que la saillie (25) pour retenir le boulon (19) a des bords arrondis.

5. Dent pour des machines excavatrices qui a une cavité ayant des surfaces intérieures complémentaires de toutes les surfaces extérieures du porteur de dent selon les revendications 1 à 4.
