Description

[0001] The present invention relates to the purification of a carbonyl-containing 1,3-propanediol composition. More particularly, the present invention relates to treatment of a 1,3-propanediol-containing stream from the manufacture of polytrimethylene terephthalate so as to permit recycle of the 1,3-propanediol to the polymerization process.

[0002] Polytrimethylene terephthalate is a polyester useful in making fibres for carpets and textiles. In the preparation of polytrimethylene terephthalate by the esterification/condensation polymerization of 1,3-propanediol and terephthalic acid, the 1,3-propanediol is initially present in the esterification reaction mixture in a molar excess with respect to the acid. In order to achieve high polymer molecular weight, excess 1,3-propanediol is removed under vacuum and condensed as the polycondensation reaction proceeds.

This condensed 1,3-propanediol stream typically also contains carbonyl-containing by-products of the polymerization process.

[0003] Although it would be desirable to recycle this excess 1,3-propanediol to the polymerization process, the addition of the by-products along with the 1,3-propanediol could result in the accumulation of carbonyl-containing byproducts in the system and interfere with the production of high-quality polyester.

[0004] It is known to purify such byproduct streams by adding a substantial amount of water, acidifying the solution, and then distilling the 1,3-propanediol under basic conditions. It would be desirable to recover purified 1,3-propanediol from the byproduct stream without the necessity of adding large quantities of water to the system.

[0005] It is therefore an object of the present invention to provide a process for preparing polytrimethylene terephthalate in which relatively pure 1,3-propanediol is recovered from the distillate stream and recycled to the polymerization process.

[0006] According to the present invention, there is provided a process for preparing a 1,3-propanediol-based polyester comprising:

(a) contacting, in a polymerization reaction mixture at a temperature within the range of 200 to 300°C under less than atmospheric pressure, terephthalic acid, or an ester thereof, and a molar excess of 1,3-propanediol, to produce a reaction product mixture comprising polytrimethylene terephthalate and a distillate comprising excess 1,3-propanediol, by-product carbonyl compounds and a minor amount of water;
(b) adding a sufficient amount of a base to impart to the distillate a pH higher than 7;
(c) heating the base-containing distillate to a temperature sufficient to distill a major portion of the 1,3-propanediol therefrom; and
(d) passing at least a portion of said distilled 1,3-propanediol to the polymerization reaction mixture as a recycle stream.

[0007] The present invention process involves adding a base to a carbonyl-containing 1,3-propanediol composition. As used herein, "carbonyl" refers to a compound, whether containing the C=O group or not, detected by a method in which total carbonyls are determined by conversion to 2,4-nitrophenylhydrazone derivatives and measured colorimetrically, such as ASTM E411-70. The source of such carbonyl species can be acetals, aldehydes or ketones.

[0008] The carbonyl-containing 1,3-propanediol composition is a distillate stream from the preparation of polytrimethylene terephthalate. As used herein, "1,3-propanediol-based polyester" refers to a polyester prepared by reacting at least one diol with at least one aromatic diacid (or alkyl ester thereof) in which at least 80 mole percent of the diol is 1,3-propanediol. "Polytrimethylene terephthalate" refers to such a polyester in which at least 80 mole percent of the diacid is terephthalic acid (or an alkyl ester thereof). Other diols may include, for example, ethylene glycol, diethylene glycol, 1,4-cyclohexanone dimethanol, bis(3-hydroxypropyl)ether and 1,4-butanediol, and other diacids may include, for example, isophthalic acid and 2,6-naphthalene dicarboxylic acid. The condensation polymerization of polytrimethylene terephthalate usually generates as much as about 4 mole percent of bis(3-hydroxypropyl)ether which, in effect, becomes a comonomer and is incorporated into the polyester chain.

[0009] Polytrimethylene terephthalate is prepared by the polycondensation reaction of the 1,3-propanediol with terephthalic acid (or an alkyl ester thereof) under vacuum and at a temperature within the range of 200 to 300°C. The diol(s) are added to the polymerization reaction mixture in a molar excess, of preferably 5 to 50%, with respect to the acid. As the polycondensation reaction proceeds, the excess diol is removed under vacuum and condensed. The condensed stream typically contains, in addition to 70 wt% or more diol(s), polymerization byproducts such as allyl alcohol, acrolein and other carbonyl compounds, acetals, alcohols, glycol ethers, diacids, polyester oligomers and additives, and no more than 20wt%, more typically 1-20wt%, water. Further 1,3-propanediol can be added if needed to adjust the water concentration to this range. The carbonyl content (as C=O) of the distillate stream can be at least 500 ppm, more typically in the range from 500 to 2500ppm (wt), depending upon the purity of the starting 1,3-propanediol and the polymerization reaction conditions. The pH of the stream is typically within the range of 3 to 6. The diol product of the invention treatment process preferably contains less than 300 ppm (wt) carbonyl, most preferably less than 200
A base is added to the 1,3-propanediol-containing composition in an amount sufficient to raise the pH thereof to a value greater than 7, preferably 7.5 to 14, most preferably within the range of 8 to 10. If desired, the base can be added in increments over the course of the purification process. The amount of base added is nominally the amount needed to neutralize acidic species present in the condensed stream plus any amount needed to reach the target pH. However, additional base may be needed, particularly if the stream contains soluble or suspended polyester adducts or oligomers, since reaction of the base with these oligomers or other impurities may consume base during the purification process. If the stream contains solid polymerization by-products, it is preferable to remove such solids by, for example, filtration prior to addition of the base to the liquid mixture.

The addition of base is preferably achieved without raising the water content of the base-containing distillate above 20 wt%.

Suitable bases for the purification treatment are typically inorganic bases such as the alkali and alkaline earth hydroxides, carbonates and bicarbonates. Preferred bases are sodium and potassium hydroxides, most preferably sodium hydroxide. Organic bases such as amines are to be avoided.

The base-containing condensed stream is optionally further treated with a borohydride represented by the formula MBH x Y y, in which M is an alkali metal cation or a tetraalkylammonium cation, Y is a ligand, x is at least 1, and x+y = 4, with x = 4 and y = 0 most preferred. Examples of such borohydrides include the metal tetrahydridoborates such as lithium borohydride, potassium borohydride, sodium borohydride and rubidium borohydride; metal organoborohydrides such as lithium trimethylborohydride, lithium triethylborohydride, lithium tributylborohydride, potassium tri-isopropylborohydride, potassium tri-sec-butylborohydride, potassium triphenylborohydride, sodium triacetoxycarbonylborohydride, sodium tri-isopropylborohydride, sodium tri-sec-butylborohydride, sodium triphenylborohydride; tetraalkylammonium borohydrides such as tetramethylammonium diborohydride, tetraethylammonium diborohydride and tetrabutylammonium diborohydride. Potassium borohydride, sodium borohydride and tetraethylammonium borohydrides are preferred, most preferably sodium borohydride or tetraethylammonium borohydride. If desired, the borohydride can be used in supported form on basic alumina, silica gel and the like.

The amount of borohydride added to the condensed stream will generally be that amount which provides 0.2 to 20 gram atoms of hydrogen atoms per mole of carboxyls, as defined herein, in the stream. In the case of the preferred potassium, sodium and tetraethylammonium borohydrides, the amount will generally range from 0.05 to 5 moles, preferably 0.1 to 1 mole, of borohydride per mole of carboxyl present in the stream.

Because borohydrides are generally unstable under acidic conditions, the borohydride is preferably added after at least a portion of the base has been added to the condensed stream. If desired, a small quantity of water can be added to the condensed stream for a total water content of up to 20 wt% to facilitate dissolution of the more polar borohydrides such as sodium and potassium borohydrides.

Following the addition of borohydride and prior to distillation, the condensed stream may optionally be heated and maintained at a temperature within the range of 40 to 100 °C for a few minutes to several hours, preferably a time within the range of 15 minutes to 24 hours. Preferably the base-containing distillate is maintained at a temperature less than that sufficient for distillation of the 1,3-propanediol therefrom for at least 1 hour prior to such distillation. Alternatively, the condensed stream may be heated directly to the temperature at which distillation of the 1,3-propanediol will be carried out.

Distillation is typically carried out by boiling off water, if present, and other low-boiling components at atmospheric or reduced pressure, and then distilling off 1,3-propanediol, preferably at reduced pressure less than 200 mbar and a temperature within the range of 60 to 160 °C to avoid excessive heating of the 1,3-propanediol.

The present invention can be practised as a series of batch, semi-batch, semi-continuous or continuous processes.

The purified 1,3-propanediol can be used, for example, to prepare condensation polymers and copolymers. The purified 1,3-propanediol is particularly useful as a monomer recycle stream for addition to a fresh 1,3-propanediol feed to polytrimethylene terephthalate manufacture.

Example 1

Purification of 1,3-Propanediol-Containing Stream.

A flask with magnetic stir bar was charged with 250g of a vacuum distillate recovered from preparation of polytrimethylene terephthalate having (after filtration to remove a minor amount of solids) about 15 wt% water, a pH of about 3.6, 1190 ppm (wt) carboxyls (as C=O), 1370 ppm acrolein by GC, about 5 wt% allyl alcohol, minor amounts of other glycols, about 0.7 wt% terephthalic acid (after hydrolysis of any soluble terephthalic esters), about 10-15 ppm iron and about 80 wt% 1,3-propanediol. The pH of this solution was adjusted to 8.96 by addition of about 10 ml IN
solution of sodium hydroxide. The solution was heated in an oil bath under reduced pressure and distilled through a 30cm Vigreaux distillation column and chilled condenser to provide a forecut (69g) and a major cut (141g, b.p. 127°C), the latter collected at an oil bath temperature of about 150°C and 3.5-6.5 kPa (35-65 mbar). Carbonyl analyses of the fractions-- forecut, major cut and bottoms (41g)-- are shown in Table 1.

Example 2

Purification of 1,3-Propanediol-Containing Stream.

[0021] The procedure of Example 1 was repeated, except that, after adjustment of the pH, the mixture was allowed to stand at room temperature for about 67 hours, after which the pH had dropped to about 7.9. Additional sodium hydroxide was added to bring the pH to about 8.7 and the mixture was distilled. A water-rich cut was taken and then the forecut and major cuts were collected. Carbonyl analyses are shown in Table 1.

Example 3

Purification of 1,3-Propanediol-Containing Stream.

[0022] The procedure of Example 2 was repeated (without pH readjustment), except that the 1,3-propanediol stream was a vacuum distillate recovered from polytrimethylene terephthalate preparation having a pH (after filtration to remove solids) of 3.9, 773 ppm carbonyl, less than 10 ppm acrolein, 440 ppm allyl alcohol, minor amounts of other glycols, about 0.5wt% terephthalic acid (after hydrolysis), at least about 94wt% 1,3-propanediol, and less than about 1wt% water. This distillate had been stored for several months at ambient conditions. Carbonyl analyses are shown in Table 1.

Example 4

Purification of 1,3-Propanediol-Containing Stream.

[0023] The procedure of Example 1 was repeated, except that the stream was diluted with about 175g deionized water to make a 50wt% 1,3-propanediol solution prior to being adjusted to 9.1 pH with NaOH. A water cut was collected before the forecut. Carbonyl analyses are shown in Table 1. The example shows that dilution with water does not substantially improve the purification in that the carbonyl content of the major fraction obtained is similar to that obtained in Example 1.

Example 5

Purification of 1,3-Propanediol-Containing Stream.

[0024] The procedure of Example 4 was repeated using the 1,3-propanediol stream described in Example 3 and 250g water to make the 50wt% solution. Carbonyl analyses are shown in Table 1.

Example 6 (Comparative)

Recovery of 1,3-Propanediol by Distillation Alone.

[0025] This comparative experiment was performed by distilling the distillate stream described in Example 3 by the procedure described in Example 1 but without treatment with a base. The major cut of 1,3-propanediol showed significantly higher levels of carbonyls than those of Examples 1-5. Carbonyl analyses are shown in Table 1.

Example 7 (Comparative)

Recovery of 1,3-Propanediol by Distillation Alone.

[0026] This comparative experiment was performed by distilling the distillate stream described in Example 1 by the method of Example 1, but without treatment with a base. The major cut of 1,3-propanediol showed significantly higher levels of carbonyls than those of Examples 1-5.

Example 8 (Comparative)

Recovery of 1,3-Propanediol by Distillation of a Dilute Stream.

[0027] This comparative experiment was performed as described in Example 6, except that the 1,3-propanediol stream was diluted with deionized water to make a solution of about 50wt% 1,3-propanediol, and this aqueous solution was adjusted to a pH of about 3 by addition of a small amount of p-toluenesulfonic acid. The solution was heated at 45-55°C for about one hour, followed by distillation. The major cut contained a higher level of carbonyls than obtained in Example 3.

Example 9

Purification of 1,3-Propanediol-Containing Stream with Added Borohydride

[0028] A flask was charged with 250g of the 1,3-propanediol stream described in Example 3 and the pH was adjusted to 9 by addition of iN NaOH. After addition of tetraethylammonium borohydride (1g, 6.9 mmol), the reaction mixture was degassed with nitrogen and heated to 75°C for 50 minutes under nitrogen purge. The solution was then distilled as in the previous examples. The results are shown in Table 1.

Example 10

Purification of 1,3-Propanediol-Containing Stream with Added Borohydride

[0029] The procedure of Example 9 was repeated, except that 212.5g of the 1,3-propanediol stream was mixed with 37.5g deionized water to give a solution of about 85wt% 1,3-propanediol in water containing about 1.9 mmol carbonyls. After adjustment of the pH to 9.5 with 1N NaOH, 0.23g (6.1 mmol) sodium borohydride was added, the reaction mixture was heated to 70°C for about one hour, and the mixture was distilled. Carbonyl analyses are shown in Table 1.

Example 11

Purification of 1,3-Propanediol-Containing Stream with Added Borohydride

[0030] The procedure of Example 9 was repeated, except that 250g of the 1,3-propanediol stream described in Example 1 was used (about 10.6 mmol carbonyls), the adjusted pH was 9.2, and 0.40g (10.6 mmol) sodium borohydride was added. Carbonyl analyses are shown in Table 1.
Example 12

Purification of 1,3-Propanediol-Containing Stream with Added Borohydride

[0031] The procedure of Example 11 was repeated, except that the pH was adjusted to 8.6 and 0.8g (21 mmol) sodium borohydride was added. Carbonyl analyses are shown in Table 1.

Example 13 (Comparative)

Purification of 1,3-Propanediol-Containing Stream with Added Borohydride

[0032] The procedure of Example 9 was repeated, except that there was no adjustment of pH prior to addition of 1g (6.9 mmoles) borohydride. The reaction mixture turned black while it was being degassed. After heating for an hour at 75°C, the black mixture was distilled. Although the major cut had low carbonyls, the formation of the black color suggests decomposition of the borohydride or other unwanted side reaction.

[0033] As can be seen from the results of Table 1, the use of base and borohydride gave similar or somewhat lower concentrations of carbonyls in the major cuts compared to the use of base alone. In the case of the fresher distillate, the carbonyl levels measured in the forecuts and bottoms were less with base/borohydride than for comparable runs using base alone, which would be an advantage for recycle of one or both of these fractions.

[0034] Doubling the amount of borohydride (Example 12) did not substantially reduce the total amount of carbonyls (compare Example 11), which demonstrates that a large proportion of the "carbonyls" in the 1,3-propanediol are not subject to reduction by hydrides, such as would be the case for acetals. Thus, the base treatment with distillation is an effective procedure even in the absence of the borohydride.

Example 14

Polymerization of Treated 1,3-Propanediol

[0035] The purified 1,3-propanediol (major cuts) from Examples 1 and 11 was used to prepare polytrimethylene terephthalate oligomer. A 600ml stainless steel pressure reactor fitted with a distillation column, condenser and collection vessel was charged with 66.6g of 1,3-propanediol (0.88 mole) and 103.9g terephthalic acid (0.63 mole). The reactor was pressurized to 345-552 kPa (50-80 psi) with nitrogen, the pressure was released five times to degas, then the vessel was repressurized to 138 kPa (20 psi) and heated to 250°C. For the first two hours, the pressure was maintained near 345 kPa (50 psi) and was then lowered in 69 kPa (10 psi) increments each hour thereafter. After a total of about 6 hours, any remaining pressure was released, and the aqueous distillate was collected, weighed and analyzed by GC. The molten oligomer was poured into a pan and cooled.

The results are shown in Table 2.

[0036] The oligomer (140g) and 0.09g titanium butoxide catalyst were charged to a 500-ml 3-neck flask. The flask was degassed with nitrogen, evacuated to about 20 kPa (200 mbar) with a small nitrogen sweep, heated in an oil bath to 260°C, and stirred at about 20 rpm. The pressure was reduced to about 0.1 kPa (1 mbar). After 3 hours, the reaction mixture was cooled and the polymer was isolated. Results are shown in Table 2.

[0037] As can be seen from the results, the purified 1,3-propanediol (from Examples 1 and 11) produced less acrolein in the aqueous distillate, less acrolein and total carbonyls in the 1,3-propanediol distillate, and higher molecular weight than unpurified commercial-grade 1,3-propanediol.

Claims

1. A process for preparing a 1,3-propanediol-based polyester comprising:
   (a) contacting, in a polymerization reaction mixture at a temperature within the range of 200 to 300°C under
   less than atmospheric pressure, terephthalic acid, or an ester thereof, and a molar excess of 1,3-propanediol,
   to produce a reaction product mixture comprising polytrimethylene terephthalate and a distillate comprising
   excess 1,3-propanediol, by-product carbonyl compounds and a minor amount of water;
   (b) adding a sufficient amount of a base to impart to the distillate a pH higher than 7;
   (c) heating the base-containing distillate to a temperature sufficient to distill a major portion of the 1,3-propan-
   ediol therefrom; and
   (d) passing at least a portion of said distilled 1,3-propanediol to the polymerization reaction mixture as a recycle
   stream.

2. The process according to claim 1 wherein the base is selected from alkali and alkaline earth hydroxides, carbonates
   and bicarbonates.

3. The process according to claim 1 or 2 which further comprises removing any solids from the distillate prior to
   addition of the base.

4. The process according to claim 1, 2 or 3 wherein the distillate in step (a) contains no more than 20 wt% water.

5. The process according to claim 4 wherein, in step (b), said addition of base is achieved without raising the water
   content of the base-containing distillate above 20wt%.

6. The process according to claim 4 or 5 wherein step (a) comprises adding 1,3-propanediol to the distillate to reduce
   the water content thereof to no more than 20 wt%.

7. The process according to any one of the preceding claims which further comprises adding a borohydride of the
   formula MBHₓYᵧ, in which M is an alkali metal or tetraalkylammonium cation, y is a ligand, x is at least 1 and x+y=4,
   to the base-containing distillate prior to distillation of 1,3-propanediol therefrom.

8. The process according to claim 7 wherein the borohydride is selected from the group consisting of potassium
   borohydride, sodium borohydride and tetraalkylammonium borohydride.

9. The process according to claim 7 or 8 in which the borohydride is added in an amount within the range of 0.05 to
   5 moles per mole of carbonyl.

10. The process according to any one of the preceding claims in which the 1,3-propanediol-based polyester is polyt-
    rimethylene terephthalate.

Patentansprüche

1. Verfahren zur Herstellung eines Polyesters auf 1,3-Propandiolbasis, umfassend:
   (a) Inkontaktbringen von Terephthalsäure oder eines Esters hiervon mit einem molaren, Überschuß an 1,3-Pro-
   pandiol in einem Polymerisationsreaktionsgemisch bei einer Temperatur im Bereich von 200 bis 300°C unter
   einem unter dem Atmosphärendruck liegenden Druck zur Ausbildung eines Polytrimethylene terephthalat um-
   fassenden Reaktionsproduktgemisches und eines überschüssiges 1,3-Propandiol, ein Nebenprodukt aus Car-
   bonylverbindungen und eine kleine Menge Wasser umfassenden Destillats;
   (b) Zusetzen einer ausreichenden Menge einer Base, um dem Destillat einen pH-Wert von über 7 zu erteilen;
   (c) Erhitzen des basenhaltigen Destillats auf eine ausreichende Temperatur, um einen Hauptteil des 1,3-Pro-
   pandios daraus abzudestillieren; und
   (d) Führen wenigstens eines Teils dieses abdestillierten 1,3-Propandiols zu dem Polymerisationsreaktionsge-
       misch als ein Rücklaufstrom.

2. Verfahren nach Anspruch 1, worin die Base unter Alkaliund Erdalkalihydroxiden, -carbonaten und -bicarbonaten
ausgewählt wird.

3. Verfahren nach Anspruch 1 oder 2, das zusätzlich ein Abtrennen etwaiger Feststoffe aus dem Destillat vor dem Zusetzen der Base umfaßt.

4. Verfahren nach Anspruch 1, 2 oder 3, worin das Destillat in Stufe (a) nicht über 20 Gew.-% Wasser enthält.

5. Verfahren nach Anspruch 4, worin in Stufe (b) die Basenzugabe ohne Erhöhen des Wassergehaltes des basenhältigen Destillats auf über 20 Gew.-% erfolgt.

6. Verfahren nach Anspruch 4 oder 5, worin die Stufe (a) ein Zusetzen von 1,3-Propandiol zu dem Destillat zur Verringerung dessen Wassergehaltes auf nicht über 20 Gew.-% umfaßt.

7. Verfahren nach einem der vorstehenden Ansprüche, das weiterhin ein Zusetzen eines Borhydrids der Formel MBH_y^xY^y, worin M ein Alkalimetall- oder Tetraalkylammoniumkation bedeutet, Y einen Liganden bezeichnet; x wenigstens 1 ist und x+y=4 bedeutet, zu dem basenhältigen Destillat vor dem Destillieren von 1,3-Propandiol daraus umfaßt.

8. Verfahren nach Anspruch 7, worin das Borhydrid aus der aus Kaliumborhydrid, Natriumborhydrid und Tetraalkylammoniumborhydrid bestehenden Gruppe ausgewählt wird.

9. Verfahren nach Anspruch 7 oder 8, worin das Borhydrid in einer Menge im Bereich von 0,05 bis 5 Mol pro Mol Carboxyl zugesetzt wird.

10. Verfahren nach einem der vorstehenden Ansprüche, worin der Polyester auf 1,3-Propandiolbasis Polytrimethylenterephthalat ist.

Revendications

1. Procédé de préparation d’un polyester à base de 1,3-propanediol comprenant :
   (a) la mise en contact, dans un mélange de réaction de polymérisation à une température allant de 200 à 300°C sous une pression inférieure à la pression atmosphérique, d’acide téréphtalique, ou d’un ester de celui-ci, et d’un excès molaire de 1,3-propanediol, pour produire un mélange de produits de réaction comprenant du polytriméthylène téréphtalate et un distillat comprenant un excès de 1,3-propanediol, des composés carbonylés comme sous-produits et une petite quantité d’eau; (b) l’addition d’une quantité suffisante d’une base pour conférer au distillat un pH supérieur à 7; (c) le chauffage du distillat contenant la base à une température suffisante pour en séparer par distillation une majeure partie du 1,3-propanediol; et (d) le passage d’au moins une partie dudit 1,3-propanediol distillé vers le mélange de réaction de polymérisation sous la forme d’un courant de recyclage.

2. Procédé suivant la revendication 1, dans lequel la base est choisie parmi les hydroxydes, carbonates et bicarbonates alcalins et alcalino-terreux.

3. Procédé suivant l’une ou l’autre des revendications 1 et 2, qui comprend de plus la séparation des éventuelles matières solides du distillat avant l’addition de la base.

4. Procédé suivant l’une quelconque des revendications 1, 2 et 3, dans lequel le distillat dans l’étape (a) ne contient pas plus de 20% en poids d’eau.

5. Procédé suivant la revendication 4, dans lequel, dans l’étape (b), l’addition de base précitée est réalisée sans élever la teneur en eau du distillat contenant la base au-dessus de 20% en poids.

6. Procédé suivant l’une ou l’autre des revendications 4 et 5, dans lequel l’étape (a) comprend l’addition de 1,3-propanediol au distillat pour abaisser la teneur en eau de celui-ci à pas plus de 20% en poids.
7. Procédé suivant l'une quelconque des revendications précédentes, qui comprend de plus l'addition d'un borohydrure de la formule \( M \text{BH}_x Y_y \), dans laquelle \( M \) est un cation de métal alcalin ou de tétraalkylammonium, \( y \) est un ligand, \( x \) est au moins 1 et \( x+y=4 \), au distillat contenant la base avant la séparation par distillation de 1,3-propandiol.

8. Procédé suivant la revendication 7, dans lequel le borohydrure est choisi dans le groupe comprenant le borohydrure de potassium, le borohydrure de sodium et les borohydrures de tétraalkylammonium.

9. Procédé suivant l'une ou l'autre des revendications 7 et 8, dans lequel le borohydrure est ajouté en une quantité allant de 0,05 à 5 moles par mole de carbone.

10. Procédé suivant l'une quelconque des revendications précédentes, dans lequel le polyester à base de 1,3-propandiol est du polytriméthylène téréphthalate.
