Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

FIELD OF THE INVENTION

[0001] The present invention is directed to an intervertebral joint prosthesis. Specifically, the invention includes a device which is implanted in place of degenerated or absent intervertebral disc tissue, and tools and methods for implanting the same.

BACKGROUND OF THE INVENTION

[0002] In the treatment of diseases, injuries or malformations affecting spinal motion segments (which include two adjacent vertebrae and the disc tissue or disc space between them), and especially those affecting disc tissue, it has long been known to remove some or all of a degenerated, ruptured or otherwise failing disc. In cases in which intervertebral disc tissue is removed or is otherwise absent from a spinal motion segment, corrective measures are indicated to insure the proper spacing of the vertebrae formerly separated by the removed disc tissue. Commonly, the two vertebrae are fused together using transplanted bone tissue, an artificial fusion element, or other compositions or devices. Fusion of adjacent vertebrae is a procedure that is performed many tens of thousands of times each year in the United States and Canada.

[0003] There is increased concern in the spinal medical community, however, that the biomechanical rigidity of the intervertebral fusion may predispose neighboring spinal motion segments to rapid deterioration. See, e.g., B.H. Cummins, J.T. Robertson, and S.S. Gill, Surgical Experience With An Implanted Artificial Cervical Joint, J. Neurosurg. 88:943-948, 1998. For example, removal of the intervertebral disc and subsequent fusion of the C3-C4 vertebrae may spur deterioration of the C2-C3 and C4-C5 segments. A spinal fusion prevents the fused vertebrae from moving rotationally or translationally with respect to each other, as natural disc tissue permits. That lack of mobility may increase the stresses on adjacent spinal motion segments. Follow-up of patients undergoing a successful fusion may reflect an incidence of neighboring segmental disease as high as 20%, and indications are that 50% of fusion patients will continue to have complaints of pain. Several conditions have been found at spinal segments adjacent to a spinal fusion site, including disc degeneration, disc herniation, instability, spinal stenosis, spondylolisthesis and facet joint arthritis. Consequently, many patients may require additional disc removal and/or fusion procedures as a result of a spinal fusion. Alternatives to fusing a spinal motion segment therefore clearly have inherent advantages.

[0004] Several different types of intervertebral disc arthroplasty devices have been proposed for preventing collapse of the space between adjacent vertebrae, to reduce pain and to maintain stability and range of rotational motion between the vertebrae. For example, U.S. Patent No. 5,755,796 discloses a prosthesis for implantation in the disc space between adjacent vertebrae. The prosthesis has two elements, one being attached to the vertebra above the disc space, and the other being attached to the vertebra below the disc space. The lower element includes a hollow box frame having a spherical seat inside, and the upper element includes a spherically-shaped head that fits into the spherical seat. U.S. Patent No. 5,556,431 discloses a three-piece intervertebral disc endoprosthesis, in which two plates, each having a hollow in one side, are fixed to adjacent vertebrae so that the two hollows face each other across the disc space. The third element is a core having an outwardly rounded surface on each side that fits into the hollows in the vertebral plates. Similarly, U.S. Patent No. 5,684,296 discloses a prosthesis having two L-shaped members, each having curved sections between which a resilient disc body is placed.

[0005] U.S. Patent Nos. 5,782,832 and 5,683,465 disclose implants having two plate members anchored to adjacent vertebrae within the disc space. In U.S. Patent No. 5,782,832, the upper plate member has a rounded underside and the lower plate member has a hollowed top side to engage the underside of the upper plate member and allow rotation. In U.S. Patent No. 5,683,465, the plate members have a snap-fit ball and socket engagement allowing rotation. Other prosthetic intervertebral discs are also known. Some are composite components having metal and rubber or polymer inserts which are designed to replicate the characteristics and performance of the discs in separating and enabling movement of adjacent vertebrae with respect to each other. Other designs are more mechanical in nature, including springs or other damping mechanisms also designed to approximate the behavior of a normal disc.

[0006] The normal movement of vertebrae with respect to one another involves variable rotation and translation. These components of the movement are dictated by the shape and size of the individual vertebrae including the relative positions of the unconverted vertebra joints (in the cervical spine), the orientation of the facet joints and ligamentous constraints. In essence the axis of rotation for any two vertebrae is unique and during flexion or extension will shift, or translate.

[0007] The prior art describes disc prosthesis or joints that dictate a fixed axis of rotation that will not permit translation and will therefore prevent normal movement and tend to jam. The latter may lead to excessive stresses on the prosthesis leading to wear or failure or be transferred to adjoining motion segments provoking pain and/or accelerated degeneration. EP 0699426 discloses such a prosthesis that only permits rotation.

[0008] Further, many prior devices are relatively difficult to implant. Most are designed to be attached via integral anchors to the vertebral surface facing the intervertebral disc space. To implant such a device, the adjacent vertebrae must be spread substantially further apart than their normal distance from each other, so that the pros-
thesis can be maneuvered between the vertebrae and the anchors can be inserted into their respective vertebrae. Such an operation presents additional risk of injury to the vertebrae themselves from misplacement or scratching by the anchors, and to other tissues due to the spreading of the vertebra beyond its normal span.

Therefore, there remains a need for an intervertebral joint prosthesis allowing translational as well as rotational movement between implanted vertebrae, and which is easy to implant in a disc space. There is also a need for a method and instrumentation for implanting such an intervertebral joint prosthesis.

SUMMARY OF THE INVENTION

The present invention is directed to an intervertebral joint prosthesis having a ball component for engagement with a first vertebra and a trough component for engagement with a second vertebra adjacent to the first vertebra. The trough component includes a generally concave surface having a substantially flat portion. When the ball component and the trough component are engaged to their respective vertebrae, the ball component and the trough component engage each other in a ball-and-socket relationship permitting rotation and translation with respect to each other. Both the ball component and the trough component include a flat at one end of the component for engaging a vertebra.

The ball component includes a substantially spherically shaped convex portion which engages a substantially spherically shaped concave portion of the trough component, which concave portion also includes a flat portion. In one embodiment, the flanges of each component include holes through which bone screws can be fitted to attach the components to their respective vertebrae. The flanges may be configured to conform to the general shape of the human vertebra.

By permitting the ball component to slide or translate in the trough component the present invention enables both the axis of rotation and the degree of translation of the joint to be dictated by the anatomical constraints of the motion segment within an acceptable range.

The invention also contemplates a tool for use in implanting an intervertebral joint prosthesis, having an elongated handle portion and a prosthesis-engaging portion having elements which hold the one or more parts of the intervertebral joint prosthesis. In one embodiment, the prosthesis-engaging portion of the tool includes a central flange and/or a surface configured so that the intervertebral prosthesis or its parts are maintained in a predetermined orientation or spatial relationship. Where the intervertebral joint prosthesis includes apertures for accommodating bone screws, the prosthesis-engaging portion of the tool preferably includes associated apertures for drilling holes for bone screws and/or for holding the prosthesis to the tool.

The present invention also encompasses methodology for implanting a two-part intervertebral joint prosthesis which includes placing the prosthesis parts in a predetermined spatial relationship, inserting the parts into a disc space between two adjacent vertebrae so that one of the prosthesis parts abuts one of the vertebrae and the other of the prosthesis parts abuts the other of the vertebrae and so that the predetermined spatial relationship of the prosthesis parts is maintained, and fastening the parts to their respective vertebrae. Particular embodiments of the methodology include connecting the parts to an insertion tool in a predetermined relationship with each other, inserting the insertion tool into the body so that a portion of both parts of the prosthesis are in a disc space between adjacent vertebrae, and fastening each part of the prosthesis to a respective vertebra. A preferred embodiment of the fastening step includes drilling holes in the vertebrae through apertures in the prosthesis parts and a connected insertion tool and threading screws through the apertures and into the bone.

The present invention provides an intervertebral joint prosthesis, and tools and methods for implantation, which allows a normal range of translation and rotation between the adjacent vertebra to which the prosthesis has been fastened. The prosthesis is easy to implant via its flanges, obviating the need for distortion of the adjacent vertebrae to widen the disc space. The intervertebral joint prosthesis is also implanted with a predetermined orientation of the prosthesis or spatial relationship between its components, which reduces or eliminates the need for in vivo adjustment. The prosthesis of the present invention also has a low profile and a minimal number of parts. These and other advantages will be clear to one of ordinary skill in the art by reference to the drawings and to the detailed description herein.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a partial sectional view, showing a side view of one embodiment of the prosthesis of the present invention implanted between adjacent vertebrae shown in cross-section.

FIG. 1 a is a sectional view of the embodiment of the prosthesis illustrated in FIG. 1.

FIG. 2 is a front elevational view of an embodiment of the ball component of the prosthesis illustrated in FIG. 1.

FIG. 3 is a sectional view of the ball component illustrated in FIG. 2, taken along the line 3-3 and viewed in the direction of the arrows.

FIG. 4 is a sectional view of the ball component illustrated in FIG. 2, taken along the line 4-4 and viewed in the direction of the arrows.

FIG. 5 is a perspective view of an embodiment of the trough component of the prosthesis illustrated in FIG. 1.

FIG. 6 is a front elevational view of an embodiment
of the trough component of the prosthesis illustrated in FIG. 1.

FIG. 7 is a sectional view of the trough component illustrated in FIG. 5, taken along the line 7-7 in FIG. 6 and viewed in the direction of the arrows.

FIG. 8 is a sectional view of the trough component illustrated in FIG. 5, taken along the line 8-8 in FIG. 6 and viewed in the direction of the arrows.

FIG. 9 is a side elevational view of an embodiment of the ball component illustrated in FIG. 2.

FIG. 10 is a side elevational view of an embodiment of the trough component illustrated in FIG. 5.

FIG. 11 is a sectional view of the ball component illustrated in FIG. 9, taken along the line 11-11 and viewed in the direction of the arrows.

FIG. 12 is a sectional view of the trough component illustrated in FIG. 10, taken along the line 12-12 and viewed in the direction of the arrows.

FIG. 13 is a perspective view of one embodiment of the insertion tool of the present invention.

FIG. 14a is a side view of the embodiment of the insertion tool illustrated in FIG. 13.

FIG. 14b is a top view of the embodiment of the insertion tool illustrated in FIG. 13, rotated 90 degrees around the longitudinal axis illustrated in FIG. 14a.

FIG. 15a is a side view of an alternate embodiment of the insertion tool of the present invention.

FIG. 15b is a perspective view of one embodiment of the prosthesis of the present invention engaged to the prosthesis engaging portion of the embodiment of the insertion tool illustrated in FIG. 15a.

FIG. 16 is a perspective view of one embodiment of the prosthesis of the present invention engaged with the insertion tool illustrated in FIG. 13.

FIG. 17 is a side elevational view of an embodiment of the prosthesis of the present invention engaged with an embodiment of the prosthesis engaging surface of the insertion tool illustrated in FIG. 13.

DESCRIPTION OF THE PREFERRED EMBODIMENT

[0017] For the purposes of promoting an understanding of the principles of the invention, reference will now be made to the embodiment illustrated in the drawings and specific language will be used to describe the same. It will nevertheless be understood that no limitation of the scope of the invention is thereby intended, such alterations and further modifications in the illustrated device, and such further applications of the principles of the invention as illustrated therein, being contemplated as would normally occur to one skilled in the art to which the invention relates.

[0018] Referring generally to FIGS. 1-12, there is shown one embodiment of the intervertebral joint prosthesis 20 of the present invention. Prosthesis 20 includes a ball component 22 and a trough component 24 that are interengagable to form prosthesis 20. In an intervertebral disc space 28 between two adjacent vertebrae 26, 27, ball component 22 is fixed to one of the adjacent vertebrae (e.g. vertebra 26 in FIG. 1), and trough component 24 is fixed to the other adjacent vertebra (e.g. vertebra 27 in FIG. 1) so that the components are interengaged within at least a portion of intervertebral space 28.

[0019] Ball component 22 includes a generally convex surface 30 and in one embodiment an opposite substantially flat vertebra engaging surface 32. In a particular embodiment, generally convex surface 30 is substantially spherical in shape. In a specific embodiment, a wedge surface 33 is provided at one end of vertebra engaging surface 32, which allows easier insertion of ball component 22 into the disc space and impedes migration of ball component 22. A flange 34 is provided at one end of ball component 22 for attaching ball component 22 to a vertebra, and is preferably formed to have a low profile and bulk. In the embodiment in which ball component 22 includes wedge surface 33, flange 34 is at the opposite end of ball component 22 from wedge surface 33. Flange 34 includes a vertebra engaging surface 35.

[0020] In a particular embodiment of ball component 22, flange 34 includes one or more bone screw apertures 36, and in a specific embodiment, two bone screw apertures 36 are provided in a symmetric relationship through flange 34. In that specific embodiment, one or more bone screws 37 (FIG. 4) are threaded into the vertebra through one or more apertures 36 to fix ball component 22 to the vertebra. In the illustrated embodiment, an aperture 38 (FIGS. 2 - 3) is also provided through flange 34 for a locking screw 39 (FIG. 1). After ball component 22 is attached to the vertebrae using bone screw(s) 37, locking screw 39 is threaded into locking screw aperture 38 in flange 34, covering the heads of bone screw(s) 37 and preventing loosening of bone screw(s) 37 with respect to ball component 22. Additionally, the illustrated embodiment of ball component 22 includes indentations 40 for gripping ball component 22 by an insertion tool, as will be described further hereinafter. Preferably, indentations 40 are located at the base of flange 34, where flange 34 meets substantially flat vertebra engaging surface 32.

[0021] Flange 34 may be angled with respect to vertebra engaging surface 32 of ball component 22. In a particularly preferred embodiment, as illustrated in FIG. 3, the internal angle A between vertebra engaging surface 35 and vertebra engaging surface 32 is approximately 80 degrees. This angle has been found to provide a good fit with the anterior portion of the upper vertebra in a middle or lower cervical spinal motion segment, such as C4-C5. Ball component 22 can be constructed with a different angle between vertebra engaging surfaces 35 and 32 according to the vertebra to be implanted and the needs of patients. For example, for upper cervical spinal motion segments such as C2-C3, the internal angle between vertebra engaging surface 35 and vertebra engaging surface 32 may be somewhat more acute, in the range of 70 - 80 degrees. Flange 34 may also be slightly curved from side to side, as illustrated in FIG. 4. Such curvature is particularly useful for anterior place-
ment of prosthesis 20, as it approximates the lateral curvature of the anterior surface of the human vertebra.

[0022] Trough component 24, in the embodiment illustrated, is similar in many respects to ball component 22. Trough component 24 includes a generally concave surface 50, which generally concave surface 50 includes a substantially flat portion 52 (FIGS. 5 - 7). Opposite generally concave surface 50 is a vertebra engaging surface 54, which, in the illustrated embodiment, includes a wedge surface 55 similar to wedge surface 33 of ball component 22. Trough component 24 also includes a flange 56 and a flange vertebrae engaging surface 57 which are similar to flange 34 and flange vertebra engaging surface 35 of ball component 22.

[0023] As with a particular embodiment of ball component 22, the illustrated embodiment of flange 56 of trough component 24 includes at least one aperture 58 and preferably two symmetric apertures 58, each of which can accommodate a bone screw 59 (FIG. 8). In that embodiment, flange 56 may also include a lock screw aperture 60 and lock screw aperture 61, as described with respect to ball component 22. Additionally, trough component 24 in one embodiment includes indentations 62, which are similar in location and structure to indentations 40 of ball component 22. Flange 56 of trough component 24, in a preferred embodiment, is also angled with respect to vertebra engaging surface 54. In the illustrated embodiment, the internal angle B between flange vertebra engaging surface 57 and vertebra engaging surface 54 is approximately 95 degrees, which provides a good fit with the anterior portion of a lower vertebra of a middle or lower cervical spinal motion segment. As noted with respect to ball component 22, trough component 24 may be manufactured with a different angle between surfaces 57 and 54 according to the needs of the patient or other factors. For example, for upper cervical spinal motion segments, the angle between surfaces 57 and 54 may be between 90 and 100 degrees.

[0024] Referring now to FIGS. 5, 7 and 10, the generally concave surface 50 of trough component 24 is illustrated according to one embodiment of the present invention. Generally concave surface 50, in this embodiment, includes a substantially flat (in that it is cylindrical rather than spherical) surface 52 that is approximately centrally located on generally concave surface 50. In a specific embodiment, generally concave surface 50 includes substantially spherical surfaces 64 on both sides of substantially flat surface 52. Substantially flat surface 52 may be of any desired geometrical configuration, though in a currently preferred embodiment, substantially flat surface 52 is in the shape of a rectangle, analogous to a slot in generally concave surface 50, and is approximately parallel to flange 56. In a particular preferred embodiment of ball component 22 and trough component 24, the radius of generally convex surface 30 and of the spherical portion of generally concave surface 50 is approximately the same.

[0025] In use, ball component 22 and trough component 24 are attached to adjacent vertebrae so that a portion of components 22, 24 are within the disc space and engage each other to provide a ball-and-socket arrangement which permits rotation and translation of the components, and thereby the vertebrae to which they are fixed with respect to each other. To accomplish that, when prosthesis 20 is implanted generally convex surface 30 of ball component 22 engages generally concave surface 50 of trough component 24. When engaged with generally concave surface 50, generally convex surface 30 can rotate in any direction. When generally convex surface 30 is in contact with substantially flat portion 52 of generally concave surface 50, generally convex surface 30 can move along substantially flat portion 52 in translation, as well as rotate with respect to generally concave surface 50. In a specific embodiment of prosthesis 20, ball component 22 is an "upper" component and is fixed to the vertebra immediately above or superior to the disc space (i.e. the vertebra closer to the head). In that embodiment, trough component 24 is attached to the lower or inferior vertebra (i.e. the vertebra closer to the coccyx). Thus, with ball component 22 attached to one vertebra and trough component 24 attached to an adjacent vertebra so that generally convex surface 30 and generally concave surface 50 are engaged, prosthesis 20 permits the adjacent vertebrae to rotate and translate with respect to each other, providing a normal range of intervertebral joint motion.

[0026] The present invention also comprehends an insertion tool 70 for use in implanting joint prosthesis 20. As illustrated in FIGS. 13-17, insertion tool 70 in one embodiment includes an elongated handle portion 72 integral with or attached to an extension portion 74. A prosthesis-engaging portion 76 is attached at the end of extension portion 74. Prosthesis-engaging portion 76 includes prosthesis-engaging surface 78. Prosthesis-engaging surface 78, in the illustrated embodiment, includes a central separator flange 79. The illustrated embodiment of prosthesis-engaging portion 76 also includes a set of apertures 80. This embodiment of insertion tool 70 is intended for use with the embodiment of ball component 22 and trough component 24 having bone screw aperture(s) 36 and 58, respectively, and apertures 80 of prosthesis-engaging portion 76 are configured so as to communicate with aperture(s) 36 of ball component 22 and aperture(s) 58 of trough component 24. In that embodiment, apertures 80 are sized slightly larger than the head(s) of bone screw(s) 37, so that screw(s) 37 may be inserted through apertures 80 to fix components 22 and 24 of prosthesis 20 to their respective vertebrae without also fixing tool 70 thereto.

[0027] Prosthesis-engaging portion 76 of insertion tool 70 is also capable of retaining prosthesis 20 in engagement with prosthesis-engaging portion 76. The illustrated embodiment of prosthesis-engaging portion 76 also includes a pair of clips 82 on both sides of prosthesis-engaging portion 76. Clips 82 are designed to hold the embodiments of ball component 22 and trough component
prosthesis engaging surface 76. Cam screws 90 are then inserted into one aperture 80 on each side of separator flange 79. Ball component 22 and trough component 24, in the embodiment in which they include bone screw apertures 36 and 58, respectively, are engaged to prosthesis engaging surface 78 so that apertures 36 and 58 communicate with apertures 80 of prosthesis engaging portion 76. Cam screws 90 are then inserted into one of apertures 36 and one of apertures 58 to lock ball component 22 and trough component 24 to prosthesis engaging surface 76.

As illustrated in Figure 14a - 17, a particular embodiment of prosthesis-engaging portion 76 is configured to maintain ball component 22 and trough component 24 in a predetermined spatial relationship or neutral position so as to insure correct alignment and positioning of the components with respect to each other and with respect to disc space and vertebrae into which they are to be implanted. Separator flange 79 of prosthesis engaging portion 76 is configured to fit between and to insure the proper spacing between ball component 22 and trough component 24. Prosthesis-engaging surface 78 is angled so that, in cooperation with separator flange 79, prosthesis-engaging portion 76 holds ball component 22 and trough component 24 in a precise predetermined spatial relationship with each other. For example, in the embodiments described above in which vertebra engaging surfaces 32 and 35 of ball component 22 have an internal angle of 80 degrees, prosthesis engaging surface 78 will include a portion forming an internal angle of approximately 80 degrees with separator flange 79. Similarly, in the embodiment of trough component 24 in which vertebra engaging surfaces 54 and 57 have an internal angle of approximately 95 degrees, prosthesis engaging surface 78 will include a portion which forms an internal angle of approximately 95 degrees with separator flange 79. Ball component 22 and trough component 24 are thereby held for implantation together such that vertebra engaging surface 32 of ball component 22 and vertebra engaging surface 54 of trough component 24 are approximately parallel, and such that convex surface 30 is engaged with concave surface 50.

Insertion tool 70 has been described above primarily with respect to the embodiments of prosthesis 20 described herein. Nonetheless, one of ordinary skill in the art will appreciate that insertion tool 70 may be useful with other prostheses that must be held in a particular predetermined orientation, or that have parts that must be retained in a particular spatial relationship.

After an intervertebral disc is resected and/or the disc space is prepared, the intervertebral joint prosthesis 20 of the present invention may be implanted. Ball component 22 and trough component 24 of joint prosthesis 20 are placed in a predetermined relationship with each other, preferably by engagement to insertion tool 70 of the present invention or an equivalent tool. Components 22 and 24, held in a predetermined spatial relationship, are then inserted into the body so that vertebra engaging surfaces 32 and 54 are within the disc space. In the embodiments of components 22 and 24 that include a wedge surface 33 and 55, respectively, wedge surfaces 33 and 55 enable easier implantation of prosthesis 20 by forcing the adjacent vertebrae apart slightly, if necessary, as components 22 and 24 are advanced into the disc space. Once components 22 and 24 are inserted into the disc space, wedge surfaces 33 and 55 grip their respective vertebrae to impede or prevent migration of prosthesis 20.

As illustrated in Figure 14a -17, a particular embodiment of prosthesis-engaging portion 76 is configured to maintain ball component 22 and trough component 24 in a predetermined spatial relationship or neutral position so as to insure correct alignment and positioning of the components with respect to each other and with respect to disc space and vertebrae into which they are to be implanted. Separator flange 79 of prosthesis engaging portion 76 is configured to fit between and to insure the proper spacing between ball component 22 and trough component 24. Prosthesis-engaging surface 78 is angled so that, in cooperation with separator flange 79, prosthesis-engaging portion 76 holds ball component 22 and trough component 24 in a precise predetermined spatial relationship with each other. For example, in the embodiments described above in which vertebra engaging surfaces 32 and 35 of ball component 22 have an internal angle of 80 degrees, prosthesis engaging surface 78 will include a portion forming an internal angle of approximately 80 degrees with separator flange 79. Similarly, in the embodiment of trough component 24 in which vertebra engaging surfaces 54 and 57 have an internal angle of approximately 95 degrees, prosthesis engaging surface 78 will include a portion which forms an internal angle of approximately 95 degrees with separator flange 79. Ball component 22 and trough component 24 are thereby held for implantation together such that vertebra engaging surface 32 of ball component 22 and vertebra engaging surface 54 of trough component 24 are approximately parallel, and such that convex surface 30 is engaged with concave surface 50.

Insertion tool 70 has been described above primarily with respect to the embodiments of prosthesis 20 described herein. Nonetheless, one of ordinary skill in the art will appreciate that insertion tool 70 may be useful with other prostheses that must be held in a particular predetermined orientation, or that have parts that must be retained in a particular spatial relationship.

After an intervertebral disc is resected and/or the disc space is prepared, the intervertebral joint prosthesis 20 of the present invention may be implanted. Ball component 22 and trough component 24 of joint prosthesis 20 are placed in a predetermined relationship with each other, preferably by engagement to insertion tool 70 of the present invention or an equivalent tool. Components 22 and 24, held in a predetermined spatial relationship, are then inserted into the body so that vertebra engaging surfaces 32 and 54 are within the disc space. In the embodiments of components 22 and 24 that include a wedge surface 33 and 55, respectively, wedge surfaces 33 and 55 enable easier implantation of prosthesis 20 by forcing the adjacent vertebrae apart slightly, if necessary, as components 22 and 24 are advanced into the disc space. Once components 22 and 24 are inserted into the disc space, wedge surfaces 33 and 55 grip their respective vertebrae to impede or prevent migration of prosthesis 20.
screws have been threaded into the bone, clips 82 are disengaged from components 22 and 24 and insertion tool 70 is removed. Similarly, in the embodiment of insertion tool 70 illustrated in FIGS. 15a - 15b having cam screws 90, components 22 and 24 are attached to prosthesis-engaging portion 76 by locking cam screws 90 into one each of apertures 36 and 58. Holes are drilled through apertures 80 and apertures 36 and 58 not occupied by cam screws 90. After such holes are drilled, screws are threaded into such vertebra holes. The cam screws are then unlocked, the insertion tool 70 is removed and the remaining holes are drilled through apertures 36 and 58 in components 22 and 24. Bone screws 37 are threaded into the vertebrae through components 22 and 24 to complete the fixation of components 22 and 24 to their respective vertebrae.

The devices and methods of the present invention are currently believed to be most useful in repairing vertebral joints in the cervical region. Nevertheless, it is believed that the devices and methods of the present invention could also be useful in repairing other spinal motion segments as well.

In the embodiments of ball component 22 and trough component 24 which include a locking screw aperture 38 and 60, respectively, fixation of joint prosthesis 20 is completed by threading a locking screw (not shown) into apertures 38 and 60. When components 22 and 24 of joint prosthesis 20 are satisfactorily fixed, the operation may be concluded.

The attachment of components 22 and 24 to vertebrae has been primarily described through use of bone screws fixing the components to the vertebrae. It is understood that alternative attachment structures or methods may be used, such as by stapling or by applying adhesive to vertebra engaging surfaces 32, 35, 54 and/or 57, so long as components 22 and 24 are firmly fixed to their respective vertebrae so as to withstand the stresses inherent in continual rotational and translational movements. Further, joint prosthesis 20, as well as the bone screws or other structures used to implant them within the body, are preferably made of biocompatible materials such as stainless steel, titanium, or other known biocompatible materials or their equivalents. Insertion tool 70 can be made of any appropriate material, although stainless steel is preferred.

While the invention has been illustrated and described in detail in the drawings and foregoing description, the same is to be considered as illustrative and not restrictive in character, it being understood that only the preferred embodiment has been shown and described and that all changes and modifications that come within the scope of the invention are desired to be protected, said scope being defined by the appended claims.

Claims

1. An intervertebral joint prosthesis (20), comprising:

2. The intervertebral joint prosthesis of claim 1, wherein said generally convex surface (30) is substantially spherical.

3. The intervertebral joint prosthesis of claims 1 or 2, wherein said generally concave surface (50) includes a substantially spherical portion adjoining said substantially flat portion.

4. The intervertebral joint prosthesis of any of claims 1 to 3, wherein said generally concave surface includes two substantially spherical portions and said substantially flat portion is approximately centrally located with respect to said substantially spherical portions.

5. The intervertebral joint prosthesis of any of claims 1 to 4, wherein said substantially flat portion is substantially rectangular.

6. The intervertebral joint prosthesis of any of claims 3 to 5, wherein said substantially spherical portions of said generally concave surface and said substantially spherical portion of said generally convex surface have about the same radius.

7. The intervertebral joint prosthesis of any of claims 1 to 6, wherein said substantially flat portion is substantially parallel to said flange of said trough com-
8. The intervertebral joint prosthesis of any of claims 1 to 7, wherein said flange of said ball component and said flange of said trough component each include at least one aperture (36) for receiving a bone screw (37).

9. The intervertebral joint prosthesis of any of claims 1 to 8, wherein said flange of said ball component and said flange of said trough component each include two apertures for receiving bone screws, said apertures having non-planar longitudinal axes.

10. The intervertebral joint prosthesis of any of claims 1 to 9, wherein said ball component and said trough component each include an aperture (39) for receiving a locking screw (37) adjacent to said aperture for receiving a bone screw.

11. The intervertebral joint prosthesis of any of claims 1 to 10, wherein said flange of said ball component and said flange of said trough component both include a curved portion.

12. The intervertebral joint prosthesis of any of claims 1 to 11, wherein said ball component includes a surface opposite said generally convex surface for engaging the first vertebra, and said flange of said ball component forms an internal angle of about 80 degrees with said surface for engaging the first vertebra.

13. The intervertebral joint prosthesis of any of claims 1 to 12, wherein said trough component includes a surface opposite said generally concave surface for engaging the second vertebra, and said flange of said trough component forms an internal angle of about 95 degrees with said surface for engaging the second vertebra.

14. The intervertebral joint prosthesis of any of claims 1 to 13, further comprising an insertion tool (70) removably attached to said ball component and said trough component so that said components are maintained in a predetermined spatial relationship.

15. The intervertebral joint prosthesis of claim 14, wherein said insertion tool includes at least one clip (82) removably attaching said components to said insertion tool.

16. The intervertebral joint prosthesis of claims 14 or 15, wherein said insertion tool includes at least one cam screw (90) removably attaching said ball component to said insertion tool and at least one cam screw removably attaching said trough component to said insertion tool.

17. The intervertebral joint prosthesis of any of claims 14 to 16, wherein said insertion tool is removably attached to said flange of said ball component and said flange of said trough component.

18. The intervertebral joint prosthesis of any of claims 14 to 17, wherein said insertion tool includes a separator flange (79) configured to fit between said ball component and said trough component.

19. The intervertebral joint prosthesis of any of claims 1 to 18, wherein said substantially flat portion is configured to permit translational motion of said ball component in a direction transverse to said flange of said trough component.

20. The intervertebral joint prosthesis of any of claims 1 to 19, wherein said ball component includes a surface opposite said generally convex surface for engaging the first vertebra, said engaging surface including a wedge surface (33).

21. The intervertebral joint prosthesis of any of claims 1 to 20, wherein said trough component includes a surface opposite said generally concave surface for engaging the second vertebra, said engaging surface including a wedge surface (55).

22. The intervertebral joint prosthesis of any of claims 1 to 21, wherein said ball component includes a surface opposite said generally convex surface for engaging the first vertebra, said engaging surface of said ball component including a wedge surface, and wherein said trough component includes a surface opposite said generally concave surface for engaging the second vertebra, said engaging surface of said trough component including a wedge surface.

23. The intervertebral joint prosthesis of any of claims 1 to 22, wherein said substantially flat portion forms a part of a cylinder.

24. The intervertebral joint prosthesis of any of claims 1 to 23, wherein said ball component includes at least one indentation (40) adapted to accommodate an insertion tool.

25. The intervertebral joint prosthesis of any of claims 1 to 24, wherein said trough component includes at least one indentation (40) adapted to accommodate an insertion tool.

Patentansprüche

1. Zwischenwirbelgelenkprothese (20) mit:
   einer Kugelkomponente (22), die an einen er-
sten Wirbel (26) ansetzbar ist und eine allge-
mein konvexe Oberfläche (30) sowie an einem
Ende einen an den ersten Wirbel ansetzbaren
Flansch (34) aufweist; und
einer Pfannenkomponente (24), die an einen an
den ersten angrenzenden zweiten Wirbel (27)
ansetzbar und dadurch gekennzeichnet ist,
dass sie eine allgemein konkave Oberfläche
(50) mit einem im wesentlichen flachen Bereich
(52) sowie an einem Ende einen Flansch (56)
aufweist, der an den zweiten Wirbel ansetzbar
ist, wobei die konvexe Oberfläche an die kon-
vexe Oberfläche anlegbar ist und die allgemein
konvexe und die allgemein konkave Oberfläche
(30, 50) sich aneinander legen, wenn die Kugel-
komponente (22) und die Pfannenkomponente
an den ersten bzw. den zweiten Wirbel (26, 27)
angesetzt sind, und wobei beim Aneinanderlie-
gen der allgemein konvexen und der allgemein
konvexen Oberfläche (30, 50) die Kugel-
und die Pfannenkomponente (24) rotatorisch
und beim Aneinanderlegen der allgemein konvexen
Oberfläche (30) und des im wesentlichen ebe-
nen Bereichs der allgemein konkaven Oberflä-
che (50) die Kugelkomponente (22) und die
Pfannenkomponente (24) translatorisch relativ
zueinander bewegbar sind.

2. Zwischenwirbelgelenkprothese nach Anspruch 1, bei der die allgemein konvexe Oberfläche (30) im wesentlichen kugelförmig ist.

3. Zwischenwirbelgelenkprothese nach Anspruch 1 oder 2, bei der die allgemein konkave Oberfläche (50) einen im wesentlichen kugelförmigen Bereich aufweist der an den im wesentlichen flachen Bereich angrenzt.

4. Zwischenwirbelgelenkprothese nach Anspruch 1 bis 3, bei der die allgemein konkave Oberfläche zwei im wesentlichen kugelförmige Bereiche aufweist und der im wesentlichen flache Bereich bezüglich der im wesentlichen kugelförmigen Bereiche mittig liegt.

5. Zwischenwirbelgelenkprothese nach Anspruch 1 bis 4, bei der der allgemein flache Bereich im wesentlichen rechtwinklig ist.

6. Zwischenwirbelgelenkprothese nach einem der Ansprüche 3 bis 5, bei der die im wesentlichen kugelförmigen Bereiche der allgemein konkaven Oberfläche und der im wesentlichen kugelförmige Bereich der allgemein konvexen Oberfläche etwa den gleichen Radius aufweisen.

7. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 6, bei der der im wesentlichen flache Bereich im wesentlichen parallel zum Flansch der Pfannenkomponente liegt.

8. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 7, bei der der Flansch der Kugelkomponente und der der Pfannenkomponente jeweils mindestens eine Öffnung (36) zur Aufnahme einer Knochenschraube (37) enthalten.

9. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 8, bei der der Flansch der Kugelkomponente und der der Pfannenkomponente jeweils zwei Öffnungen zur Aufnahme von Knochenschrauben enthalten, wobei die Öffnungen nicht-planare Längssachsen aufweisen.

10. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 9, bei der die Kugel- und die Pfannenkomponente angrenzend an die Öffnung für eine Knochenschraube jeweils eine Öffnung zur Aufnahme einer Sicherungsschraube (39) enthalten.

12. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 11, bei der die Kugelkomponente gegenüber der allgemein konvexen Oberfläche eine Oberfläche aufweist, die an den ersten Wirbel anlegbar ist, und der Flansch der Kugelkomponente mit der genannten, an den ersten Wirbel anlegbaren Oberfläche einen Winkel von etwa 80 Grad einschließt.

13. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 12, bei der die Pfannenkomponente gegenüber der allgemein konkaven Oberfläche eine Oberfläche aufweist, die an den zweiten Wirbel anlegbar ist, und der Flansch der Pfannenkomponente mit der an den zweiten Wirbel anlegbaren Oberfläche einen Winkel von etwa 95 Grad einschließt.

14. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 13 weiterhin mit einem Einsetzwerkzeug (70), das lösbart an die Kugel- und die Pfannenkomponente so angesetzt ist, dass die Komponenten in einer vorbestimmten räumlichen Zuordnung gehalten werden.

15. Zwischenwirbelgelenkprothese nach Anspruch 14, deren Einsetzwerkzeug mindestens eine Spange (82) aufweist, die die Komponenten lösbart am Einsetzwerkzeug befestigt.

16. Zwischenwirbelgelenkprothese nach Anspruch 14 oder 15, deren Einsetzwerkzeug mindestens eine Nockenschraube (90), die die Kugelkomponente
lösbar am Einsetzwerkzeug befestigt, sowie mindestens eine Nokkenschraube aufweist, die die Pfannenkomponente lösbar am Einsetzwerkzeug befestigt.

18. Zwischenwirbelgelenkprothese nach einem der Ansprüche 14 bis 17, deren Einsetzwerkzeug einen Trennflansch aufweist, der zwischen die Kugel- und die Pfannenkomponente passend konfiguriert ist.

19. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 18, bei der der im wesentlichen flache Bereich so konfiguriert ist, dass er eine translatorische Bewegung der Kugelkomponente quer zum Flansch der Pfannenkomponente ermöglicht.

20. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 19, deren Kugelkomponente gegenüber der allgemein konvexen Oberfläche eine Oberfläche aufweist, die an den ersten Wirbel anlegbar ist und einen Keilflächenbereich (33) enthält.

22. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 21, deren Kugelkomponente gegenüber der allgemein konvexen Oberfläche eine Oberfläche aufweist, die an den ersten Wirbel anlegbar ist und einen Keilflächenbereich enthält, und deren Pfannenkomponente gegenüber der allgemein konkaven Oberfläche eine Oberfläche aufweist, die an den zweiten Wirbel anlegbar ist und einen Keilflächenbereich enthält.

23. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 22, deren im wesentlichen flacher Bereich Teil eines Zylinders ist.

24. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 23, deren Kugelkomponente mindestens eine Einkerbung (40) enthält, die ein Einsetzwerkzeug aufnehmen kann.

25. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 24, deren Pfannenkomponente mindestens eine Einkerbung (40) enthält, die ein Einsetzwerkzeug aufnehmen kann.

26. Zwischenwirbelgelenkprothese nach einem der Ansprüche 14 bis 25, deren Kugelkomponente gegenüber der allgemein konvexen Oberfläche eine Oberfläche aufweist, die mindestens eine Nokkenschraube aufweist, die die Pfannenkomponente lösbar am Einsetzwerkzeug befestigt.

28. Zwischenwirbelgelenkprothese nach einem der Ansprüche 14 bis 27, deren Einsetzwerkzeug einen Trennflansch aufweist, der zwischen die Kugel- und die Pfannenkomponente passend konfiguriert ist.

29. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 27, bei der der im wesentlichen flache Bereich so konfiguriert ist, dass er eine translatorische Bewegung der Kugelkomponente quer zum Flansch der Pfannenkomponente ermöglicht.

30. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 28, deren Kugelkomponente gegenüber der allgemein konvexen Oberfläche eine Oberfläche aufweist, die an den ersten Wirbel anlegbar ist und einen Keilflächenbereich (33) enthält.

31. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 29, deren Pfannenkomponente gegenüber der allgemein konkaven Oberfläche eine Oberfläche aufweist die an den zweiten Wirbel anlegbar ist und einen Keilflächenbereich (55) enthält.

32. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 30, deren Kugelkomponente gegenüber der allgemein konvexen Oberfläche eine Oberfläche aufweist, die an den ersten Wirbel anlegbar ist und einen Keilflächenbereich enthält, und deren Pfannenkomponente gegenüber der allgemein konkaven Oberfläche eine Oberfläche aufweist, die an den zweiten Wirbel anlegbar ist und einen Keilflächenbereich enthält.

33. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 32, deren im wesentlichen flacher Bereich Teil eines Zylinders ist.

34. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 33, deren Kugelkomponente mindestens eine Einkerbung (40) enthält, die ein Einsetzwerkzeug aufnehmen kann.

35. Zwischenwirbelgelenkprothese nach einem der Ansprüche 1 bis 34, deren Pfannenkomponente mindestens eine Einkerbung (40) enthält, die ein Einsetzwerkzeug aufnehmen kann.

Revendications

1. Prothèse d’articulation intervertébrale (20), comprenant:

- un composant formant bille (22) destiné à être mis en prise avec une première vertèbre (26), ledit composant formant bille comprenant une surface généralement convexe (30), et une colerette (34) au niveau d’une extrémité dudit composant formant bille pour être mis en prise avec la première vertèbre; et
- un composant formant creux (24) destiné à être mis en prise avec une seconde vertèbre (27) adjacente par rapport à la première vertèbre, caractérisé en ce que ledit composant formant creux comprend une surface généralement concave (50) avec une portion sensiblement plate (52), et une colerette (56) au niveau d’une extrémité dudit composant formant creux pour le mettre en prise avec la seconde vertèbre, ladite surface concave étant adaptée pour la mise en prise avec ladite surface convexe ; dans laquelle ladite surface généralement convexe (30) et ladite surface généralement concave (50) sont mises en prise ensemble lorsque ledit composant formant bille (22) et ledit composant formant creux sont mis en prise avec la première vertèbre (26) et la seconde vertèbre (27) respectivement, et la mise en prise de ladite surface généralement convexe (30) avec ladite surface généralement concave (50) permet une rotation dudit composant formant bille et dudit composant formant creux (24) l’un par rapport à l’autre, et la mise en prise de ladite surface générale-ment convexe (30) avec ladite portion sensiblement plate de ladite surface généralement concave (50) permet une translation dudit composant formant bille (22) et dudit composant formant creux (24) l’un par rapport à l’autre.

2. Prothèse d’articulation intervertébrale selon la revendication 1, dans laquelle ladite surface générale-ment convexe (30) est sensiblement sphérique.

3. Prothèse d’articulation intervertébrale selon la revendication 1 ou 2, dans laquelle ladite surface générale-ment convexe (30) comprend une portion sensiblement sphérique contiguë à ladite portion sensiblement plate.

4. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 3, dans laquelle ladite surface généralement convexe comprend deux portions sensiblement sphériques et ladite portion sensiblement plate est située de manière approximativement centrale par rapport auxdites portions sensiblement sphériques.
5. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 4, dans laquelle ladite portion sensiblement plate est sensiblement rectangulaire.

6. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 3 à 5, dans laquelle lesdites portions sensiblement sphériques de ladite surface généralement concave et de ladite portion sensiblement sphérique de ladite surface généralement convexe ont environ le même rayon.

7. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 6, dans laquelle ladite portion sensiblement plate est sensiblement parallèle par rapport à ladite collerette dudit composant formant creux.

8. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 7, dans laquelle ladite collerette dudit composant formant bille et ladite collerette dudit composant formant creux comprennent chacune au moins une ouverture (36) destinée à recevoir une vis à os (37).

9. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 8, dans laquelle ladite collerette dudit composant formant bille et ladite collerette dudit composant formant creux comprennent deux ouvertures destinées à recevoir des vis à os, lesdites ouvertures ayant des axes longitudinaux non planaires.

10. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 9, dans laquelle ledit composant formant bille et ledit composant formant creux comprennent chacun une ouverture destinée à recevoir une vis de blocage (39) adjacente par rapport à ladite ouverture destinée à recevoir une vis à os.

12. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 11, dans laquelle ledit composant formant bille comprend une surface opposée à ladite surface généralement convexe pour la mise en prise avec la première vertèbre, et ladite collerette dudit composant formant bille forme un angle interne d’environ 80 degrés avec ladite surface pour la mise en prise avec la première vertèbre.

13. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 12, dans laquelle ledit composant formant creux comprend une surface opposée à ladite surface généralement concave pour la mise en prise avec la seconde vertèbre, et ladite collerette dudit composant formant creux forme un angle interne d’environ 95 degrés avec ladite surface pour la mise en prise avec la seconde vertèbre.

14. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 13, comprenant en outre un outil d’insertion (70) attaché de manière amovible audit composant formant bille et audit composant formant creux de sorte que lesdits composants soient maintenus dans une relation spatiale prédéterminée.

15. Prothèse d’articulation intervertébrale selon la revendication 14, dans laquelle ledit outil d’insertion comprend au moins un étrier de fixation (82) attachant de manière amovible lesdits composants audit outil d’insertion.

16. Prothèse d’articulation intervertébrale selon la revendication 14 ou 15, dans laquelle ledit outil d’insertion comprend au moins une vis (90) de came attachant de manière amovible ledit composant formant bille audit outil d’insertion et au moins une vis de came attachant de manière amovible ledit composant formant creux audit outil d’insertion.

17. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 14 à 16, dans laquelle ledit outil d’insertion est attaché de manière amovible à ladite collerette dudit composant formant bille et ladite collerette dudit composant formant creux.

18. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 14 à 17, dans laquelle ledit outil d’insertion comprend une collerette de séparation (79) configurée de façon à s’ajuster entre ledit composant formant bille et ledit composant formant creux.

19. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 18, dans laquelle ladite portion sensiblement plate est configurée de façon à permettre un mouvement de translation dudit composant formant bille dans une direction transversale par rapport à ladite collerette dudit composant formant creux.

20. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 19, dans laquelle ledit composant formant bille comprend une surface opposée à ladite surface généralement convexe pour la mise en prise avec la première vertèbre, ladite surface de mise en prise comprenant une surface de coin (33).
21. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 20, dans laquelle ledit composant formant creux comprend une surface opposée à ladite surface généralement concave pour la mise en prise avec la seconde vertèbre, ladite surface de mise en prise comprenant une surface de coin (55).

22. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 21, dans laquelle ledit composant formant bille comprend une surface opposée à ladite surface généralement convexe pour la mise en prise avec la première vertèbre, ladite surface de mise en prise dudit composant formant bille comprenant une surface de coin, et dans laquelle ledit composant formant creux comprend une surface opposée à ladite surface généralement concave pour la mise en prise avec la seconde vertèbre, ladite surface de mise en prise dudit composant formant creux comprenant une surface de coin.

23. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 22, dans laquelle ladite portion sensiblement plate forme une partie d’un cylindre.

24. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 23, dans laquelle ledit composant formant bille comprend au moins une indentation (40) adaptée pour loger un outil d’insertion.

25. Prothèse d’articulation intervertébrale selon l’une quelconque des revendications 1 à 24, dans laquelle ledit composant formant creux comprend au moins une indentation (40) adaptée pour loger un outil d’insertion.
