Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Field of the Invention

[0002] The present invention relates to the use of synergistic amounts of glyburide and milrinone for the manufacture of a medicament for treating non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance. The present invention also relates to kits and pharmaceutical compositions that comprise synergistic amounts of 1) glyburide; and 2) milrinone. The present invention also relates to kits and pharmaceutical compositions that comprise synergistic amounts of 1) glyburide; 2) milrinone; and 3) an additional compound useful for the treatment of non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance.

Background of the Invention

[0003] In spite of the early discovery of insulin and its subsequent widespread use in the treatment of diabetes, and the later discovery of and use of sulfonylureas, biguanides and thiazolidenediones, such as troglitazone, rosiglitazone or pioglitazone, as oral hypoglycemic agents, the treatment of diabetes can be improved.

[0004] A group of compounds that stimulate insulin secretion and stimulate de novo synthesis of insulin are the cAMP phosphodiesterase type 3 inhibitors. It is believed that cAMP phosphodiesterase type 3 inhibitors act to increase insulin secretion by increasing intracellular levels of cAMP in pancreatic β-cells in the islet of Langerhans. In contrast, sulfonylureas act on the K+ ATP channels of pancreatic β-cells in the islet of Langerhans. Moreover, cAMP phosphodiesterase type 3 is known to exist in two forms: type A and type B. Type A cAMP phosphodiesterase 3 is associated with cardiac tissue and with platelets, and type B is associated with liver and adipose tissue, and β-cells in the pancreas.

[0005] In addition to sulfonylureas, which stimulate insulin secretion by acting on the K+ ATP channels, a group of non-sulfonylureas are known to stimulate insulin secretion by acting on K+ ATP channels. Examples of such non-sulfonylurea insulin secretagogues include nateglinide and repaglinide.

[0006] The present invention provides an improved method of treating non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance using a synergistic amount of: 1) glyburide; and 2) milrinone.

[0007] The present invention also relates to kits and pharmaceutical compositions that comprise: 1) glyburide; and 2) milrinone.

[0008] In addition, the present invention relates to kits and pharmaceutical compositions that comprise: 1) glyburide; 2) milrinone; and 3) an additional compound useful for the treatment of non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance.

Summary of the Invention

[0009] The present invention provides the use of a synergistic amount of: 1) glyburide; and 2) milrinone for the manufacture of a medicament for treating non-insulin dependent diabetes mellitus,

[0010] Also provided is the use of a synergistic amount of: 1) glyburide; and 2) milrinone for the manufacture of a medicament for treating insulin resistance.

[0011] Also provided is the use of a synergistic amount of: 1) glyburide; and 2) milrinone for the manufacture of a medicament for treating Syndrome X.

[0012] Also provided is the use of a synergistic amount of: 1) glyburide; and 2) milrinone for the manufacture of a medicament for treating diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, or cataracts.

[0013] Also provided is the use of a synergistic amount of: 1) glyburide; and 2) milrinone for the manufacture of a medicament for treating hyperglycemia

[0014] Also provided is the use of a synergistic amount of: 1) glyburide; and 2) milrinone for the manufacture of a medicament for treating impaired glucose tolerance.
Also provided are pharmaceutical compositions comprising synergistic amounts of glyburide, and milrinone.

Also provided are kits for the treatment of non-insulin dependent diabetes mellitus, the kits comprising:

a) a first pharmaceutical composition comprising: synergistic amounts of 1) glyburide; and 2) milrinone; further
b) a second pharmaceutical composition comprising a further compound useful for the treatment of non-insulin dependent diabetes mellitus; and

c) a container for the first and second compositions.

In a preferred embodiment of the kits, the further compound is selected from:

- insulin and insulin analogs;
- GLP-1 (7-37) (insulinotropin) and GLP-1 (7-36)-NH₂;
- biguanides;
- glycogen phosphorylase inhibitors;
- aldose reductase inhibitors;
- α₂-antagonists;
- imidazolines;
- glitazones (thiazolidinediones);
- PPAR-gamma agonists;
- fatty acid oxidation inhibitors;
- α-glucosidase inhibitors;
- β-agonists;
- lipid-lowering agents;
- antiobesity agents;
- vanadate, vanadium complexes and peroxovanadium complexes;
- amylin antagonists;
- glucagon antagonists;
- gluconeogenesis inhibitors;
- somatostatin agonists and antagonists; or
- antilipolytic agents.

In a more preferred embodiment of the kits, the further compound is selected from LysPro insulin, GLP-1 (7-37) (insulinotropin), GLP-1 (7-36)-NH₂, metformin, phenformin, buformin, midaglizole, isaglizole, deriglizole, ida-zoxan, efaroxan, fluparoxan, linogliride, cigitazone, pioglitazone, englitazone, troglitazone, rosiglitazone, clomoxir, etomoxir, acarbose, miglitol, emiglitate, voglibose, MDL-25,637, camiglibose, MDL-73,945, BRL 35135, BRL 37344, Ro 16-8714, ICI D7114, CL 316,243, benfluorex, fenfluramine, Naglivan®, acipimox, WAG 994, Symlin™, or AC2993.

In another preferred embodiment of the kits, the further compound is selected from insulin, biguanides, or thiazolidinediones.

Also provided are kits for the treatment of non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance, the kits comprising:

a) a first pharmaceutical composition comprising: synergistic amounts of 1) glyburide; and 2) milrinone;

b) a second pharmaceutical composition comprising a further compound useful for the treatment of non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance; and

c) a container for the first and second compositions.

Figure 1 is an isobologram that shows the synergistic effect of combinations of milrinone and glyburide on insulin secretion.
Detailed Description of the Invention

[0022] The present invention provides use of a synergistic amount of: 1) glyburide; and 2) milrinone for the manufacture of a medicament for treating non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance.

[0023] The present invention also provides kits and pharmaceutical compositions that comprise: synergistic amounts of 1) glyburide; and 2) milrinone.

[0024] In addition, the present invention provides kits and pharmaceutical compositions that comprise: synergistic amounts of 1) glyburide; 2) milrinone; and 3) an additional compound useful for the treatment of non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance.

[0025] Certain terms and phrases that are used in this application are defined below.

[0026] The phrase "synergistic amount" means that the therapeutic effect of glyburide, when administered in combination with milrinone, is greater than the predicted additive therapeutic effect of glyburide and milrinone when administered alone.

[0027] The phrase "therapeutic effect" means an amount of a compound or combination of compounds that treats a disease; ameliorates, attenuates, or eliminates one or more symptom of a particular disease; or prevents or delays the onset of one or more symptom of a particular disease.

[0028] The term "patient" means animals, such as dogs, cats, cows, horses, sheep, and humans. Particularly preferred patients are mammals. The term patient includes males and females.

[0029] The phrase "pharmaceutically acceptable" means that the carrier, diluent, vehicle, excipients, and/or salt must be compatible with the other ingredients of the formulation, and not deleterious to the patient.

[0030] The terms "glyburide" and "milrinone" and grammatical variations thereof, includes the stereoisomers of these compounds, pharmaceutically acceptable salts of the compounds, prodrugs of the compounds, and pharmaceutically acceptable salts of the prodrugs.

[0031] The terms "treatment", "treat" or "treatment" include preventative (e.g., prophylactic) and palliative treatment.

[0032] Patients at risk for having non-insulin dependent diabetes mellitus include obese patients, patients having polycystic ovary syndrome, impaired glucose tolerance, insulin resistance, or having or having had gestational diabetes.

[0033] The glyburide and milrinone of the present invention are administered to a patient in synergistic amounts. It has been surprisingly and unexpectedly discovered that administration of a combination of: 1) glyburide; and 2) milrinone results in greater therapeutic effect than the effect expected from the additive effects of each of the compounds.

[0034] The compounds can be administered alone or as part of a pharmaceutically acceptable composition or formulation. In addition, the glyburide and milrinone can be administered all at once, as for example, by a bolus injection, multiple times, such as by a series of tablets, or delivered substantially uniformly over a period of time, as for example, using transdermal delivery. It is also noted that the dose of the glyburide and milrinone can be varied over time.

[0035] In addition, the glyburide and milrinone of the present invention can be administered alone, or in combination with other pharmaceutically active compounds. The other pharmaceutically active compounds can be intended to treat the same diseases as the glyburide or milrinone or different diseases. If the patient is to receive or is receiving multiple compounds, the compounds can be administered simultaneously, or sequentially in any order. For example, in the case of tablets, the active compound(s) can be found in one tablet or in separate tablets, which can be administered at once or sequentially in any order. In addition, it should be recognized that the compositions can be different forms. For example, one or more compounds may be delivered via a tablet, while another is administered via injection or orally as a syrup. All combinations, delivery methods and administration sequences are contemplated.

[0036] Since the present invention contemplates the treatment of diseases with a combination of pharmaceutically active agents that can be administered separately, the invention further relates to combining separate pharmaceutical compositions in kit form. In one embodiment, a kit comprises two separate pharmaceutical compositions: one composition comprising glyburide and milrinone; and the second composition comprising a second pharmaceutically active compound. In another embodiment, a kit comprises two separate pharmaceutical compositions: one composition comprising glyburide; and the second composition comprising milrinone. In still another embodiment, the kit comprises three separate pharmaceutical compositions: one composition comprising glyburide; the second composition comprising milrinone; and the third composition comprising a third pharmaceutically active compound. Other kit variations for the glyburide and milrinone are possible, and these variations are intended to be encompassed by the present invention. The kits also comprise a container for the separate compositions such as a divided bottle or a divided foil packet. Additional examples of containers include syringes, boxes, bags, and the like. Typically, the kits comprise directions for the administration of the separate components. The kit form is particularly advantageous when the separate components are preferably administered in different dosage forms (e.g., oral and parenteral), are administered at different dosage intervals, or when titration of the individual components of a combination of compounds is desired by the
prescribing physician.

[0037] An example of such a kit is a blister pack. Blister packs are well known in the packaging industry and are being widely used for the packaging of pharmaceutical unit dosage forms (tablets, capsules, and the like). Blister packs generally consist of a sheet of relatively stiff material covered with a foil of a preferably transparent plastic material. During the packaging process recesses are formed in the plastic foil. The recesses have the size and shape of the tablets or capsules to be packed. Next, the tablets or capsules are placed in the recesses and the sheet of relatively stiff material is sealed against the plastic foil at the face of the foil that is opposite from the direction in which the recesses were formed. As a result, the tablets or capsules are sealed in the recesses between the plastic foil and the sheet. Preferably, the strength of the sheet is such that the tablets or capsules can be removed from the blister pack by manually applying pressure on the recesses whereby an opening is formed in the sheet at the place of the recess. The tablet or capsule can then be removed via said opening.

[0038] It may be desirable to provide a memory aid on the kit, e.g., in the form of numbers next to the tablets or capsules whereby the numbers correspond with the days of the regimen which the tablets or capsules so specified should be ingested. Another example of such a memory aid is a calendar printed on the card, e.g., as follows "First Week, Monday, Tuesday, ... etc.... Second Week, Monday, Tuesday," etc. Other variations of memory aids will be readily apparent. A “daily dose” can be a single tablet or capsule or several pills or capsules to be taken on a given day. Also, a daily dose of a compound of the present invention can consist of one tablet or capsule, while a daily dose of a second compound can consist of several tablets or capsules and vice versa. The memory aid should reflect this and assist in correct administration of the compounds.

[0039] In another embodiment of the invention, a dispenser designed to dispense the daily doses one at a time in the order of their intended use is provided. Preferably, the dispenser is equipped with a memory aid, so as to further facilitate compliance with the dosing regimen. An example of such a memory aid is a mechanical counter that indicates the number of daily doses that have been dispensed. Another example of such a memory aid is a battery-powered micro-chip memory coupled with a liquid crystal readout, or audible reminder signal which, for example, reads out the date that the last daily dose has been taken and/or reminds a patient when the next dose is to be taken.

[0040] The glyburide and milrinone of the present invention and other pharmaceutically active compounds, if desired, can be administered to a patient either orally, rectally, parenterally, (for example, intravenously, intramuscularly, or subcutaneously) intracisternally, intravaginally, intraperitoneally, intravascularly, locally (for example, powders, ointments or drops), or as a buccal or nasal spray. It is also noted that the administration methods include the use of controlled release compositions, including sustained release and delayed release, and immediate release compositions and combinations thereof.

[0041] Compositions suitable for parenteral injection may comprise physiologically acceptable sterile aqueous or nonaqueous solutions, dispersions, suspensions, emulsions, or sterile powders for reconstitution into sterile injectable solutions or dispersions. Examples of suitable aqueous and nonaqueous carriers, diluents, solvents, or vehicles include water, ethanol, poloxyls (propylene glycol, polyethylene glycol, glycerol, and the like), suitable mixtures thereof, vegetable oils (such as olive oil) and injectable organic esters such as ethyl oleate. Proper fluidity can be maintained, for example, by the use of a coating such as lecithin, by the maintenance of the required particle size in the case of dispersions, or by the use of surfactants.

[0042] These compositions may also contain adjuvants such as preserving, wetting, emulsifying, and dispersing agents. Microorganism contamination can be prevented by adding various antibacterial and antifungal agents to the compositions, for example, parabens, chlorobutanol, phenol, sorbic acid, and the like. It may also be desirable to include isotonic agents, for example, sugars, sodium chloride, and the like. Prolonged absorption of injectable pharmaceutical compositions can be brought about by the use of agents delaying absorption, for example, aluminum monostearate or gelatin.

[0043] Solid dosage forms for oral administration include capsules, tablets, powders, and granules. In such solid dosage forms, the compound is admixed with at least one inert customary excipient (or carrier) such as sodium citrate or dicalcium phosphate or (a) fillers or extenders, as for example, starches, lactose, sucrose, mannitol, or silicic acid; (b) binders, as for example, carboxymethylcellulose, alginates, gelatin, polyvinylpyrrolidone, sucrose, or acacia; (c) humectants, as for example, glycerol; (d) disintegrating agents, as for example, agar-agar, calcium carbonate, potato or tapioca starch, alginic acid, certain complex silicates, or sodium carbonate; (e) solution retarders, as for example, paraffin; (f) absorption accelerators, as for example, quaternary ammonium compounds; (g) wetting agents, as for example, cetyl alcohol and glycerol monostearate; (h) adsorbents, as for example, kaolin or bentonite; and (i) lubricants, as for example, talc, calcium stearate, magnesium stearate, solid polyethylene glycols, sodium lauryl sulfate, or mixtures thereof. In the case of capsules, and tablets, the dosage forms may also comprise buffering agents.

[0044] Solid compositions of a similar type may also be used as fillers in soft and hard filled gelatin capsules using such excipients as lactose or milk sugar, as well as high molecular weight polyethylene glycols, and the like.

[0045] Solid dosage forms such as tablets, dragees, capsules, pills, and granules can be prepared with coatings and shells, such as enteric coatings and others well known in the art. They may also contain opacifying agents, and can
also be of such composition that they release the compound or compounds in a certain part of the intestinal tract in a delayed manner. Examples of embedding compositions that can be used are polymeric substances and waxes. The compounds can also be in micro-encapsulated form, if appropriate, with one or more of the above-mentioned excipients.

**[0046]** Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, and elixirs. In addition to the active compounds, the liquid dosage form may contain inert diluents commonly used in the art, such as water or other solvents, solubilizing agents and/or emulsifiers, as for example, ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propylene glycol, 1,3-butylene glycol, dimethylformamide, oils, in particular, cottonseed oil, groundnut oil, corn germ oil, olive oil, castor oil, or sesame seed oil, glycerol, tetrahydrofurfuryl alcohol, polyethylene glycols or fatty acid esters of sorbitan, or mixtures of these substances, and the like.

**[0047]** Besides such inert diluents, the composition can also include adjuvants, such as wetting agents, emulsifying and/or suspending agents, sweetening, flavoring, or perfuming agents.

**[0048]** Suspensions, in addition to the compound, may contain suspending agents, as for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol or sorbitan esters, microcrystalline cellulose, aluminum metaphosphate, bentonite, agar-agar, or tragacanth, or mixtures of these substances, and the like.

**[0049]** Compositions for rectal or vaginal administration can be prepared by mixing the compounds of the present invention with suitable non-irritating excipients or carriers such as cocoa butter, polyethylene glycol or a suppository wax, which are solid at ordinary room temperature, but liquid at body temperature, and therefore, melt in the rectum or vaginal cavity and release the active component.

**[0050]** Dosage forms for topical administration include ointments, powders, sprays and inhalants. The compound or compounds are admixed under sterile conditions with a physiologically acceptable carrier, and any preservatives, buffers, or propellants that may be required. Ophthalmic formulations, eye ointments, powders, and solutions are also contemplated as being within the scope of this invention.

**[0051]** Each of the glyburide and milrinone of the present invention can be administered to a patient at synergistic dosage levels in the range of 0.1 to 7,000 mg per day. A preferred dosage range is 0.1 to 500 mg per day. The specific dosage and dosage range that can be used for each compound depends on a number of factors, including the requirements of the patient, the severity of the condition or disease being treated, and the pharmacological activity of the compound or compounds being administered. The determination of dosage ranges and optimal dosages for a particular patient is well within the ordinary skill in the art in view of the present disclosure.

**[0052]** Suitable synergistic dosage ranges can be correlated with desired plasma concentrations. For example, an effective plasma concentration of milrinone is 10ng/mL to 10 mg/mL. A preferred plasma concentration is 100ng/mL to 1 mcg/mL. Similarly, an effective plasma concentration for glyburide is 5 ng/mL to 100 mcg/mL. A preferred plasma concentration is 49 ng/mL to 5 mcg/mL.

**[0053]** The following paragraphs describe exemplary formulations, dosages, etc., useful for non-human patients. The administration of glyburide and milrinone in the present invention can be effected orally or non-orally, for example by injection. An amount of a compound or combination of compounds is administered such that a synergistic dose is received, generally a daily dose which, when administered orally to an animal is usually between 0.01 and 100 mg/kg of body weight, preferably between 0.1 and 50 mg/kg of body weight of each of: glyburide and milrinone. It is noted that each of the compounds administered in a combination can have the same or a different dosage. Conveniently, the medication can be carried in the drinking water so that a therapeutic dosage of the combination of compounds is ingested with the daily water supply. The combination of compounds can be directly metered into drinking water, preferably in the form of a liquid, water-soluble concentrate (such as an aqueous solution of a water soluble salt). Conveniently, the compounds of the present invention can also be added directly to the feed, as such, or in the form of an animal feed supplement, also referred to as a premix or concentrate. A premix or concentrate in a carrier is more commonly employed for the inclusion of a compound or compounds in the feed. Suitable carriers are liquid or solid, as desired, such as water, various meals such as alfalfa meal, soybean meal, cottonseed oil meal, linseed oil meal, corn cob meal and corn meal, molasses, urea, bone meal, and mineral mixes such as are commonly employed in poultry feeds. A particularly effective carrier is the respective animal feed itself; that is, a small portion of such feed. The carrier facilitates uniform distribution of the compound or combination of compounds in the finished feed with which the premix is blended. It is important that a compound or combination of compounds be thoroughly blended into the premix and, subsequently, the feed. In this respect, the compound or combination of compounds may be dispersed or dissolved in a suitable oily vehicle such as soybean oil, corn oil, cottonseed oil, and the like, or in a volatile organic solvent and then blended with the carrier. It will be appreciated that the proportions of the compound or combination of compounds in the concentrate are capable of wide variation since the amount of a compound or combination of compounds in the finished feed may be adjusted by blending the appropriate proportion of premix with the feed to obtain the desired level of the compound or compounds.

**[0054]** High potency concentrates may be blended by the feed manufacturer with proteinaceous carrier such as soybean oil meal or other meals, as described above, to produce concentrated supplements which are suitable for
direct feeding to animals. In such instances, the animals are permitted to consume the usual diet. Alternatively, such concentrated supplements may be added directly to the feed to produce a nutritionally balanced, finished feed containing a synergistic amount of the compounds according to the present invention. The mixtures are thoroughly blended by standard procedures, such as in a twin shell blender, to ensure homogeneity.

If the supplement is used as a top dressing for the feed, it likewise helps to ensure uniformity of distribution of the compound or combination of compounds across the top of the dressed feed.

For parenteral administration in non-human animals, glyburide and milrinone may be prepared in the form of a paste or a pellet and administered as an implant, usually under the skin of the head or ear of the animal.

In general, parenteral administration involves the injection of a sufficient amount of glyburide, in combination with milrinone to provide the animal with 0.01 to 100 mg/kg/day of body weight of each of the active ingredients in the combination.

Paste formulations can be prepared by dispersing the compounds in a pharmaceutically acceptable oil such as peanut oil, sesame oil, corn oil or the like.

Pellets containing an effective amount of compounds of the present invention can be prepared by admixing compounds of the present invention with a diluent such as carbowax, camauba wax, or the like, and a lubricant, such as magnesium or calcium stearate, can be added to improve the pelleting process.

It is, of course, recognized that more than one pellet may be administered to an animal to achieve the desired dose level. Moreover, it has been found that implants may also be made periodically during the animal treatment period in order to maintain the proper level of compound(s) in the animal's body.

The term pharmaceutically acceptable salts or prodrugs includes the carboxylate salts, amino acid addition salts, and prodrugs of glyburide and milrinone that are, within the scope of sound medical judgment, suitable for use with patients without undue toxicity, irritation, allergic response, and the like, commensurate with a reasonable benefit/risk ratio, and effective for their intended use, as well as the zwitterionic forms, where possible.

The term "salts" refers to inorganic and organic salts of glyburide and milrinone. The salts can be prepared in situ during the final isolation and purification, or by separately reacting a purified compound in its free base form with a suitable organic or inorganic acid and isolating the salt thus formed. Representative salts include the hydrobromide, hydrochloride, sulfate, bisulfate, nitrate, acetate, oxalate, palmitate, stearate, laurate, borate, benzoate, lactate, phosphate, tosylate, citrate, maleate, fumarate, succinate, threitol, naphthylate, mesylate, glucoheptonate, lactobionate, and laurylsulphonate salts, or the like. The salts may include cations based on the alkalai and alkaline earth metals, such as sodium, lithium, potassium, calcium, magnesium, and the like, as well as non-toxic ammonium, quaternary ammonium, and amine cations including, but not limited to, ammonium, tetramethylammonium, tetraethylammonium, methylamine, dimethylamine, trimethylamine, diethylamine, ethylamine, and the like. See, for example, S.M. Berge, "Pharmaceutical Salts," J Pharm Sci, 66: 1-19 (1977).

Examples of pharmaceutically acceptable, non-toxic esters of the glyburide and milrinone, if applicable, include C1-C8 alkyl esters. Acceptable esters also include C6-C10cycloalkyl esters, as well as aryalkyl esters such as benzyl. C1-C4 Alkyl esters are preferred. Esters of glyburide or milrinone may be prepared according to methods that are well known in the art.

Examples of pharmaceutically acceptable non-toxic amides of glyburide and milrinone include amides derived from ammonia, primary C1-C8 alkyl amines, and secondary C1-C3 dialkyl amines. In the case of secondary amines, the amine may also be in the form of a 5 or 6 membered heterocycloalkyl group containing at least one nitrogen atom. Amides derived from ammonia, C1-C4 primary alkyl amines, and C1-C3 dialkyl secondary amines are preferred. Amides of glyburide and milrinone may be prepared according to methods well known to those skilled in the art.

The glyburide and/or milrinone of the present invention may contain asymmetric or chiral centers, and therefore, exist in different stereoisomeric forms. It is contemplated that all stereoisomeric forms of the compounds as well as mixtures thereof, including racemic mixtures, form part of the present invention. In addition, the present invention contemplates all geometric and positional isomers. For example, if a compound contains a double bond, both the cis and trans forms, as well as mixtures, are contemplated.

Diastereomeric mixtures can be separated into their individual stereochemical components on the basis of their physical chemical differences by methods known per se, for example, by chromatography and/or fractional crystallization. Enantiomers can be separated by converting the enantiomeric mixture into a diastereomeric mixture by reaction with an appropriate optically active compound (e.g., alcohol), separating the diastereomers and converting (e.g., hydrolyzing) the individual diastereomers to the corresponding pure enantiomers. Also, some of the compounds of this invention may be atropisomers (e.g., substituted biaryls) and are considered as part of this invention.

The glyburide and/or milrinone of the present invention may exist in unsolvated as well as solvated forms with pharmaceutically acceptable solvents such as water, ethanol, and the like. The present invention contemplates and encompasses both the solvated and unsolvated forms.

It is also possible that the glyburide and/or milrinone of the present invention may exist in different tautomeric forms. All tautomers of compounds of the present invention are contemplated.
It is generally accepted that thyroid hormones, specifically, biologically active iodothyronines, are critical to normal development and to maintaining metabolic homeostasis. Thyroid hormones stimulate the metabolism of cholesterol and triglycerides, and they inhibit the uptake of glucose by muscle and adipose tissue. They also increase the metabolic rate of carbohydrates and fats, and they stimulate the growth of bone and muscle. Thyroid hormones are also known to have a number of other effects on the body, including the stimulation of the heart, the improvement of mental function, and the protection of the thyroid gland from damage by radiation.

In addition to the categories and compounds mentioned above, the glucocorticoids and thyroid hormones can also be used to treat a variety of other conditions, including hyperthyroidism, hypothyroidism, and the complications of diabetes mellitus. These conditions are characterized by abnormal levels of thyroid hormones in the bloodstream, and they can result in a range of symptoms, including weight loss, fatigue, and mood changes.

The use of glucocorticoids and thyroid hormones to treat these conditions is based on their ability to regulate the metabolism of other hormones, particularly insulin and glucagon. These hormones are involved in the regulation of blood glucose levels, and they play a critical role in the maintenance of metabolic homeostasis. The use of glucocorticoids and thyroid hormones to treat these conditions is based on their ability to regulate the metabolism of other hormones, particularly insulin and glucagon. These hormones are involved in the regulation of blood glucose levels, and they play a critical role in the maintenance of metabolic homeostasis.
listerol to bile acids and enhance the lipolytic responses of fat cells to other hormones. U.S. Patent Numbers 4,766,121; 4,826,876; 4,910,305; and 5,061,798 disclose certain thyroid hormone mimetics (thyromimetics), namely, 3,5-dibromo-3′-[6-oxo-3(1H)-pyridazinylmethyl]-thyonines. U.S. Patent Number 5,284,971 discloses certain thyromimetic cholesterol lowering agents, namely, 4-(3-cyclohexyl-4-hydroxy or -methoxy phenylsulfonyl)-3,5 dibromo-phenylacetic compounds. U.S. Patent Numbers 5,401,772; 5,654,468; and 5,569,674 disclose certain thyromimetics that are lipid lowering agents, namely, heteroacetic acid derivatives. In addition, certain oxamic acid derivatives of thyroid hormones are known in the art. For example, N. Yokoyama, et al. in an article published in the Journal of Medicinal Chemistry, 38 (4): 695-707 (1995) describe replacing a -CH₂ group in a naturally occurring metabolite of T₃ with an -NH group resulting in -HNCOCO₂H. Likewise, R.E. Steele et al. in an article published in International Congressional Service (Atherosclerosis X) 1066: 321-324 (1995) and Z.F. Stephan et al. in an article published in Atherosclerosis, 126: 53-63 (1996), describe certain oxamic acid derivatives useful as lipid-lowering thyromimetic agents, yet devoid of undesirable cardiac activities.

Each of the thyromimetic compounds referenced above and other thyromimetic compounds can be used in combination with the glyburide and milrinone of the present invention to treat diabetes, insulin resistance, Syndrome X diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts hyperglycemia, hypercholesterolemia, hypertension, hyperlipidemia, atherosclerosis, tissue ischemia or impaired glucose tolerance.

The glyburide and milrinone of the present invention can also be used in combination with aldose reductase inhibitors. Aldose reductase inhibitors constitute a class of compounds that have become widely known for their utility in preventing and treating conditions arising from complications of diabetes, such as diabetic neuropathy and nephropathy. Such compounds are well known to those skilled in the art and are readily identified by standard biological tests. For example, the aldose reductase inhibitors zopolrestat, 1-phthalazineacetic acid, 3,4-dihydro-4-oxo-3-[[5-(trifluoromethyl)-2-benzothiazolyl]methyl]-, and related compounds are described in U.S. Patent 4,939,140.

Aldose reductase inhibitors have been taught for use in lowering lipid levels in mammals. See, for example, U. S. Patent 4,492,706 and EP 0 310 931 A2.

U. S. Patent 5,064,830 discloses the use of certain oxophthalazinyl acetic acid aldose reductase inhibitors, including zopolrestat, for lowering of blood uric acid levels.

Commonly assigned U.S. Patent 5,391,551 discloses the use of certain aldose reductase inhibitors, including zopolrestat, for lowering blood lipid levels in humans. The disclosure teaches that therapeutic utilities derive from the treatment of diseases caused by an increased level of triglycerides in the blood, such diseases include cardiovascular disorders such as thrombosis, arteriosclerosis, myocardial infarction, and angina pectoris. A preferred aldose reductase inhibitor is zopolrestat.

The term aldose reductase inhibitor refers to compounds that inhibit the biorconversion of glucose to sorbitol, which is catalyzed by the enzyme aldose reductase.

Any aldose reductase inhibitor may be used in a combination with the glyburide and milrinone of the present invention. Aldose reductase inhibition is readily determined by those skilled in the art according to standard assays (J. Malone, Diabetes, 29:861-864 (1980), "Red Cell Sorbitol, an Indicator of Diabetic Control"). A variety of aldose reductase inhibitors are described herein; however, other aldose reductase inhibitors useful in the compositions and methods of this invention will be known to those skilled in the art.

The activity of an aldose reductase inhibitor in a tissue can be determined by testing the amount of aldose reductase inhibitor that is required to lower tissue sorbitol (i.e., by inhibiting the further production of sorbitol consequent to blocking aldose reductase) or lower tissue fructose (by inhibiting the production of sorbitol consequent to blocking aldose reductase and consequently the production of fructose).

Accordingly, examples of aldose reductase inhibitors useful in the present invention include:

1. 3-(4-bromo-2-fluorobenzyl)-3,4-dihydro-4-oxo-1-phthalazineacetic acid (ponalrestat, US 4,251,528);
2. N[[5-(trifluoromethyl)-6-methoxy-1-naphthalenyl][thioxomethyl]-N-methylglycine (tolrestat, US 4,600,724);
3. 5-[(Z,E)-β-methylinnaylidene]-4-oxo-2-thioxo-3-thiazolideneacetic acid (epalrestat, US 4,464,382, US 4,791,126, US 4,831,045);
4. 3-(4-bromo-2-fluorobenzyl)-7-chloro-3,4-dihydro-2,4-dioxo-1(2H)-quinazolineacetic acid (zenarestat, US 4,734,419, and 4,883,800);
5. 2R,4R-6,7-dichloro-4-hydroxy-2-methylchroman-4-acetic acid (US 4,791,126, US 4,831,045);
6. 2R,4R-6,7-dichloro-6-fluoro-4-hydroxy-2-methylchroman-4-acetic acid (US 4,883,410);
7. 3,4-dihydro-2,8-diosopropy-3-oxo-2H-1,4-benzoxazine-4-acetic acid (US 4,771,050);
8. 3,4-dihydro-3-oxo-4-[[4,5,7-trifluoro-2-benzothiazolyl)methyl]-2H-1,4-benzothiazine-2-acetic acid (SPR-210, U. S. 5,252,572);
polycystic ovary syndrome, cataracts, hyperglycemia, hypercholesterolemia, hypertension, hyperlipidemia, atherosclerosis, tissue ischemia, or impaired glucose tolerance.

Each of the glucocorticoid receptor antagonists referenced above and other glucocorticoid receptor antagonists can be used in combination with a compound of the present invention, including dexamethasone, prednisone, prednisilone. By definition, glucocorticoid receptor antagonists bind to the receptor and prevent glucocorticoid receptor agonists from binding and eliciting GR mediated events, including transcription. RU486 is an example of a non-selective glucocorticoid receptor antagonist. GR antagonists can be used in combination with the glyburide and milrinone of the present invention to treat diabetes, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, hypercholesterolemia, hypertension, hyperlipidemia, atherosclerosis, tissue ischemia, or impaired glucose tolerance.

The glyburide and milrinone of the present invention can also be used in combination with glucocorticoid receptor antagonists. The glucocorticoid receptor (GR) is present in glucocorticoid responsive cells where it resides in the cytosol in an inactive state until it is stimulated by an agonist. Upon stimulation the glucocorticoid receptor translocates to the cell nucleus where it specifically interacts with DNA and/or protein(s) and regulates transcription in a glucocorticoid responsive manner. Two examples of proteins that interact with the glucocorticoid receptor are the transcription factors, API and NFκB. Such interactions result in inhibition of API- and NFκB-mediated transcription and are believed to be responsible for the antiinflammatory activity of endogenously administered glucocorticoids. In addition, glucocorticoids may also exert physiologic effects independent of nuclear transcription. Biologically relevant glucocorticoid receptor agonists include cortisol and corticosterone. Many synthetic glucocorticoid receptor agonists exist including dexamethasone, prednisone and prednisilone. By definition, glucocorticoid receptor antagonists bind to the receptor and prevent glucocorticoid receptor agonists from binding and eliciting GR mediated events, including transcription. RU486 is an example of a non-selective glucocorticoid receptor antagonist. GR antagonists can be used in the treatment of diseases associated with an excess or a deficiency of glucocorticoids in the body. As such, they may be used to treat the following: obesity, diabetes, cardiovascular disease, hypertension, Syndrome X, depression, anxiety, glaucoma, human immunodeficiency virus (HIV) or acquired immunodeficiency syndrome (AIDS), neurodegeneration (for example, Alzheimer’s and Parkinson’s), cognition enhancement, Cushing’s Syndrome, Addison’s Disease, osteoporosis, frailty, inflammatory diseases (such as osteoarthritis, rheumatoid arthritis, asthma and rhinitis), adrenal function, viral infection, immunodeficiency, immunomodulation, autoimmune diseases, allergies, wound healing, compulsive behavior, multi-drug resistance, addiction, psychosis, anorexia, cachexia, post-traumatic stress syndrome, post-surgical bone fracture, medical catabolism and prevention of muscle frailty. Examples or GR antagonists that can be used in combination with a compound of the present invention include the compounds disclosed in U.S. patent application number 60/132,130.

Procedures for making the aldose reductase inhibitors 20-29 can be found in PCT publication number WO 99/26659.

Each of the aldose reductase inhibitors referenced above and other aldose reductase inhibitors can be used in combination with the glyburide and milrinone of the present invention to treat diabetes, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic cardiomyopathy, post-surgical bone fracture, medical catabolism and prevention of muscle frailty. Examples or GR antagonists that can be used in combination with the glyburide and milrinone of the present invention include the compounds disclosed in U.S. patent application number 60/132,130.
genase inhibitors. Sorbitol dehydrogenase inhibitors lower fructose levels and have been used to treat or prevent diabetic complications such as neuropathy, retinopathy, nephropathy, cardiomyopathy, microangiopathy, and macroangiopathy. U.S. patent numbers 5,728,704 and 5,866,578 disclose compounds and a method for treating or preventing diabetic complications by inhibiting the enzyme sorbitol dehydrogenase.

[0092] Each of the sorbitol dehydrogenase inhibitors referenced above and other sorbitol dehydrogenase inhibitors can be used in combination with the glyburide and milrinone of the present invention to treat diabetes, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, hypercholesterolemia, hypertension, hyperlipidemia, atherosclerosis, tissue ischemia, or impaired glucose tolerance.

[0093] The glyburide and milrinone of the present invention can also be used in combination with sodium-hydrogen exchanger type 1 (NHE-1) inhibitors. NHE-1 inhibitors can be used to reduce tissue damage resulting from ischemia. Of great concern is tissue damage that occurs as a result of ischemia in cardiac, brain, liver, kidney, lung, gut, skeletal muscle, spleen, pancreas, nerve, spinal cord, retina tissue, the vasculature, or intestinal tissue. NHE-1 inhibitors can also be administered to prevent perioperative myocardial ischemic injury. Examples of NHE-1 inhibitors include those disclosed in PCT patent application number PCT/IB99/00206.

[0094] Each of the NHE-1 inhibitors referenced above and other NHE-1 inhibitors can be used in combination with the glyburide and milrinone of the present invention to treat diabetes, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, hypercholesterolemia, hypertension, hyperlipidemia, atherosclerosis, tissue ischemia, or impaired glucose tolerance.

Examples

Measurement of Insulin Secretion from INS-1 Cells

[0095] The INS-1 cell is a β-cell line derived from an X-ray induced transplantable rat insulinoma. Asfari, M. et al., Endocrinology, 130:167-178 (1992). When maintained in cell culture, the cells of this line secrete insulin in response to the same stimuli that stimulate insulin secretion from the β-cells present in the intact islet of Langerhans. The cells are grown until confluent in 24-well tissue culture plates in a standard tissue culture medium [RPMI1640 without L-glutamine (Gibco, Rockville, MD) containing: 10% fetal bovine serum (Gibco), 1% penicillin/streptomycin (Gibco), 1% L-glutamine (Gibco), 10 mM sodium HEPES buffer (Gibco) pH 7.4, 1 mM sodium pyruvate (Sigma, St. Louis) and 50µM 2-mercaptoethanol (Sigma).

[0096] Secretion of insulin from these cells was measured as follows. The incubation medium was removed from the confluent cell monolayers by aspiration and replaced with Kreb’s-Ringer bicarbonate (KRB) buffer without glucose, but containing 0.1 % bovine serum albumin (BSA). The cells were incubated for 2 hours in this medium in a humidified 37°C incubator filled with air with 5% CO2 by volume added. The pre-incubation medium was then removed by aspiration and replaced with KRB buffer (pH 7.4) containing 0.1% BSA, and glucose and stimulatory compounds at the desired concentrations. The plates were returned to the incubator for four hours. At the end of this time, aliquots of the buffer were collected from each well and the insulin concentration present was measured by radioimmunoassay (Linco Research, Inc., St. Louis, MO).

Measurement of Insulin Secretion from Rat Islets

[0097] Rat islets of Langerhans were prepared from the pancreata of normal Sprague-Dawley rats by an adaptation of a published method. Lacy, P.E. et al., Diabetes, 16:35-39 (1967). This method is described below.

[0098] Rats were anaesthetized by intraperitoneal administration of 35-50 mg/kg of pentobarbital. The abdominal cavity was opened and approximately 15ml of a buffered solution of collagenase introduced into the pancreatic duct via a needle. The solution comprised 3mg/ml collagenase in magnesium-free Hanks buffer (127 mM NaCl, 20 mM HEPES, 5.4 mM KCl, 0.34 mM Na2HPO4, 1 mM KH2PO4, 1.19 mM CaCl2, pH 7.4). The pancreas was then dissected free of connective tissue, excised from the body and minced with scissors in a beaker containing additional collagenase buffer as described above. The pancreatic tissue was then further digested by incubating it with stirring at 37°C in the collagenase buffer for 10-15 minutes. The tissue was then transferred to two 16 x 125 mm tubes and centrifuged very briefly to settle the solid material. Half of each supernatant was removed and replaced with magnesium-free Hanks buffer without collagenase. The tubes were shaken vigorously by hand and then centrifuged as before. The wash, shake and centrifuge procedure was then repeated twice. The pancreatic digest was then washed 4 more times with magnesium-free Hanks buffer, pouring off all of the supernatant after each centrifugation step and omitting the shaking. After the final wash, the pellets were mixed with 4 ml of a 27% (w/v) solution of Ficoll (Sigma, St. Louis, MO) in magnesium-free Hanks buffer and transferred to 30 ml tubes. A 4 ml volume of 23% (w/v) Ficoll in magnesium-free Hanks
buffer was layered on top followed by 4 ml of 20.5% Ficoll in magnesium-free Hanks buffer and 4 ml of 11% Ficoll in magnesium-free Hanks buffer. The tubes were centrifuged for 10 minutes at 250 x g. Islets were collected from the 11%/20.5% and 20.5%/23% interfaces and placed in 50 ml tubes. They were washed twice with Hanks buffer containing magnesium (127 mM NaCl, 20 mM HEPES, 5.4 mM KCl, 0.34 mM Na3HPO4, 1 mM KH2PO4, 0.81 mM MgSO4, 1.19 mM CaCl2, pH 7.4), sedimenting the islets by centrifugation for 10 minutes at 250 x g between washes. After the last centrifugation step, the pellet was transferred to a petri dish and the islets manually transferred from the dish to an appropriate culture vessel using a 200 µl constricted pipette.

Once the islets were separated from residual non-islet tissue, they were either used immediately or maintained in a standard tissue culture medium [RPMI1640 medium (Gibco) containing 10% fetal bovine serum (Gibco), 1% antibiotic/antimycotic (Gibco) and 22mM glucose].

In Vitro Insulin Secretion Assay and Statistical Analysis

Data from in vitro experiments in the INS-1 cell assay described above combining glyburide and milrinone for induction of insulin secretion were analyzed. A total of 399 data points from six experiments were collected. The response is the amount of insulin secretion at various combinations of different concentrations of glyburide and milrinone. The response data from each experiment was normalized by the concentration of cells of β-cell lines in plates for the experiment. The data from the six experiments were then combined in the statistical analysis.

A response surface was constructed from the combined data. From the response surface, a contour line corresponding to 95% of the maximum response level due to glyburide alone was obtained. This contour line is shown in Figure 1. The contour line represents all the combinations of the two drugs that produce this fixed amount of response based on the data from the experiments. The plot in Figure 1 is called an isobologram. Isobolograms are used in the study of synergism and are well known to those skilled in the art. If only an additive effect exists, the contour line would be a straight line connecting points C and D. Synergism exists if the actual contour is below the straight line.

The magnitude of the synergistic effect is measured by how far the contour line is from the straight line. The line representing a fixed ratio of the two drugs is a straight line that goes through the origin in Figure 1. This line intercepts the contour at point A and the additive straight line at point B. For a given ratio of the two drugs, we assess the magnitude of synergistic effect by a dose reduction factor \( r \) defined as:

\[
r = \frac{\text{Amount of Glyburide at } A}{\text{Amount of Glyburide at } B} = \frac{\text{Amount of Milrinone at } A}{\text{Amount of Milrinone at } B}.
\]

The points C and D represent the equivalent concentrations for glyburide and milrinone, respectively. If we define C and D as one unit for glyburide and milrinone, respectively, then the dose reduction factor \( r \) represents the fraction of the combined drugs needed to achieve the same level of response achieved by one unit of either drug individually. So if \( r \) is smaller than 1, then synergism exists. The smaller the \( r \), the stronger the synergistic effect. It is possible to mathematically determine the ratio that produced the biggest synergistic effect and the dose reduction factor \( r \) associated with the ratio. We found that the ratio is glyburide/milrinone = 2.4, and the corresponding dose reduction factor \( r \) is 0.259. The implication is that with this ratio of the two drugs, only 0.259 of one unit of the combined amount of glyburide and milrinone is needed to produce the same amount of response corresponding to one unit of either glyburide or milrinone alone. Figure 1 shows that for a wide range of ratios synergism exists.

Since the contour line, as well as the dose reduction factor \( r \) is derived from data, they are subject to uncertainties associated with the data. The uncertainties come from factors such as measurement errors, β-cell line variations, and other random factors. When an observed dose reduction factor \( r \) is less than 1, the main objective of the statistical analysis is to determine whether it is real or it is due to random chance. This is accomplished by first calculating the standard error of \( r \), \( sd(r) \), and then calculating the probability of having a dose reduction factor no greater than the observed \( r \) according to a normal distribution with mean 1 and standard deviation \( sd(r) \). This probability is the p-value. If the p-value is less than 0.05, we conclude that the synergistic effect is statistically significant. Table 1 lists the dose reduction factor and the associated p-value for each of the selected ratios of the two drugs. We see that for each of the selected ratios, the synergistic effect is significant.
From the statistical analysis, we conclude that over a wide range of ratios of combinations of the two drugs, the synergistic effect is statistically significant. We also found that the ratio of the two drugs that produced the maximum synergistic effect is glyburide/milrinone = 2.4. With this ratio, only 0.259 of one unit of the combined amount of glyburide and milrinone was needed to produce the same amount of response corresponding to one unit of either glyburide or milrinone alone. It is noted that the absolute concentration of milrinone was in the range of about 1 to about 100 micromolar and in the range of about 0.1 to about 10 micromolar for glyburide. Various concentrations of each drug that corresponded to a particular ratio were tested.

**Claims**

1. The use of a synergistic amount of: 1) glyburide and 2) milrinone, for the manufacture of a medicament for treating or preventing non-insulin dependent diabetes mellitus.

2. The use of a synergistic amount of: 1) glyburide and 2) milrinone, for the manufacture of a medicament for treating or preventing insulin resistance.

3. The use of a synergistic amount of: 1) glyburide and 2) milrinone, for the manufacture of a medicament for treating or preventing syndrome X.

4. The use of a synergistic amount of: 1) glyburide and 2) milrinone, for the manufacture of a medicament for treating or preventing diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, or cataracts.

5. The use of a synergistic amount of: 1) glyburide and 2) milrinone, for the manufacture of a medicament for treating or preventing hyperglycemia.

6. The use of a synergistic amount of: 1) glyburide and 2) milrinone, for the manufacture of a medicament for treating or preventing impaired glucose tolerance.

7. A pharmaceutical composition comprising synergistic amounts of glyburide and milrinone.

8. A kit for the treatment of non-insulin dependent diabetes mellitus, the kit comprising:
a) a first pharmaceutical composition comprising synergistic amounts of 1) glyburide; and 2) milrinone;

b) a second pharmaceutical composition comprising a further compound useful for the treatment of non-insulin dependent diabetes mellitus; and

c) a container for containing the first and second compositions.

9. A kit in accordance with claim 8 wherein the further compound is selected from:

- insulin and insulin analogs;
- GLP-1 (7-37) (insulinotropin) and GLP-1 (7-36)-NH₂;
- biguanides;
- glycogen phosphorylase inhibitors;
- aldose reductase inhibitors;
- α₂-agonists;
- imidazolines;
- glitazones (thiazolidinediones);
- PPAR-gamma agonists;
- fatty acid oxidation inhibitors;
- α-glucosidase inhibitors;
- β-agonists;
- lipid-lowering agents;
- anti-obesity agents;
- vanadate, vanadium complexes and peroxovanadium complexes;
- amylin antagonists;
- glucagon antagonists;
- gluconeogenesis inhibitors;
- somatostatin agonists and antagonists; or
- anti-lipolytic agents.

10. A kit in accordance with claim 8 wherein the further compound is selected from LysPro insulin, GLP-1 (7-37) (insulinotropin), GLP-1 (7-36)-NH₂, metformin, phenformin, buformin, midaglizole, isaglidole, deriglidole, idaqoxan, efaroxan, fluparoxan, linogliride, ciglitazone, pioglitazone, troglitazone, rosiglitazone, clomoxir, etomoxir, acarbose, miglitol, emiglitate, voglibose, MDL-25,637, camiglibose, MDL-73,945, BRL 35135, BRL 37344, Ro 16-8714, ICI D7114, CL 316,243, benfluorex, fenfluramine, Naglivan®, acipimox, WAG 994, Symlin™, or AC2993.

11. A kit in accordance with claim 8 wherein the further compound is selected from insulin, biguanides, or thiazolidinediones.

12. A kit for the treatment of non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance, the kit comprising:

a) a first pharmaceutical composition comprising synergistic amounts of 1) glyburide; and 2) milrinone;

b) a second pharmaceutical composition comprising a further compound useful for the treatment of non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance, and

c) a container for containing the first and second compositions.

13. A kit for the treatment of non-insulin dependent diabetes mellitus, insulin resistance, Syndrome X, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, diabetic cardiomyopathy, polycystic ovary syndrome, cataracts, hyperglycemia, or impaired glucose tolerance, the kit comprising:

a) a first pharmaceutical composition comprising glyburide; the amounts of glyburide and milrinone being synergistic amounts
b) a second pharmaceutical composition comprising milrinone; and

c) a container for containing the first and second compositions.

Patentansprüche

8. Kit zur Behandlung von nicht-insulinabha"ngigem Diabetes mellitus, wobei das Kit

   a) eine erste pharmazeutische Zusammensetzung, die synergistische Mengen von 1) Glyburide und 2) Milrinone umfasst;

   b) eine zweite pharmazeutische Zusammensetzung, die eine weitere zur Behandlung von nicht-insulinabh"ngigem Diabetes mellitus verwendbare Verbindung umfasst; und

   c) einen Behälter zur Aufnahme der ersten und zweiten Zusammensetzungen umfasst.

9. Kit nach Anspruch 8, wobei die weitere Verbindung ausgewählt ist aus:

   Insulin und Insulinanaloga,
   GLP-1(7-37)(Insulinotropin) und GLP-1(7-36)-NH2,
   Biguaniden,
   Glykogenphosphorylaseinhibitoren,
   Aldoseductaseinhibitoren,
   α2-Antagonisten,
   Imidazolinen,
   Glitazonen (Thiazolidindionen),
   PPAR-gamma-Agonisten,
   Fettsäureoxidationsinhibitoren,
   α-Glucosidaseinhibitoren,
   β-Agonisten,
   Lipidsenkungsmitteln,
   Antifettsuchtmitteln,
   Vanadat, Vanadiumkomplexen und Peroxovanadiumkomplexen,
   Amylinantagonisten,
   Glucagonantagonisten,
   Gluconeogeneseinhibitoren,
   Somatostatinagonisten und -antagonisten, oder Antilipolysemit"n.

11. Kit nach Anspruch 8, wobei die weitere Verbindung aus Insulin, Biguaniden oder Thiazolidindionen ausgewählt ist.

   a) eine erste pharmazeutische Zusammensetzung, die synergistische Mengen von 1) Glyburide und 2) Milrinone umfasst,
   b) eine zweite pharmazeutische Zusammensetzung, die eine weitere Verbindung, die zur Behandlung von nicht-insulinabhängigem Diabetes mellitus, Insulinresistenz, Syndrom X, Diabetes-Neuropathie, Diabetes-Nephropathie, Diabetes-Retinopathie, Diabetes-Kardiomyopathie, Stein-Leventhal-Syndrom, grauem Star, Hyperglykämie oder beeinträchtigter Glucosetoleranz verwendbar ist, umfasst; und
   c) einen Behälter zur Aufnahme der ersten und zweiten Zusammensetzung umfasst.

   a) eine erste pharmazeutische Zusammensetzung, die Glyburide umfasst;
   b) eine zweite pharmazeutische Zusammensetzung, die Milrinone umfasst, wobei die Mengen von Glyburide und Milrinone synergistische Mengen sind; und
   c) einen Behälter zur Aufnahme der ersten und zweiten Zusammensetzung umfasst.

Revendications

1. Utilisation d'une quantité synergique : 1) de glyburide et 2) de milrinone, pour la production d'un médicament destiné au traitement ou à la prévention du diabète sucré non insulino-dépendant.

2. Utilisation d'une quantité synergique : 1) de glyburide et 2) de milrinone, pour la production d'un médicament destiné au traitement ou à la prévention de la résistance à l'insuline.

3. Utilisation d'une quantité synergique : 1) de glyburide et 2) de milrinone, pour la production d'un médicament destiné au traitement ou à la prévention du syndrome X.

4. Utilisation d'une quantité synergique : 1) de glyburide et 2) de milrinone, pour la production d'un médicament destiné au traitement ou à la prévention de la neuropathie diabétique, de la néphropathie diabétique, de la rétinopathie diabétique, de la myocardopathie diabétique, du syndrome d'ovaire polykystique ou des cataractes.

5. Utilisation d'une quantité synergique : 1) de glyburide et 2) de milrinone, pour la production d'un médicament destiné au traitement ou à la prévention de l'hyperglycémie.

6. Utilisation d'une quantité synergique : 1) de glyburide et 2) de milrinone, pour la production d'un médicament destiné au traitement ou à la prévention de la tolérance entravée au glucose.

7. Composition pharmaceutique comprenant des quantités synergiques de glyburide et de milrinone.

8. Kit pour le traitement du diabète sucré non insulino-dépendant, kit comprenant :

   a) une première composition pharmaceutique comprenant des quantités synergiques 1) de glyburide et 2) de milrinone ;
b) une seconde composition pharmaceutique comprenant un composé supplémentaire utile pour le traitement du diabète sucré non insulino-dépendant ; et
c) un récipient destiné à contenir les première et seconde compositions.

9. Kit suivant la revendication 8, dans lequel le composé supplémentaire est choisi entre :

l’insuline et des analogues d’insuline ;
la GLP-1 (7-37) (insulinotrope) et la GLP-1 (7-36)-NH₂ ;
des biguanides
10. des inhibiteurs de glycogène-phosphorylase ;
des inhibiteurs d’aldose-réductase ;
des antagonistes α2 ;
des imidazolines ;
des glikazones (thiazolidinediones) ;
des agonistes de PPAR-gamma ;
des inhibiteurs d’oxydation des acides gras ;
des inhibiteurs d’α-glucosidase ;
des agonistes-β ;
des agents abaissant les taux de lipides ;
des agents anti-obésité ;
un vanadate, des complexes de vanadium et des complexes de peroxyvanadium ;
des antagonistes d’amylase ;
des antagonistes de glucagon ;
des inhibiteurs de gluconéogènèse ;
des agonistes et antagonistes de somatostatine ; et

des agents antilipolytiques.

10. Kit suivant la revendication 8 dans lequel le composé supplémentaire est choisi entre le LysProinsuline, la GLP-1(7-37) (insulinotrope) et la GLP-1(7-36)-NH₂, la metformine, la phenformine, la buformine, le midaglizole, l’isaglidone, le dériglazone, la darglazone, la rosiglazone, le clomoxir, l’éfaroxan, l’acarbose, le miglitol, l’émiglitate, l’acipimox, le WAG 994, le Symlin™, et le AC2993.

11. Kit suivant la revendication 8, dans lequel le composé supplémentaire est choisi entre l’insuline, des biguanides et des thiazolidinediones.

12. Kit pour le traitement du diabète sucré non insulino-dépendant, de la résistance à l’insuline, du syndrome X, de la neuropathie diabétique, de la néphropathie diabétique, de la rétinopathie diabétique, de la myocardiopathie diabétique, du syndrome d’ovaire polykystique, des cataractes, de l’hyperglycémie ou de la tolérance entravée au glucose, kit comprenant :

a) une première composition pharmaceutique comprenant des quantités synergiques 1) de glyburide et 2) de milrinone ;
b) une seconde composition pharmaceutique comprenant un composé supplémentaire utile pour le traitement du diabète sucré non insulino-dépendant, de la résistance à l’insuline, du syndrome X, de la neuropathie diabétique, de la néphropathie diabétique, de la rétinopathie diabétique, de la myocardiopathie diabétique, du syndrome d’ovaire polykystique, des cataractes, de l’hyperglycémie ou de la tolérance entravée au glucose ; et
c) un récipient destiné à contenir les première et seconde compositions.

13. Kit pour le traitement du diabète sucré non insulino-dépendant, de la résistance à l’insuline, du syndrome X, de la neuropathie diabétique, de la néphropathie diabétique, de la rétinopathie diabétique, de la myocardiopathie diabétique, du syndrome d’ovaire polykystique, des cataractes, de l’hyperglycémie ou de la tolérance entravée au glucose, kit comprenant :

a) une première composition pharmaceutique comprenant du glyburide ;
b) une seconde composition pharmaceutique comprenant de la milrinone ; les quantités de glyburide et de milrinone étant des quantités synergiques ; et
c) un récipient destiné à contenir les première et seconde compositions.
FIG. 1
