NOTE: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
This invention relates to particles for use in powders. In particular, but not exclusively, the invention relates to particles for use in powder compositions for dry powder inhalers, especially particles of an amino acid for use in such powders.

Inhalers are well known devices for administering pharmaceutical products to the respiratory tract by inhalation. Inhalers are widely used particularly in the treatment of diseases of the respiratory tract.

There are a number of types of inhaler currently available. One device is the dry powder inhaler. The delivery of dry powder particles of pharmaceutical products to the respiratory tract presents certain problems. The inhaler should deliver the maximum possible proportion of the active particles expelled to the lungs, including a significant proportion to the lower lung, preferably at the low inhalation capabilities to which some patients, especially asthmatics, are limited. It has been found however, that, when currently available dry powder inhaler devices are used, in many cases only about 10% of the active particles that leave the device on inhalation are deposited in the lower lung. More efficient dry powder inhalers would give clinical benefits.

In order to increase the proportion of active particles which may be delivered to the lung, it has been proposed to add a further component to the powder. WO96/23485 describes the addition of an additive material to a powder for inhalation including carrier particles and active particles to improve the respirable fraction of the active material. A preferred additive material is leucine. WO97/03649 also describes the addition of leucine to powder compositions for dry powder inhalers, in which the compositions do not include carrier particles.

While the addition of the additive material to the compositions described in WO96/23485 and WO97/03649
give improved respirable fractions of the active components, it would clearly be desirable to make the effect of the
additive material still more beneficial.

WO96/3209 discloses a dispersible powdered composition for inhalation comprising an acid as an excipient,
an active agent and a dispersibility-enhancing amount of a water soluble protein. For example, a liquid formulation
of glycine, the active agent and the dispersing agent HSA (human serum albumin) are spray dried at an inlet temperature
of 115-125°C, resulting in particles with mass median aerodynamic diameters of 2.4 and 3.9. Isolated amino acid
particles are not disclosed.

According to the invention there are provided amino acid particles in which a sample of the particles has a
bulk density not more than 0.1 g cm⁻³.

The bulk density of the sample may be determined using the test described below.

A second aspect of the invention provides amino acid particles having a mass median aerodynamic diameter
(MMAD) of not more than 5µm. Reference is made above to the MMAD of the particles. Where the particles have a
low bulk density in accordance with the first aspect of the invention, the actual diameter of the particles can be relatively
large while the MMAD is still small enough for the desired aerodynamic characteristics of the particles.

Alternatively, the size distribution of the particles can be characterised by their volume mean diameter (VMD).
Advantageously, the VMD of the amino acid particles is not more than 10µm, preferably not more than 5µm.

As indicated above, it has been found that a particularly preferred amino acid is leucine.

It has been found that leucine having a VMD of less than 10µm has improved flow properties when added to powders. It is thought that the small particle size of the leucine is closely associated with a low bulk density. As described
above, such particles give improved flow properties.

Adantageously, the amino acid particles have a volume mean diameter not more than 5µm. That size is very
small for amino acid particles, in particular leucine particles.

In a third aspect of the invention, there is provided amino acid particles being in the form of flakes having a
thickness of not more than 0.5µm. Preferably the flakes have a thickness of not more than 100nm.

As indicated above, a preferred amino acid is leucine. Conventional leucine is in the form of flakes having a
thickness of at least 1µm and usually greater than 5µm. It has been found that, by reducing the thickness of the flakes,
the flow properties of the leucine particles is improved. It is thought that when the leucine is added to a powder the
thin leucine flakes act as “spacers” between the particles of the powder which improves its flow properties, in particular
the glidant properties.

In some cases, the particles of the third aspect of the invention will also have the desired MMAD (or VMD) of
the second aspect of the invention.

It has been found that the thin flakes of leucine in accordance with this further aspect of the invention generally
have a low density and improved flow properties

It has been found to be particularly advantageous for the leucine to be in the form of flakes having a thickness of
less than about 100nm.

It has been found that when, for example, the leucine flakes have been prepared using the spray drying
method described below, that they have a very small thickness of less than 100nm and a relatively large width. It has
been found that the flakes may become fractured during subsequent processing of the powder but that the beneficial
properties of the flakes are not substantially diminished. It is thought, therefore, that it is the very small thickness of
the flakes which gives their advantageous properties.

The aspect ratio of the flakes of amino acid can be considered to be the (width of the particles)/(thickness of
the particles). Advantageously the aspect ratio of the particles is at least 20, preferably at least 50.

Observation of the thickness of the flakes may be made by studying electron microscope (SEM) images of
the particles. For example, flakes may be mounted on an electron microscope stub with double sided tape and coated
with gold prior to examination on an electron microscope.

[0038] An alternative method for observing the dimensions of particles of the present invention is by sizing the particles on a microscope slide in a similar way to that described in British Pharmacopoeia 1973 (page 645, Ergotamine Aerosol Inhalation). In this case a small quantity of particles, for example 10 to 100mg, are dropped onto a microscope slide and examined under a microscope to assess the particle size of the deposit.

[0039] Where reference is made above to the shape and size of the particles, it should be understood that the reference is to the shape and size of the individual particles. Those particles may become agglomerated to form clusters of individual particles.

[0040] The amino acid of the first, second and third aspects of the invention will all be referred to below as "low-density amino acid" for ease of reference. Furthermore, where the amino acid is, for example, leucine, it will be referred to below as "low-density leucine". It should be understood, however, that the amino acid of the second and third aspects of the invention, for example, might not have the bulk density required in respect of the first aspect of the invention.

[0041] Where the amino acid is leucine, advantageously, the leucine is L-leucine. L-leucine is a naturally occurring form of leucine and is therefore preferred when the leucine is to be used in pharmaceutical compositions or other compositions that may enter the body.

[0042] Advantageously, the particles of low-density amino acid 5 include no further materials other than the amino acid. The particles may include a mixture of more than one amino acid.

[0043] According to the invention there is also provided a powder for use in a dry powder inhaler, the powder including active material and low-density amino acid particles.

[0044] The low-density amino acid is particularly advantageous for use in a powder for inhalation. There are several conventional additives that are included in powder compositions for inhalation to improve the flow properties of the powder. Many of the flow enhancing additives are, however, undesirable for inhalation because they are not particularly physiologically acceptable, for example silica. Amino acids are bio-compatible and relatively safe for inhalation.

[0045] It has been found that the addition of the low-density amino acid to a powder for inhalation can give an improved respirable fraction for the powder and/or improved emptying of the powder from the inhaler device on actuation of the inhaler.

[0046] Advantageously, the powder includes not more than 10% by weight of low-density amino acid based on the weight of the powder. For powders for inhalation, where the low density amino acid is added to the powder to improve the dispersal of the active particles, it has been found that while the addition of up to 10% by weight of the low-density amino acid can give improved powder performance, on the addition of about 20% by weight of the low-density amino acid, the benefit was reduced.

[0047] Where the low density amino acid is used as a flow aid, for example in powders other than for use in dry powder inhalers, it has been found that the low-density amino acid can be included in greater amounts without detrimental effects, for example the low-density amino acid may be present at a % by weight of 50%.

[0048] As indicated above, in some powders for inhalation, active material comprises substantially all of the powder. In some cases a small amount of additives, for example colorants and flavourings are included. Thus, the powder may include less than 10%, preferably less than 5% by weight of materials other than the active material and the amino acid, based on the weight of the powder. The active material may comprise not less than 60% by weight of the powder.

[0049] In other powders for inhalation, the powder includes other diluents, for example carrier particles as described above. Thus, the powder may further include particles of a diluent. The carrier particles may be present in an amount of at least 50%, preferably at least 90%, more preferably at least 95%, by weight based on the weight of the powder.

[0050] The diluent may have a particle size such that at least 90% by weight of the diluent particles have a particle size not more than 10µm. It has been found that the addition of fine particles of diluent gives improved respirable fraction.

[0051] Alternatively, the diluent may have a particle size such that at least 90% by weight of the diluent particles have a particle size not less than 50µm. Such particles are equivalent to the carrier particles described above and give improved flow properties to the powder.

[0052] It has been found that the addition of low-density amino acid gives improved respirable fraction of active particles when the powder is used in a dry powder inhaler. That is thought to be due to the improved flow properties of the powder leading to improved emptying of the powder from the inhaler device and/or improved dispersion of the active particles on actuation of the inhaler device.

[0053] Advantageously, the diluent has a fine particle portion having a particle size such that at least 90% by weight of the fine particle portion have a particle size not more than 10µm and a coarse particle portion having a particle size such that at least 90% by weight of the particles have a particle size not less than 50µm.

[0054] It will be understood that, unless it is clear to the contrary, the particle size or the diameter of the particles referred to is the aerodynamic diameter of the particles MMAD which may be measured by the method indicated below.

[0055] The fine particle portion and coarse particle portion may comprise the same material or different materials. Furthermore, each of the fine particle portion and the coarse particle portion may comprise a mixture of more than one material.
Advantageously, the powder includes not more than 10%, preferably not more than 5% by weight of the fine particle portion based on the weight of the powder. The fine particle portion of the diluent has a particle size that is advantageous for the delivery of the particles of the deep lung. It is generally advantageous for as little as possible of materials other than the active material to be transported to the deep lung.

According to the invention, there is also provided, a dry powder inhaler, the inhaler containing powder as described above.

The present invention also provides a method of preparing particles of amino acid, the method including the step of forming solid amino acid particles from a vapour or from a solvent, the method being such that the particles are formed while being suspended in a gas flow.

As indicated above, a conventional method of preparing amino acid, in particular leucine having a small particle size, is by milling the amino acid. Many amino acids, for example leucine are, however, soft materials and it is difficult to prepare leucine having a very small particle size in that way. Furthermore, the preparation of amino acid, for example leucine, using a milling technique increases the risk that there are contaminants or impurities in the amino acid. Furthermore, controlling the physical properties of powder produced by milling is difficult.

By preparing the amino acid by, for example, condensation from a vapour or by drying droplets of a solvent containing leucine, particles of amino acid having a small particle size can be more easily obtained. Furthermore, greater control of particle size and morphology is possible. The particles are produced in suspended form, reducing the risk of contamination. The particles produced suspended in a gas flow may be easily classified and separated by their aerodynamic properties.

The method of producing particles of the amino acid in accordance with the invention will depend on the physical nature of the amino acid. For example, leucine is an amino acid which sublimes and in one advantageous embodiment of the invention, leucine is condensed from leucine vapour to form the low-density particles according to the invention. Other amino acids decompose on heating. Such amino acids are therefore not suitable to be condensed from their vapour but may, for example, be prepared by spray drying in accordance with a further embodiment of the invention to form low density amino acid.

Advantageously, the amino acid is a material which sublimes.

In one aspect of the invention, the method of producing particles of amino acid includes the step of condensing amino acid vapour to form solid amino acid particles. That method is particularly desirable where the amino acid is to be co-condensed with another material. For example, where the amino acid is to be used in a powder including active material, the amino acid and the active material may be co-condensed together.

Advantageously, the particles of amino acid are formed by aerosol condensation. One amino acid which is particularly suited to preparation by that method is leucine.

Leucine sublimes at a temperature of about 220°C.

The method advantageously includes the steps of

a) heating an amino acid so that the amino acid forms amino acid vapour;

b) mixing the amino acid vapour with cool air to form a cloud of condensed amino acid particles; and

c) collecting the condensed particles.

Advantageously, the amino acid is passed through a furnace. The furnace may be a tube furnace. The initial amino acid particles are advantageously suspended from a fluidised bed by a flow of air. The material may then be carried in the gas flow into the tube furnace where it forms a vapour.

The condensed particles are advantageously collected in a cyclone and/or a filter or by precipitation.

Advantageously, the method includes the step of heating the amino acid particles to a temperature of at least 150°C at ambient pressure. It is envisaged that the pressure could be reduced to reduce the temperature required to form the amino acid vapour. The temperature to which the amino acid is heated will depend on the nature of the amino acid used and the temperature required to form a vapour of that amino acid.

According to a further aspect of the invention, in the method of producing particles of amino acid, droplets of amino acid in a solvent are dried in a spray drying step to form solid particles of amino acid, the method being such
that at least some of the amino acid sublimes during the spray drying.

Advantageously, the method includes the step of spray drying amino acid in a solvent.

Advantageously, the material to be dried comprises amino acid in solution, which is advantageously an aqueous solution.

Where the amino acid is one which sublimes, for example leucine, it is thought that it may be advantageous for some sublimation of the leucine to take place during the spray drying of the leucine to give the most advantageous morphology of the leucine particles produced. In such a case, advantageously, the spray drying method is such that at least some of the amino acid sublimes during the spray drying.

Conventional spray drying of the amino acid may produce large particles of amino acid which are generally spherical in shape. Where the amino acid is leucine, such particles may have a particle diameter of 40 \(\mu\)m or more. Such leucine particles produced by a spray drying method are described in Pharmaceutica Acta Helvetiae 70(1995) 133-139. Such particles have been found to be undesirable in that they do not give the desired properties for the low-density leucine.

Yamashita et al (Respiratory Drug Delivery J1 1998 p483) describes the use of spray-dried L-isoleucine particles as a hydrophobic carrier for inhalation. As indicated above, conventional spray drying of an amino acid is thought to produce particles having an undesirable morphology. The conventional spray dried particles would, however, have the properties desired in Yamashita having regard to the consideration of hygroscopicity.

WO 98/31346 describes the spray drying of materials for inhalation. The spray drying is said to diminish the tap density of the material by increasing particle surface irregularities and increasing particle porosity. As indicated above, it is believed that generally spherical porous particles do not give the desired properties for the materials of the present invention. In accordance with an aspect of the present invention, it has been found, surprisingly, that the herein described, unconventional, spray drying of an amino acid gives particles having a new and particularly desirable morphology.

To give the best properties for the leucine and other amino acids produced by spray drying, it has been found that the droplet size is advantageously very small. The droplet size used in Pharmaceutica Acta Helvetiae 70(1995) 133-139 is at least 30 \(\mu\)m. Most advantageously, the droplets dried in the method of the present invention have a mean size of not more than 10 \(\mu\)m, more preferably, not more than 5 \(\mu\)m.

It is also believed that a high temperature for the spray drying is of importance. In many cases, the temperature of the spray drying for the formation of advantageous particles in accordance with at least one aspect of the present invention will be significantly greater than that used in conventional spray drying techniques. For example, the inlet air temperature of the spray dryer may be greater than 150°C, preferably greater than 200°C at ambient pressure. The temperature of spray drying is of particular importance for materials which sublime and then condense to form the desired particle morphology. In such cases, advantageously the spray drying conditions are such that the desired sublimation takes place, at least part of the material, in the spray drying.

For both the first and second aspects of the invention in respect of the method, advantageously the method is such that the MMAD of the solid amino acid particles produced is not more than 10 \(\mu\)m. As indicated above, amino acid particles having a small particle size can be used as an additive to improve the flow properties of powders.

Advantageously, the method is such that the amino acid particles produced are low-density amino acid particles as described above.

The invention also provides amino acid obtainable by a method as described above.

For ease of reference, the amino acid particles prepared by a method as described above will also be referred to as "low-density amino acid". Also, where the low-density amino acid comprises, for example, leucine, the material will be referred to as a "low-density leucine". It should be appreciated, however, that the amino acid produced by the methods might not have, for example, the bulk density required in respect of the first aspect of the invention relating to the amino acid particles described above.

According to the invention, there is also provided a method of making a powder, the method including the steps of mixing low-density amino acid with active material.

As indicated above, the powder for may also include a diluent. In that case, advantageously, the method of producing the powder includes the step of mixing the low-density amino acid with active material followed by the step of mixing the low-density amino acid and active material with the diluent.

According to the invention, there is also provided the use of low-density amino acid in a powder to improve the flow properties of the powder.

Also provided is the use of low-density amino acid in a powder for use in a dry powder inhaler.

As indicated above, the use of the amino acid can improve the respirable fraction of the active material in the powder. It is thought that the respirable fraction is improved due to the improved dispersion of active material on actuation of the inhaler. Furthermore, where the powder also includes carrier particles, it is thought that the low-density amino acid promotes the release of the active particles from the surfaces of the carrier particles on actuation of the inhaler.
The active material referred to throughout the specification will be material comprising one or a mixture of pharmaceutical products. It will be understood that the term "active material" includes material that is biologically active, in the sense that it is able to decrease or increase the rate of a process in a biological environment. The pharmaceutical products include those products that are usually administered orally by inhalation for the treatment of disease such as respiratory disease, for example β-agonists, salbutamol and its salts or salmeterol and its salts. Other pharmaceutical products which could be administered using a dry powder inhaler include peptides and polypeptides such as DNase, leucotrienes and insulin.

The active material may include a β2-agonist, which may include salbutamol a salt of salbutamol or a combination thereof. Salbutamol and its salts are widely used in the treatment of respiratory disease. The active material may be salbutamol sulphate. The active material may be terbutaline, a salt of terbutaline, for example terbutaline sulphate, or a combination thereof. The active material may be ipatropium bromide.

The active material may include a steroid, which may be beclomethasone dipropionate or may be fluticasone. The active material may include a cromone, which may be sodium cromoglycate or nedocromil or its salts. The active material may include a leukotriene receptor antagonist.

The active material may include a carbohydrate, for example heparin.

**Bulk Density**

The bulk density (or poured density) of a material of the present invention is determined by the following method:

2g of the material is poured from weighing paper into a 100 cm³ graduated glass measuring cylinder in an upright position. Transfer of the material from the paper into the cylinder is made as rapidly as flow permits. The volume occupied by the poured powder in the cylinder is measured to the nearest 0.5 ml (bulk volume) and the weight of the powder is determined.

The bulk density of the material is calculated as the weight of the powder divided by the bulk volume.

An alternative method of measuring the bulk density is described in the European Pharmacopoeia 1997 2.9.15.

**Particle Size Distribution**

The particle size distribution was determined by low angle laser light scattering (Mastersizer X, Malvern Instruments, Malvern, UK). To approximately 5 mg of the sample to be analysed 10ml of dispersant was added (0.05% lecithin in cyclohexane). The sample suspension was sonicated for 30 seconds before analysis. The volume median diameter (VMD) and D(v,90) were determined. VMD is the diameter such that 50% of the particles by volume have a diameter less than the VMD. D(v,90) is the equivalent volume diameter at 90% cumulative volume.

**Mass Median Aerodynamic Diameter (MMAD)**

The MMAD of particles of a material of the present invention is determined using Multi-Stage Liquid Impinger in accordance with the method described in European Pharmacopoeia (supplement 1999) 2.9.18. (Aerodynamic assessment of fine particles) for powder inhalers.

**Example 1**

Spray-dried leucine was prepared by the following method.

L-leucine was spray-dried using a laboratory scale cocurrent spray-dryer (Model 191, Büchi, Switzerland). A solution of 1.0 % w/w L-leucine in water was prepared and atomised at a rate of 4.5 ml min⁻¹ using compressed air (600 1 hr⁻¹, 0.7mm nozzle). The droplets produced in the spray-dryer had a VMD of not more than about 10 µm. The inlet and outlet air temperatures of the spray dryer were 220°C and 150°C respectively.

The resulting powder was collected by cyclone separation transferred to glass vials and stored in a desiccator at room temperature over silica gel until used. The spray-dried L-leucine was a light, loose white powder. A microscopic examination of the spray-dried powder showed the presence of thin, flake-like particles.

The bulk density and particle size diameter (as VMD) were determined for the spray-dried leucine. Bulk density and VMD were determined by the method indicated above.

Table 1 shows the bulk density and particle size distribution for unprocessed L-leucine and for 5 batches of L-leucine spray-dried by the method of Example 1. It will be seen that the spray-dried leucine had bulk densities in the range 0.02 g cm⁻³ to 0.05 g cm⁻³.
Flow Properties

The flow properties of the L-leucine were determined by measuring the Carr’s Index of the powder. Spray-dried L-leucine was added to a powdered protein (BSA-maltodextrin 50:50).

Carr’s Index of a sample was determined by measuring the volume ($V_{\text{pour}}$) of weight ($W$) poured into a 250 cm$^3$ measuring cylinder and tapping the cylinder to obtain constant volume of the sample ($V_{\text{tap}}$). The poured density (bulk density) and the tap density are calculated as $W/V_{\text{pour}}$ and $W/V_{\text{tap}}$ respectively and Carr’s Index is calculated from the tapped density and the poured density by the formula:

$$\text{Carr’s Index (\%)} = \frac{\text{tapped} - \text{poured}}{\text{tapped}} \times 100$$

Table 2 shows the poured density (bulk density), tapped density and Carr’s Index.

### Example 2

Aerosolised leucine was prepared by the following method. Ground L-leucine was passed through a tube furnace. The L-leucine particles were suspended from a fluidised bed by a flow of air (about 20 l min$^{-1}$). The particles were carried in a gas flow into the tube furnace, which was at a temperature ranging from 150 to 300°C. The material sublimed. The vapour emitted from the furnace was mixed with cool air giving a cloud of condensed particles that were subsequently collected in a cyclone and membrane filter. The material collected was light and “fluffy” and includes particles in the form of thin flakes.

Powder blends were tested in a twin stage impinger (TSI) (European Pharmacopoeia 1997 2.9.18) to assess the efficiency of the delivery of the active particles to the lungs of a patient by an inhaler device. The TSI is a two-stage separation device used in the assessment of oral inhalation devices. Stage one of the apparatus including the upper impinger is a simulation of the upper respiratory tract. Stage two which includes the lower impinger is a simulation of the lower respiratory tract. The liquid used in both the upper and lower impinger is distilled water for the examples below.

In use, the inhaler is placed in a mouth of the TSI. Air is caused to flow through the apparatus by means of a pump, which is connected to stage two of the TSI. Air is sucked through the apparatus from the mouth, flows through upper tubing via the upper impinger and the lower tubing to the lower impinger where it bubbles through liquid and exits the apparatus via outlet pipe. The liquid in the upper impinger traps any particle with a size such that it is unable to reach stage two of the TSI. Fine particles, which are the particles able to penetrate to the lungs in the respiratory tract, are able to pass into stage two of the TSI where they flow into the lower impinger liquid. The pump is adjusted to give an air flow rate of 60 litres per minute in the apparatus.

The inhaler device is weighed. The mouthpiece of the inhaler device is connected to the mouth of the TSI, the inhaler is actuated to dispense a dose of the powder and the pump is switched on and timed for a period of ten seconds. The pump is then switched off and the inhaler is removed from the TSI, re-weighed and the amount of powder lost from the inhaler calculated.

The sections of the apparatus making up stage one of the TSI are washed into a second flask and made up to 250 ml with distilled water. The sections making up the second stage of the TSI are washed into a third flask and made up to 100 ml with distilled water.

The amount of active substance in each section of the TSI is measured for each test. The following method may be used.

The contents of the flasks containing the washings from the stages of the TSI are assayed using High Performance Liquid Chromatography (HPLC) analysis for the content of the active material and compared against standard solutions containing, for example, 0.5 µg ml⁻¹ and 1 µg ml⁻¹ of the active material.

The percentage of the active material in each stage of the TSI is calculated from the standard response for each test and the mean for the tests may be calculated to give an indication of the proportion of the active particles reaching the second stage of the TSI apparatus. The respirable fraction (fine particle fraction) is calculated as the percentage of the total amount of drug emitted from the inhaler device that reaches stage two of the TSI and gives an indication of the proportion of active particles which would reach the deep lung in a patient.

Multi-Stage Liquid Impinger

Powder blends were also tested in a Multi-Stage Liquid Impinger (MSLI) (European Pharmacopoeia 2.9.18.) as indicated above to assess the efficiency of the delivery of the active particles to the lungs of a patient by an inhaler device. The MSLI is a five-stage separation device used in the assessment of the fine particle characteristics of particle clouds generated using oral inhalation devices. Impaction stage 1 is the pre-separator and stage 5 is an integral filter stage. An impaction stage comprises an upper horizontal metal partition wall through which a metal inlet jet tube with its impaction plate is protruding.

In use, a suitable low resistance filter capable of quantitatively collecting the active material is placed in stage 5. The apparatus is assembled and connected to a flow system. For the examples below, a flow rate of 90 litres per minute was used.

20 ml of a solvent is dispensed into each of stages 1 to 4. With the pump running, the mouthpiece of the inhaler device is located in the mouthpiece adapter of the MSLI and the inhaler device is discharged.

The amount of active ingredient in each stage of the apparatus is determined, for example using the method described in European Pharmacopoeia 2.9.18. Thus the fine particle dose can be calculated.

For the following examples, the inhaler device used in the TSI and MSLI tests was the Monohaler (manufac-
Example 3

[0128] Powder blends were produced for testing in the TSI apparatus. The blends were produced by a standard sequence of the following steps:

i. Mixing in a Turbula mixer (a tumbling blender) for between 30 minutes and 1 hour at fast speed;
ii. Passing the blend through a series of 600µm, 420µm and 355µm aperture diameter sieves to improve mixing and to help break up stable agglomerates;
iii. Mixing the blend further in the Turbula mixer for between 30 minutes and 1 hour at a slow speed; and
iv. Filling the blend into gelatine capsules for use in the Monohaler, each capsule containing about 5 mg of the blend.

[0129] Various powder blends were prepared comprising an active material, salbutamol sulphate, and an additive material. Several of the blends included low-density leucine in accordance with the invention as the additive material. The low-density leucine was prepared by an aerosol method as described in Example 2 above. Other blends included no additive material or Aerosil (trade name of Degussa for colloidal silicon dioxide) or conventional milled leucine as the additive material to give comparative results. The percentages given for the amount of additive material in the blend is the percentage by weight of the additive based on the weight of the active material and additive material.

[0130] The % given for the amount of components in the blends is the % by weight of the component based on the weight of the powder blend.

The table shows that the addition of the low-density leucine improved the respirable fraction of the active material. Particularly good results were obtained where the percentage by weight of the low-density leucine was 1%.

[0131] Micronised salbutamol powder itself is difficult to handle, being cohesive and adhesive and significantly affected by static. The powder forms hard compact agglomerates and sticks to or jumps from surfaces due to electrostatic forces. The addition of 1% and 10% by weight of milled leucine improved the powder flow and handling performance of the salbutamol powder. The mixes including 1% and 10% by weight of the low-density leucine had significantly improved powder flow characteristics, with minimal adhesion to glass walls compared with the milled leucine mixes.

Example 4

[0132] The effect of the proportion of low-density leucine in the powder blend was determined by testing blends containing salbutamol sulphate and various percent by weight of low-density leucine. The effect of the method of blending was also investigated by combining the following mixing methods:

- HS - high shear mixing using a food processor having a metal blade
- LS - low shear mixing using a pestle and mortar and sieving
- S - sieving
- T - mixing in a tumbling blender (Turbula mixer)

The blends were tested using the TSI. The dose in each capsule of the powder blend was about 5 mg. Each test was repeated with a total of two capsules (a total of 10 mg of powder blend). The results are shown in Table 5.

[0133] The % given for the amount of components in the blends is the % by weight of the component based on the...
weight of the powder blend.

Thus it can be seen that the addition of low-density leucine gave a significant increase in the respirable fraction of the active material although, in each case, a large proportion of the active material remains in the device on actuation of the inhaler.

Salbutamol sulphate micronised powder is less difficult to handle than the salbutamol base powder but does exhibit cohesive and adhesive nature. While the addition of leucine gave some improvement in the powder flow and handling performance, the addition of the low-density leucine gave significantly improved powder flow and handling characteristics.

Example 5

Powder blends for inhalation comprising active material, low-density leucine and lactose diluent were tested using a multi-stage liquid impinger (MSLI) using a flow rate of 90 litres per minute. The blends were prepared by mixing the active material and low-density leucine using the method described in respect of Example 3 above. The active material used was salbutamol sulphate and the low-density leucine was prepared by aerosolisation as described in Example 2 above. The mixture was then mixed with lactose. Two grades of lactose were used. Sorbolac (400) comprises lactose fines having an effective particle diameter of 7µm and Lactochem comprises lactose having a particle size between 63µm and 90µm obtained by sieving. Capsules for testing were filled with between 20mg and 25mg of the powder blend.

The results of the MSLI tests are shown in Table 6. The % shown are the % by weight of the material based on the weight of the powder blend.

Thus it can be seen that the high respirable fraction is maintained on the inclusion of the lactose but the emptying of the capsule in improved compared with the blends which do not contain the lactose.

The use of the low-density leucine material has been described above in relation to its use in powders for pharmaceutical use, in particular in powders for inhalation for which the powder properties are of great importance.

The low-density leucine may be used, for example, in powder formulations for tabletting. The advantageous properties, in particular the flow properties, would improve the performance of the powder in the pressing of tablets.

The low-density amino acid may also be used as an additive in powders to be filled into capsules. The improved
flow and handling characteristics of the powders containing the low-density amino acid would give improved filling and emptying of the capsules.

[0142] There are several additive materials currently available and which are routinely added to powders to improve their flow properties, for example Aerosil (colloidal silica). A significant advantage of amino acids compared with, for example, silica is that amino acids are more pharmaceutically acceptable, in particular for inhalation into the lung.

[0143] A further advantage of some amino acids, in particular leucine, over silica is that, unlike silica, leucine dissolves in water to give a clear solution. It is envisaged, therefore, that the low-density amino acid, for example leucine, could advantageously be used in powders for use as diagnostic reagents for which the ability to form a clear solution may be essential.

[0144] It also envisaged that the low-density amino acids may find application in fields other than pharmaceutical field. For example, the low-density amino acid may be used in dry powders for fire suppressants, for example to improve the powder properties of powders in dry powder fire extinguishers.

Claims

1. Amino acid particles in which a sample of the particles has a bulk density not more than 0.1 g cm⁻³.

2. Amino acid particles according to claim 1, in which a sample of the particles has a bulk density not more than 0.05 g cm⁻³.

3. Amino acid particles having a mass median aerodynamic diameter (MMAD) not more than 5 µm.

4. Amino acid particles being in the form of flakes having a thickness of not more than 0.5 µm.

5. Amino acid particles according to claim 4 in which the flakes have a thickness of not more than 100 nm.

6. Amino acid particles according to any preceding claim, in which the amino acid is leucine.

7. A powder for use in a dry powder inhaler, the powder including active material and amino acid particles according to any of claims 1 to 6.

8. A powder according to claim 7, in which the powder includes not more than 20% by weight of amino acid based on the weight of the powder.

9. A powder according to claim 8, in which the powder includes not more than 10% by weight of amino acid based on the weight of the powder.

10. A powder according to claim 7 or claim 8, the powder further including particles of a diluent.

11. A powder according to claim 10, in which the diluent includes a crystalline sugar.

12. A powder according to claim 10 or claim 11, in which the diluent has a particle size such that at least 90% by weight of the diluent particles have a particle size not more than 10 µm.

13. A powder according to claim 10 or claim 11, in which the diluent has a particle size such that at least 90% by weight of the diluent particles have a particles size not less than 50 µm.

14. A powder according to claim 10 or claim 11, in which the diluent has a fine particle portion having a particle size such that at least 90% by weight of the particle of the fine particle portion have a particle size not more than 10 µm and a coarse particle portion having a particle size such that at least 90% by weight of the particles of the coarse particle portion have a particle size not less than 50 µm.

15. A powder according to claim 14, in which the fine particle portion and coarse particle portion comprise the same material.

16. A powder according to any of claims 14 or 15, in which the powder includes not more than 5% by weight of the fine particle portion based on the weight of the powder.
17. A powder according to any of claims 14 to 16, in which the powder includes not more than 95% by weight of the coarse particle portion based on the weight of the powder.

18. A dry powder inhaler, the inhaler containing powder according to any of claims 7 to 17.

19. A method of preparing particles of amino acid as claimed in any of claims 1 to 6, the method including the step of forming solid amino acid particles from a vapour or from a solvent, the method being such that the particles are formed while being suspended in a gas flow.

20. A method of preparing particles of amino acid as claimed in any of claims 1 to 6, the method including the step of condensing amino acid vapour to form solid amino acid particles.

21. A method according to claim 19 or claim 20, in which particles of amino acid are formed by aerosol condensation.

22. A method according to claim 20 or claim 21, in which the method includes the steps of
   a) heating the amino acid so that the amino acid forms a vapour;
   b) mixing the amino acid vapour with cool air to form a cloud of condensed amino acid particles; and
   c) collecting the condensed particles.

23. A method according to any of claims 20 to 22, the method including the step of heating the amino acid particles to a temperature of at least 150°C at ambient pressure.

24. A method of producing particles of amino acid, in which droplets of amino acid in a solvent are dried in a spray drying step to form solid particles of amino acid, the method being such that at least some of the amino acid sublimes during the spray drying.

25. A method according to claim 19, in which the method includes the step of spray drying to form solid particles of amino acid, and optionally involves drying droplets with a mean size of not more than 10 µm.

26. A method according to claim 25, in which the material to be dried comprises amino acid in solution.

27. A method according to claim 24 or claim 26, in which material to be dried comprises amino acid in aqueous solution.

28. A method according to claim 24 or 27 in which the droplets dried have a mean size of not more than 10 µm.

29. A method according to claim 24 or claim 27 when dependent upon claim 24, in which the method is such that the MMAD of the solid amino acid particles produced is not more than 10 µm.

30. A method according to claim 24, the method being such that the amino acid particles produced are amino acid particles according to any of claims 1 to 6.

31. Particles of amino acid obtainable by a method according to claim 24 or any of claims 27 to 29 when dependent upon claim 24.

32. A method of making a powder according to any of claims 7 to 17, the method including the steps of mixing amino acid according to any of claims 1 to 6 or claim 31 with active material.

33. A method of making a powder according to any of claims 10 to 17, the method including the step of mixing amino acid according to any of claims 1 to 6 or claim 31 with active material followed by the step of mixing the amino acid and active material with a diluent.

34. Use of particles of amino acid according to any of claims 1 to 6 or claim 31 in a powder to improve the flow properties of the powder.

35. Use of particles of amino acid according to any of claims 1 to 6 or claim 31 in a powder for use in a dry powder inhaler.
Patentansprüche

1. Aminosäureteilchen, wobei eine Probe der Teilchen eine Schüttdichte von nicht mehr als 0,1 g cm⁻³ aufweist.

2. Aminosäureteilchen nach Anspruch 1, wobei eine Probe der Teilchen eine Schüttdichte von nicht mehr als 0,05 g cm⁻³ aufweist.

3. Aminosäureteilchen, die einen mittleren aerodynamischen Massendurchmessers (MMAD) von nicht mehr als 5 µm aufweisen.

4. Aminosäureteilchen, die in der Form von Flocken vorliegen und eine Dicke von nicht mehr als 0,5 µm aufweisen.

5. Aminosäureteilchen nach Anspruch 4, wobei die Flocken eine Dicke von nicht mehr als 100 nm aufweisen.

6. Aminosäureteilchen nach einem der vorhergehenden Ansprüche, wobei die Aminosäure Leucin ist.

7. Pulver zur Verwendung in einem Trockenpulverinhalator, wobei das Pulver ein aktives Material und Aminosäureteilchen nach einem der Ansprüche 1 bis 6 enthält.

10. Pulver nach Anspruch 7 oder Anspruch 8, das zusätzlich Teilchen eines Verdünnungsmittels enthält.

11. Pulver nach Anspruch 10, wobei das Verdünnungsmittel einen kristallinischen Zucker enthält.

13. Pulver nach einem der Ansprüche 10 oder 11, wobei mindestens 90 Gew.-% der Verdünnungsmittelteilchen eine Teilchengröße von nicht weniger als 50 µm aufweisen.

15. Pulver nach Anspruch 14, wobei der Anteil feiner Teilchen und der Anteil grober Teilchen das gleiche Material umfasst.

17. Pulver nach einem der Ansprüche 14 bis 16, das, bezogen auf das Pulvergewicht einen Anteil von nicht mehr als 95 Gew.-% an groben Teilchen enthält.

18. Trockenpulverinhalator, der Pulver nach einem der Ansprüche 7 bis 17 enthält.

19. Verfahren zum Herstellen von Teilchen von Aminosäure nach einem der Ansprüche 1 bis 6, das den Schritt des Bildens fester Aminosäureteilchen aus einem Dampf oder aus einem Lösungsmittel umfasst, wobei das Verfahren derart ausgestaltet ist, dass die Teilchen durch Einbringen in eine Gasströmung gebildet werden.

22. Verfahren nach einem der Ansprüche 20 oder 21, wobei das Verfahren folgende Schritte umfasst:
   a) Erhitzen der Aminosäure, so dass sich ein Aminosäure-Dampf bildet;
   b) Mischen des Aminosäuredampfs mit kühler Luft unter Bildung einer Wolke kondensierter Aminosäureteilchen;
   c) Auffangen der kondensierten Teilchen.

23. Verfahren nach einem der Ansprüche 20 bis 22, das den Schritt des Erhitzens der Aminosäureteilchen auf eine Temperatur von mindestens 150°C bei Umgebungsdruck umfasst.

27. Verfahren nach einem der Ansprüche 24 oder 26, wobei das zu trocknende Material Aminosäure in wässriger Lösung umfasst.

28. Verfahren nach einem der Ansprüche 24 oder 27, wobei die getrockneten Tröpfchen eine Durchschnittsgröße von nicht mehr als 10 µm aufweisen.

29. Verfahren nach Anspruch 24 oder 27, sofern von Anspruch 24 abhängig, wobei der MMAD der hergestellten festen Aminosäureteilchen nicht mehr als 10 µm beträgt.

30. Verfahren nach Anspruch 24, wobei die hergestellten Aminosäureteilchen nach einem der Ansprüche 1 bis 6 ausgebildet sind.

32. Verfahren zum Herstellen eines Pulvers nach einem der Ansprüche 7 bis 17, welches die Schritte des Mischens von Aminosäure nach einem der Ansprüche 1 bis 6 oder Anspruch 31 mit aktivem Material umfasst.

34. Verwendung von Aminosäureteilchen nach einem der Ansprüche 1 bis 6 oder Anspruch 31 in einem Pulver zur Verbesserung der Fließeigenschaften des Pulvers.

35. Verwendung von Aminosäureteilchen nach einem der Ansprüche 1 bis 6 oder Anspruch 31 in einem Pulver zur Verwendung in einem Trockenpulverinhalator.

Revendications

1. Particules d'amino-acides, dans lesquelles un échantillon des particules présente une densité en masse qui n'est pas supérieure à 0,1 g/cm³.

2. Particules d'amino-acides selon la revendication 1, dans lesquelles un échantillon des particules présente une densité en masse qui n'est pas supérieure à 0,05 g/cm³.

3. Particules d'amino-acides ayant un diamètre aérodynamique médian en masse (MMAD) ne dépassant pas 5 µm.
4. Particules d'amino-acides ayant la forme de flocons ayant une épaisseur ne dépassant pas 0,5 µm.

5. Particules d'amino-acides selon la revendication 4, dans lesquelles les flocons ont une épaisseur ne dépassant pas 100 nm.

6. Particules d'amino-acides selon l'une quelconque des revendications précédentes, dans lesquelles l'amino-acide est la leucine.

7. Une poudre destinée à être utilisée dans un inhalateur de poudre sèche, la poudre comprenant une matière active et des particules d'amino-acides selon l'une quelconque des revendications 1 à 6.

8. Une poudre selon la revendication 7, dans laquelle la poudre ne contient pas davantage que 20 % en poids de l'amino-acide par rapport au poids de la poudre.

9. Une poudre selon la revendication 8, dans laquelle la poudre ne contient pas davantage que 10 % en poids de l'amino-acide sur la base du poids de la poudre.

10. Une poudre selon la revendication 7 ou la revendication 8, cette poudre contenant au surplus des particules d'un diluant.

11. Une poudre selon la revendication 10, dans laquelle le diluant comprend un sucre cristallin.

12. Une poudre selon la revendication 10 ou la revendication 11, dans laquelle le diluant a une taille de particules telle qu'au moins 90 % en poids des particules de diluant ont une taille de particules ne dépassant pas 10 µm.

13. Une poudre selon la revendication 10 ou la revendication 11, dans laquelle le diluant a une taille de particules telle qu'au moins 90 % en poids des particules de diluant ont une taille de particules ne dépassant pas 50 µm.

14. Une poudre selon la revendication 10 ou la revendication 11, dans laquelle le diluant comporte une portion en fines particules ayant une taille de particules telle qu'au moins 90 % en poids des particules de la portion en fines particules ont une taille de particules ne dépassant pas 10 µm et une portion en particules grossières ayant une taille de particules telle qu'au moins 90 % en poids des particules de la portion en particules grossières ont une taille de particules ne dépassant pas 50 µm.

15. Une poudre selon la revendication 14, dans laquelle la portion en particules fines et la portion en particules grossières sont constituées par la même matière.

16. Une poudre selon l'une quelconque des revendications 14 ou 15, dans laquelle la poudre ne contient pas davantage que 5 % en poids de portion en particules fines, sur la base du poids de la poudre.

17. Une poudre selon l'une quelconque des revendications 14 à 16, dans laquelle la poudre ne contient pas davantage que 95 % en poids de la portion en particules grossières, sur la base du poids de la poudre.

18. Un inhalateur à poudre sèche, cet inhalateur contenant une poudre selon l'une quelconque des revendications 7 à 17.

19. Une méthode de préparation de particules d'amino-acides, telle que revendiquée dans l'une quelconque des revendications 1 à 6, cette méthode comprenant l'étape consistant à former des particules solides d'amino-acides à partir d'une vapeur ou à partir d'un solvant, cette méthode étant telle que les particules sont formées alors qu'elles sont en suspension dans un courant gazeux.

20. Une méthode de préparation de particules d'amino-acides selon l'une quelconque des revendications 1 à 6, cette méthode comportant l'étape consistant à condenser de la vapeur d'amino-acides de manière à former des particules solides d'amino-acides.

21. Une méthode selon la revendication 19 ou la revendication 20, dans laquelle les particules d'amino-acides sont formées par condensation d'un aérosol.
22. Une méthode selon la revendication 20 ou la revendication 21, dans laquelle la méthode comporte les étapes consistant à :

a) chauffer l'amino-acide de manière telle que l'amino-acide forme une vapeur;

b) mélanger la vapeur d'amino-acide avec de l'air frais de manière à former un nuage de particules condensées d'amino-acides ; et
c) recueillir les particules condensées.

23. Une méthode selon l'une quelconque des revendications 20 à 22, cette méthode comportant l'étape consistant à chauffer les particules d'amino-acides jusqu'à une température d'au moins 150 °C à pression ambiante.

24. Une méthode de production de particules d'amino-acides, dans laquelle des gouttelettes d'amino-acides dans un solvant sont séchées dans une étape de séchage par pulvérisation, de manière à former des particules solides d'amino-acides, cette méthode étant telle qu'au moins une certaine quantité de l'amino-acide se sublime au cours du séchage par pulvérisation.

25. Une méthode selon la revendication 19, dans laquelle la méthode comporte l'étape consistant en un séchage par pulvérisation de manière à former des particules solides d'amino-acides et facultativement à sécher des gouttelettes avec une taille moyenne ne dépassant pas 10 µm.

26. Une méthode selon la revendication 25, dans laquelle la matière à sécher consiste en un amino-acide en solution.

27. Une méthode selon la revendication 24 ou la revendication 26, dans laquelle la matière à sécher consiste en un amino-acide en solution aqueuse.

28. Une méthode selon la revendication 24 ou la revendication 27, dans laquelle les gouttelettes séchées ont une taille moyenne ne dépassant pas 10 µm.

29. Une méthode selon la revendication 24 ou la revendication 27, quand elle dépend de la revendication 24, dans laquelle la méthode est telle que le MMAD des particules solides d'amino-acides produites ne dépassent pas 10 µm.

30. Une méthode selon la revendication 24, la méthode étant telle que les particules d'amino-acides produites sont des particules d'amino-acides selon l'une quelconque des revendications 1 à 6.

31. Particules d'amino-acides obtenues par une méthode selon la revendication 24 ou l'une quelconque des revendications 27 à 29 quand elles sont dépendantes de la revendication 24.

32. Une méthode de fabrication d'une poudre selon l'une quelconque des revendications 7 à 17, cette méthode comportant les étapes consistant à mélanger l'amino-acide selon l'une quelconque des revendications 1 à 6 ou la revendication 31 avec une matière active.

33. Une méthode de fabrication d'une poudre selon l'une quelconque des revendications 10 à 17, cette méthode comportant l'étape consistant à mélanger l'amino-acide selon l'une quelconque des revendications 1 à 6 ou la revendication 31 avec une matière active puis l'étape consistant à mélanger l'amino-acide et la matière active avec un diluant.

34. Utilisation des particules d'amino-acides selon l'une quelconque des revendications 1 à 6 ou la revendication 31 dans une poudre pour améliorer les propriétés d'écoulement de la poudre.

35. Utilisation des particules d'amino-acides selon l'une quelconque des revendications 1 à 6 ou la revendication 31 dans une poudre en vue d'être utilisée dans un inhalateur à poudre sèche.
