Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

[0001] The present invention is concerned with the use of a fire retardant in preparing rigid foams and flexible foams and with compositions comprising such fire retardant.

[0002] The use of fire retardants in preparing polyurethane foams has been widely described. J02153967 discloses a polyurethane foam containing expandable graphite and a fire-retardant agent such as tris(2-chloroethyl)phosphate. EP-A-192888 discloses a polyurethane foam containing a fire-retardant agent comprising expandable graphite and optionally other compounds such as phosphorous compounds. J51009197 discloses a polyurethane foam containing a fire-retardant agent comprising e.g. tricresylphosphate, where the foam further comprises carbonaceous fibers.

[0003] Further conventional flexible polyurethane foams are widely known. Such foams show a relatively high resilience (ball rebound), a relatively low modulus, a relatively high sag factor and a relatively low hysteresis loss. Such foams further show a major glass-rubber transition below ambient temperature, generally in the temperature range of -100°C to -10°C. The commonly applied relatively high molecular weight polyether and polyester polyols in such foams are responsible for the sub-ambient glass transition temperature (TgS). These polyether and polyester polyols are often referred to as soft segments. Above TgS the foam displays its typical flexible properties until softening and/or melting with increasing temperature and at TgS/TmS again a substantial decrease of the modulus may take place. A way of expressing the presence of TgS is to determine the ratio of the Young's storage modulus E' at -100°C to +25°C as per Dynamic Mechanical Thermal Analysis (DMTA measured according to ISO/DIS 6721-5). For conventional flexible polyurethane foams the

\[
\frac{E'_{-100°C}}{E'_{+25°C}} \text{ ratio is at least } 25.
\]

[0004] Another feature of TgS by DMTA (ISO/DIS 6721-5) is that for conventional flexible polyurethane foams the maximum value of the

\[
\text{ratio of } \frac{\text{Young's loss modulus } E^*}{\text{Young's storage modulus } E'(\tan \delta_{\text{max}})}
\]

over the -100°C/+25°C temperature range varies from 0.20 - 0.80 in general. The Young's loss modulus E* is measured by DMTA (ISO/DIS 6721-5) as well.

[0005] In patent application PCT/EP9601594 a completely new class of flexible polyurethane foams is described such foams having no major glass-rubber transition between -100°C and +25°C. In more quantitative terms these foams show a ratio E'_{-100°C}/E'_{+25°C} of 1.3 to 15.0, preferably of 1.5 to 10 and most preferably of 1.5 to 7.5. The tan δmax over the -100°C to +25°C temperature range is below 0.2.

[0006] PCT/EP9806888 discloses a process substantially according to the one of PCT/EP9601594, carried out in the presence of a fire retardant wherein the fire retardant is selected from 1) polybrominated diphenyl ethers; 2) dialkyl esters of polybrominated phthalic acid; 3) compounds of formula P(O)XYZ, wherein X, Y and Z are independently selected from the groups -R and -OR wherein R is an aryl or aralkyl group having 6-12 and preferably 6-10 carbon atoms; 4) mixtures of the compounds 1, 2 and 3 or with mixtures of the compounds 1, 2 and 3. The apparent core density of such foams may range from 4-30 kg/m³ and preferably ranges from 4-20 kg/m³ (measured according to ISO/DIS845). Such foams are made by crushing a rigid foam.

[0007] DE 2428307 discloses polyisocyanurate foams made from polyester polyols and using alkylphosphates together with graphite.

[0008] DE 19702760 is related to the making of rigid polyurethane foams using alkylphosphates and graphite.

[0009] In the context of the present application hereinafter a flexible polyurethane foam is a crushed foam having a ball rebound (measured according to ISO 8307) of at least 40%, preferably at least 50% and most preferably 55-85% in at least one of the three dimensional directions and a sag factor (CLD 65/25) of at least 2.0 (measured according to ISO 3386/1). Preferably such flexible foams have a Young's storage modulus at 25°C of at most 500 kPa, more preferably at most 350 kPa and most preferably between 10 and 200 kPa (Young's storage modulus measured by DMTA according to ISO/DIS 6721-5). Further, such flexible foams preferably have a sag factor (CLD 65/25) of at least
3.5 and most preferably 4.5-10 (measured according to ISO 3386/1). Still further such flexible foams preferably have a CLD hysteresis loss (ISO 3386/1) of below 55%, more preferably below 50% and most preferably below 45%.

[0010] In the context of the present patent application hereinafter a rigid polyurethane foam is an uncrushed foam having a ball rebound measured in the direction of foam rise of less than 40% (ISO 8307 with the proviso that no preflex conditioning is applied, that only one rebound value per sample is measured and that test pieces are conditioned at 23°C ± 2°C and 50 ± 5% relative humidity) and/or having a CLD 65/25 sag factor measured in the direction of foam rise of less than 2.0 (ISO 3386/1 with the proviso that the sag factor is determined after the first load - unload cycle); these properties both being measured at a core density of the foam of 3-27 kg/m³ (ISO 845). Preferably the ratio $E'_{25°C}/E'_{-100°C}$ of such a rigid foam is 1.3-15. If in the present application ISO 8307 and ISO 3386/1 are mentioned in relation to rigid foams they refer to the tests as described above including the provisos.

[0011] In the context of the present invention the following terms have the following meaning:

1) isocyanate index or NCO index or index:

the ratio of NCO-groups over isocyanate-reactive hydrogen atoms present in a formulation, given as a percentage:

$$\frac{[\text{NCO}]\times 100}{[\text{active hydrogen}]} \text{(%).}$$

In other words the NCO-index expresses the percentage of isocyanate actually used in a formulation with respect to the amount of isocyanate theoretically required for reacting with the amount of isocyanate-reactive hydrogen used in a formulation.

It should be observed that the isocyanate index as used herein is considered from the point of view of the actual foaming process involving the isocyanate ingredient and the isocyanate-reactive ingredients. Any isocyanate groups consumed in a preliminary step to produce modified polyisocyanates (including such isocyanate-derivatives referred to in the art as quasi or semi-prepolymers and prepolymer(s) or any active hydrogens consumed in a preliminary step (e.g. reacted with isocyanate to produce modified polyols or polyamines) are not taken into account in the calculation of the isocyanate index. Only the free isocyanate groups and the free isocyanate-reactive hydrogens (including those of the water) present at the actual foaming stage are taken into account.

2) The expression "isocyanate-reactive hydrogen atoms" as used herein for the purpose of calculating the isocyanate index refers to the total of active hydrogen atoms in hydroxyl and amine groups present in the reactive compositions; this means that for the purpose of calculating the isocyanate index at the actual foaming process one hydroxyl group is considered to comprise one reactive hydrogen, one primary amine group is considered to comprise one reactive hydrogen and one water molecule is considered to comprise two active hydrogens.

3) Reaction system : a combination of components wherein the polyisocyanates are kept in one or more containers separate from the isocyanate-reactive components.

4) The expression "polyurethane foam" as used herein refers to cellular products as obtained by reacting polyisocyanates with isocyanate-reactive hydrogen containing compounds, using foaming agents, and in particular includes cellular products obtained with water as reactive foaming agent (involving a reaction of water with isocyanate groups yielding urea linkages and carbon dioxide and producing polyurea-urethane foams) and with polyols, aminoalcohols and/or polyamines as isocyanate-reactive compounds.

5) The term "average nominal hydroxyl functionality" is used herein to indicate the number average functionality (number of hydroxyl groups per molecule) of the polyol or polyol composition on the assumption that this is the number average functionality (number of active hydrogen atoms per molecule) of the initiator(s) used in their preparation although in practice it will often be somewhat less because of some terminal unsaturation.

6) The word "average" refers to number average unless indicated otherwise.

7) $pK_a$ refers to the strength of a protolyte compared to that of water ($pK_a = -\log K_a$ wherein $K_a$ is the dissociation constant of the acid or the salt).

[0012] The foams according to the present invention are prepared by reacting a polyisocyanate (1), an isocyanate-
reactive compound (2), said compound (2) having an average equivalent weight of at most 374 and an average number of isocyanate-reactive hydrogen atoms of from 2 to 8, an isocyanate-reactive compound (3), said compound (3) having an average equivalent weight of more than 374 and an average number of isocyanate-reactive hydrogen atoms of from 2 to 6 and water in the presence of a catalyst and in the presence of a fire retardant to prepare a rigid polyurethane foam and by crushing this rigid polyurethane foam to prepare a flexible polyurethane foam.

[0013] Further the present invention is concerned with a polyisocyanate composition comprising the fire retardants. More in particular the foams according to the present invention are prepared by reacting a polyisocyanate (1), a polyol (2) having a hydroxyl number of at least 150 mg KOH/g and an average nominal hydroxyl functionality of from 2 to 8, a polyol (3) having a hydroxyl number of from 10 to less than 150 mg KOH/g and an average nominal hydroxyl functionality of from 2 to 6 and water in the presence of a catalyst and a fire retardant to prepare a rigid polyurethane foam and by crushing this rigid polyurethane foam to prepare a flexible polyurethane foam.

[0014] Suitable organic polyisocyanates for use in the process of the present invention include any of those known in the art for the preparation of rigid polyurethane foams, like aliphatic, cycloaliphatic, araliphatic and, preferably, aromatic polyisocyanates, such as toluene diisocyanate in the form of its 2,4- and 2,6-isomers and mixtures thereof and diphenylmethane diisocyanate in the form of its 2,4′-; 2,2′- and 4,4′-isomers and mixtures thereof, the mixtures of diphenylmethane diisocyanates (MDI) and oligomers thereof having an isocyanate functionality greater than 2 known in the art as "crude" or polymeric MDI (polymethylene polyphenylene polyisocyanates), the known variants of MDI comprising urethane, allophanate, urea, biuret, carbodiimide, uretonimine and/or isocyanurate groups.

[0015] Mixtures of toluene diisocyanate and diphenylmethane diisocyanate and/or polymethylene polyphenylene polyisocyanates may be used. Most preferably polyisocyanates are used which have an average isocyanate functionality of 2.1-3.0 and preferably of 2.2-2.8.

[0016] Preferably MDI, crude or polymeric MDI and/or liquid variants thereof are used said variants being obtained by introducing uretonimine and/or carbodiimide groups into said polyisocyanates. such a carbodiimide and/or uretonimine modified polyisocyanate having an NCO value of at least 20% by weight, and/or by reacting such a polyisocyanate with one or more polyols having a hydroxyl functionality of 2-6 and a molecular weight of 62-500 so as to obtain a modified polyisocyanate having an NCO value of at least 20% by weight.

[0017] Isocyanate-reactive compounds (2) include any of those known in the art for that purpose like polyamines, aminoalcohols and polyols. Of particular importance for the preparation of the rigid foams are polyols and polyol mixtures having hydroxyl numbers of at least 150 mg KOH/g and an average nominal hydroxyl functionality of from 2 to 6. Suitable polyols have been fully described in the prior art and include reaction products of alkylene oxides, for example ethylene oxide and/or propylene oxide, with initiators containing from 2 to 8 active hydrogen atoms per molecule. Suitable initiators include : polyols, for example ethylene glycol, diethylene glycol, propylene glycol, dipropylene glycol, butane diol, glycerol, trimethylolpropane, triethanolamine, pentaerythritol, sorbitol and sucrose; polyamines, for example ethylene diamine, tolylene diamine, diaminodiphenylmethane and polymethylene polyphenylene polyamines; and aminoalcohols, for example ethanolamine and diethanolamine; and mixtures of such initiators. Other suitable polyols include polyesters obtained by the condensation of appropriate proportions of glycols and higher functionality polyols with polycarboxylic acids. Still further suitable polyols include hydroxyl terminated polythioethers, polyamides, polyesteramides, polycarbonates, polyacetals, polyolefins and polysiloxanes. Preferred polyols are the polyether polyols comprising ethylene oxide and/or propylene oxide units and most preferably polyoxyethylene polyoxypropylene polyols having an oxyethylene content of at least 10% and preferably 10-85% by weight. Other polyols which
may be used comprise dispersions or solutions of addition or condensation polymers in polyols of the types described above. Such modified polyols, often referred to as "polymer" polyols have been fully described in the prior art and include products obtained by the in situ polymerisation of one or more vinyl monomers, for example styrene and acrylonitrile, in polymeric polyols, for example polyether polyols, or by the in situ reaction between a polyisocyanate and an amino- or hydroxy-functional compound, such as triethanolamine, in a polymeric polyol.

The polymer modified polyols which are particularly interesting in accordance with the invention are products obtained by in situ polymerisation of styrene and/or acrylonitrile in polyoxyethylene polyoxypropylene polyols and products obtained by in situ reaction between a polyisocyanate and an amino or hydroxy-functional compound (such as triethanolamine) in a polyoxyethylene polyoxypropylene polyol. Polyoxyalkylene polyols containing from 5 to 50% of dispersed polymer are particularly useful. Particle sizes of the dispersed polymer of less than 50 microns are preferred. Mixtures of such isocyanate-reactive compounds may be used as well. Most preferably polyols are used which do not comprise primary, secondary or tertiary nitrogen atoms.

The relative amount of isocyanate-reactive compound (2) and (3) or polyol (2) and (3) may vary widely and preferably ranges from 0.1:1 to 4:1 (w:w).

In order to prepare a foam water is used as a blowing agent. However if the amount of water is not sufficient to obtain the desired density of the foam any other known way to prepare polyurethane foams may be employed additionally, like the use of reduced or variable pressure, the use of a gas like air, N₂ and CO₂, the use of more conventional blowing agents like chlorofluorocarbons, hydrofluorocarbons, hydrocarbons and fluorocarbons, the use of other reactive blowing agents, i.e. agents which react with any of the ingredients in the reacting mixture and due to this reaction liberate a gas which causes the mixture to foam and the use of catalysts which enhance a reaction which leads to gas formation like the use of carbodiimide-formation-enhancing catalysts such as phospholene oxides. Combinations of these ways to make foams may be used as well. The amount of blowing agent may vary widely and primarily depends on the desired density. Water may be used as liquid at below-ambient, ambient or elevated temperature and as steam.

A preferred combination of blowing agent is water and CO₂ wherein the CO₂ is added to the ingredients for making the foam in the mixing head of a device for making the foam, to one of the isocyanate-reactive ingredients and preferably to the polyisocyanate before the polyisocyanate is brought into contact with the isocyanate-reactive ingredients.

Per 100 parts by weight of polyisocyanate (1), isocyanate-reactive compound (2) and compound (3) or polyol (2) and polyol (3) and water, preferably the amount of compound (2) or polyol (2) ranges from 2-20 parts by weight, the amount of compound (3) or polyol (3) ranges from 5-35 parts by weight and the amount of water ranges from 1 to 17 parts by weight, the remainder being polyisocyanate. Most preferably these amounts are 55-80, 3-20, 10-30 and 2-6 parts by weight for the polyisocyanate, polyol (2), polyol (3) and water respectively. This encompasses another aspect of the invention : if a cyclic polyisocyanate and more in particular an aromatic polyisocyanate and most in particular an MDI or polymethylenepolyphenylene polyisocyanate is used the content of cyclic and more in particular of aromatic residues in the flexible foam is relatively high as compared to conventional flexible polyurethane foams. The foams according to the invention preferably have a content of benzene rings, derived from aromatic polyisocyanates, which is 30 to 56 and most preferably 35 to 50% by weight based on the weight of the foam. Since polyols, polymer polyols, fire retardants, chain extenders and/or fillers which contain benzene rings may be used, the overall benzene ring content of the flexible foam may be higher and preferably ranges from 30 to 70 and most preferably from 35 to 65% weight as measured by calibrated Fourier Transform Infra Red Analysis.

The present invention is more in particular concerned with a process for preparing rigid polyurethane foams by reacting a polyisocyanate (1), a polyether polyol (2) having a hydroxyl number of at least 150 mg KOH/g and an average nominal hydroxyl functionality of from 2 to 8, a polyether polyol (3) having a hydroxyl number of from 10 to less than 150 mg KOH/g and an average nominal hydroxyl functionality of from 2 to 6 and water, wherein the amount of polyisocyanate (1), polyol (2), polyol (3) and water is 55-80, 3-20, 10-30 and 2-6 parts by weight respectively per 100 parts by weight of polyisocyanate (1), polyol (2), polyol (3) and water, in the presence of a catalyst and a fire retardant and wherein the reaction is conducted at an isocyanate index of 70-150 and wherein the polyisocyanate is reacted with one or more isocyanate-reactive compositions comprising one or more of the aforementioned polyol (2), polyol (3) and water (not comprising compounds which have a primary, secondary or tertiary nitrogen atom, with the exception of a catalyst 2 and/or the protic acid of this catalyst 2, which catalyst 2 is discussed hereinafter and with the exception of part of the fire retardant which is also discussed hereinafter). This preferred process gives foams with reduced thermal degradation, especially when such foams are made as large buns e.g. on a moving conveyor belt (slab-stock foam), the foams have improved stability and a low amount of extractables.
[0027] An even further preferred process is a process for preparing a rigid foam by reacting a polyisocyanate (1), a polyether polyl (2) having an average equivalent weight of 70-300 and preferably of 70-150, having an average nominal hydroxyl functionality of from 2 to 6 and preferably from 2 to 3 and an oxyethylene content of at least 75% by weight, a polyether polyl (3) having an average equivalent weight of 1000-3000, having an average nominal hydroxyl functionality of 2 to 3 and preferably of 2 and having the structure

\[ \text{HO-}(\text{EO})_x-\text{(PO})_y-\text{(EO})_z-\text{Y}[\text{O-}(\text{EO})_y-\text{(PO})_z-\text{(EO})_x\text{H}]_n \] \quad \text{Formula 1}

wherein EO is an ethylene oxide radical, PO is a propylene oxide radical, x=1-15 and preferably 3-10, y=0-6 and preferably 1-4, z is such so as to arrive at the above equivalent weight, n = 1-2 and X is a hydrocarbon radical having 2-10 and preferably 2-6 carbon atoms or a radical having the formula \( -\text{CH}_2-\text{CH}_2-(\text{OCH}_2-\text{CH}_2)_1-2^- \), and water in the presence of a catalyst and a fire retardant wherein the amount of polyisocyanate (1), polyl (2), polyl (3) and water is 55-80, 3-20, 10-30 and 2-6 parts by weight respectively per 100 parts by weight of polyisocyanate (1), polyl (2), polyl (3) and water and wherein the reaction is conducted at an isocyanate index of 70-150 and wherein the polyisocyanate is reacted with one or more isocyanate-reactive compositions comprising one or more of the aforementioned polyl (2), polyl (3) and water (and not comprising compounds which have a primary, secondary or tertiary nitrogen atom, with the exception of catalyst 2, its protic acid and part of the fire retardant). Preferably the amount of water is 3-5 parts by weight calculated on the same basis as above. Preferably the weight ratio of water and polyl (3) is 0.1 to 0.4:1 and the weight ratio of polyl (3) and of polyl (2) + water is 0.9-2.5:1.

[0028] Most preferred polyether polyols (3) are those according to formula 1, described hereinbefore. Those having a nominal hydroxyl functionality of 3 may be prepared by ethoxylation of an initiator, followed by propoxylation and again ethoxylation, wherein the initiator is a triol like glycerol and/or trimethylol propane. Those having a nominal hydroxyl functionality of 2 may be prepared by ethoxylation of ethylene glycol, diethylene glycol and/or triethylene glycol, followed by propoxylation and again ethoxylation; or by propoxylation of ethylene glycol, diethylene glycol and/or triethylene glycol followed by ethoxylation; or by propoxylation of a polyoxyethylene polyl having 4-15 oxyethylene groups followed by ethoxylation. Mixtures of such most preferred polyols may be used as well. Although not necessary other polyols may be used together with these most preferred polyols according to formula 1, provided the amount does not exceed 30% by weight based on the weight of these polyols according to formula 1. Such polyols according to formula 1 are commercially available (e.g. Daltocel F 430 from Huntsman Polyurethanes, Daltocel is a trademark of Huntsman ICI Chemicals LLC).

[0029] As catalyst those may be used which enhance the formation of urethane and urea bonds like amines, such as triethylene diamine, tin compounds, such as dibutyltin dilaurate and stannous octoate, and/or phosphates like NaH2 PO4 and Na2 HPO4. Amine catalysts preferably are avoided, with the exception of catalyst 2, see below. Preferably the following combination of catalysts is used: a tin salt of a carboxylic acid having 2-18 carbon atoms (hereinafter called "catalyst 1"), together with a lithium, sodium, potassium, rubidium, cesium, magnesium, calcium, strontium and/or barium salt of a protic acid, the acid having at least 2 acidic hydrogen atoms and having a pKa in water of 2-10, and water in the presence of a catalyst and a fire retardant wherein the amount of polyisocyanate (1), polyl (2), polyl (3) and water is 55-80, 3-20, 10-30 and 2-6 parts by weight respectively per 100 parts by weight of polyisocyanate (1), polyl (2), polyl (3) and water (and not comprising compounds which have a primary, secondary or tertiary nitrogen atom, with the exception of catalyst 2, its protic acid and part of the fire retardant). Preferably the amount of water is 3-5 parts by weight calculated on the same basis as above. Preferably the weight ratio of water and polyl (3) is 0.1 to 0.4:1 and the weight ratio of polyl (3) and of polyl (2) + water is 0.9-2.5:1.

[0030] For simplicity reasons the above salts of the protic acids are called 'catalyst 2'; it is to be noted however that these compounds in fact have a deactivating effect upon catalyst 1. Without wishing to be bound by any theory it is believed that catalyst 2 suppresses the formation of certain intermediate tin compounds during the preparation of the foam, which intermediate tin compounds would enhance certain undesirable hydrolytic processes which lead to said degradation.

The weight ratio of catalysts 1 and 2 as used in this process may range preferably from 50:50 to 90:10.

[0031] The carboxylic acid in catalyst 1 may be selected from saturated or unsaturated aliphatic, cycloaliphatic and araliphatic hydrocarbons and from aromatic hydrocarbons having one carboxylic acid groups. Preferably they have 2-18 carbon atoms. Most preferred monocarboxylic acids are the saturated aliphatic carboxylic acids having 2-12 carbon atoms, like acetic acid, propionic acid, n-butyric acid, isobutyric acid, n-valeric acid, caproic acid, heptanoic acid, octanoic acid, nonanoic acid, decanoic acid, undecanoic acid and dodecanoic acid. Examples of tin catalysts of this type are dibutyltin dilaurate and stannous octoate.

[0032] The protic acid of catalyst 2 may be selected from a wide range of compounds. Preferably such compounds are selected from those containing at least 2 groups selected from -COOH and aromatic thiol.

Preferably the number of acidic hydrogen atoms is at least 3. Different metal salts may be used in combination. Further metal salts may be used wherein all or only a part of the acidic hydrogens has been replaced by the metal ion. Preferably 10-90% of the acidic hydrogen atoms has been replaced with the metal ion; when the acid is used instead of its salt more tin catalyst is required in order to obtain the same gel time and when all acidic hydrogen atoms have been replaced
Preferably catalyst 2 has a solubility in water of at least 5 gram of catalyst 2 per liter water at 25°C. Examples of useful catalysts are the Li, Na, K, Rb, Cs, Mg, Ca, Sr and/or Ba salts of: citric acid, 1,2,4,5 benzenetetracarboxylic acid (BCTA), ethylenediaminetetraacetic acid (EDTA), ethylenebis-(oxyethylene)+nitro)tetraacetic acid (EGTA), N-(2-hydroxyethyl)- ethylenediaminetriacetic acid (HEDTA), 1,3-diamino-2-hydroxypropane-N,N,N',N'-tetraacetic acid (DHPTA), 2-merca-tobenzoic acid (MBA), 2,2'-thiodiglycolic acid (TDGA), poly(acrylic acid) (PAcA), poly(2-acylamido-2-methyl-1-propanesulfonic acid) (PAcAmMPSA), copolymers of acrylamide and acrylic acid (PAc-Am-co-PAcA), of acrylic acid and maleic acid (PACa-co-PAcA), of vinylpyrrolidone and acrylic acid (PVP-co-PAcA), said polymers and copolymers having average molecular weights between 500 and 1000000, preferably between 1000 and 500000.

The amount of catalyst 1 and catalyst 2 preferably varies from 0.2 to 3% by weight calculated on the weight of all ingredients used to prepare the polyurethane foam.

Catalysts 1 and 2 are preferably mixed with the isocyanate-reactive compounds before the foaming reaction takes place. More preferably catalyst 1 is mixed with a part of the isocyanate-reactive compounds and catalyst 2 is mixed with another part of the isocyanate-reactive compounds; subsequently these mixtures are fed to a mixing head of a foaming device where they are mixed with the polyisocyanate.

In addition to the polyisocyanate, the isocyanate-reactive compounds and the blowing agent, one or more auxiliaries or additives known per se for the production of polyurethane foams may be used. Such optional auxiliaries or additives include foam-stabilizing agents or surfactants, for example siloxane-oxalkylene copolymers and polyoxyethylene polyoxypropylene block copolymers, anti-oxidants, anti-static agents, IUV stabilisers, antimicrobial and anti-fungal compounds and fillers like latex, TPU, silicates, barium and calcium sulphates, chalk, glass fibers or beads and polyurethane waste material. Preferably additives and auxiliaries are used which do not comprise primary, secondary or tertiary nitrogen atoms.

In operating the process for making rigid foams according to the invention, the known one-shot, prepolymer or semi-prepolymer techniques may be used together with conventional mixing methods and the rigid foam may be produced in the form of slabstock, mouldings including foam in fabric and pour-in-place applications, sprayed foam, frothed foam or laminates with other materials such as hardboard, plasterboard, plastics, paper or metal or with other foam layers.

It is convenient in many applications to provide the components for polyurethane production in pre-blended formulations based on each of the primary polyisocyanate and isocyanate-reactive components. In particular, an isocyanate-reactive composition may be used which contains the catalysts and the auxiliaries, additives and the blowing agent in addition to the isocyanate-reactive compounds (2) and (3) in the form of a solution, an emulsion or dispersion.

The isocyanate-reactive components may also be supplied independently to the polyisocyanate as two or more compositions containing the catalysts and the additives and auxiliaries; in particular one composition comprising catalyst 2 and/or the prolic acid of catalyst 2, water and polyol (2) and another composition comprising polyol (3), catalyst 1 and antioxidant may be fed from different storage tanks into the mixing head of a device for making foam, in which mixing head they are mixed with the polyisocyanate. The relative amounts of catalyst 2 and/or the prolic acid of catalyst 2, water and polyol 2 are 0.1-20, 10-55 and 35-85 parts by weight respectively and preferably 0.1-10, 10-55 and 35-85 parts by weight respectively per 100 parts by weight of catalyst 2 and/or the prolic acid of catalyst 2, water and polyol 2. Such compositions are made by mixing the three ingredients.

As said before, catalyst 2 and/or the prolic acid of catalyst 2 preferably has a solubility in water of at least 5 gram of catalyst 2 per liter water at 25°C. When catalyst 2 and/or the prolic acid of catalyst 2 is used in the above composition it preferably has a solubility of at least 2g of catalyst 2 and/or the prolic acid of catalyst 2 per liter of polyol (2) and water irrespective of its solubility in water alone.

Most preferably catalyst 2 is used in these compositions and processes for making rigid polyurethane foams since it was found that the amount of tin catalyst, required to obtain a similar gel time, was higher when the prolic acid of catalyst 2 was used.

The rigid foam is prepared by allowing the aforementioned ingredients to react and foam until the foam does not rise any more.

After rise curing of the foam may be continued as long as desirable. In general a curing period of 1 minute to 24 hours and preferably of 5 minutes to 12 hours will be sufficient. If desired curing may be conducted at elevated temperature. Subsequently the foam may be crushed. It is however preferred to allow the rigid foam obtained to cool down to below 80°C, preferably below 50°C and most preferably to ambient temperature prior to crushing. The rigid foam (i.e. before crushing) preferably has a core density of 3-35 and more preferably of 8-25 kg/m3 (ISO 845).

The rigid foam (i.e. before crushing) prepared has a substantial amount of open cells. Preferably the cells of the rigid foam are predominantly open. The crushing may be conducted in any known manner and by any known means. The crushing may for instance be
conducted by applying mechanical force onto the foam by means of a flat or pre-shaped surface or by applying variations of external pressure.

[0044] In most cases a mechanical force sufficient to decrease the dimension of the foam in the direction of the crushing by 1-90%, preferably by 50-90% will be appropriate. If desired crushing may be repeated and/or carried out in different directions of the foam. Due to the crushing the ball rebound increases considerably in the direction of the crushing. Due to the crushing the density of the foam may increase. In most cases this increase will not exceed 30% of the density before crushing.

[0045] The foam may be crushed in the direction of foam rise. A special foam is obtained when the crushing is conducted in a direction perpendicular to the direction of foam rise: then a foam is obtained with a highly anisotropic cell structure.

[0046] Although it is difficult to give more precise directions for the crushing since it will inter alia depend on the density of the foam, the rigidity of the foam, the type of crushing device used, we believe those skilled in the art are sufficiently aware of the phenomenon of crushing of polyurethane foams that they will be able to determine the appropriate crushing manner and means with the above guidance, certainly in the light of the following examples.

[0047] By crushing the ball rebound is increased at least in the direction of crushing. The increase is at least 10%. The core density of the flexible foam is 3-30 and preferably 3-20 kg/m³.

[0048] After the crushing the foam may be subjected to a heat treatment in order to reduce the density increase caused by the crushing. This heat treatment is conducted at 70-200°C and preferably at 90-180°C for 0.5 minute to 8 hours and preferably for 1 minute to 4 hours.

After the crushing and optionally the heating a novel flexible foam is obtained which has exceptional properties. Despite the fact that the foam is flexible, it does not show a significant change of the Young's storage modulus E' over hours and preferably for 1 minute to 4 hours.

[0049] If the Tg h is not too high the foam might be used in thermoforming processes to prepare shaped articles. Preferably the Tg h of the foam is between 80 and 180°C, most preferably between 80°C and 160°C for such thermoforming applications. Further it was found that foams, which have been made by using a relatively low amount of the polyols having a low molecular weight, show a small or non-visible Tg h by DMTA (the modulus change at Tg h is small or the modulus changes gradually until the foam thermally decomposes); such foams may be used for thermoforming activities as well.

[0050] Further the foams show good load-bearing properties like compression hardness values without the use of external fillers together with a good resilience, tear strength and durability (fatigue resistance) even at very low densities. In conventional flexible foams often high amounts of filler need to be used to obtain satisfactory load-bearing properties. Such high amounts of fillers hamper the processing due to a viscosity increase.

[0051] The foams of the present invention may be used as cushioning material in furniture and automotive and aircraft seating and in mattresses, as carpet backing, as hydrophilic foam in diapers, as packaging foam, as foams for sound insulation in automotive applications and for vibration isolation in general. The foam according to the present invention further may be used together with other, conventional flexible foams to form composites, like e.g. in mouldings; such composites may also be made by allowing the ingredients for making the conventional flexible foam to form said foam in a mould in the presence of the foam according to the present invention or alternatively by allowing the ingredients for making the rigid foam according to the present invention to form said rigid foam in a mould in the presence of the conventional flexible foam followed by crushing the moulding so obtained. Further the foams according to the present invention may be used as textile cover, as cover for other type of sheets, as carpet underlay or felt-replacement; the so-called flame lamination technique may be applied to adhere the foam to the textile, the carpet or the other sheet. In this respect it is important to note that the foam according to the present invention is suitable to be cut in sheets of limited thickness, e.g. of about 1 cm and less. Still further the foam according to the present invention may be used as insulation material around pipes and containers.

[0052] The fire retardancy of foams which do not contain flame retardant is not sufficient to meet the test requirements for certain applications. For example, a foam which has not been combustion modified may typically have an LOI of
18.4 and an MVSS302 burn rate of more than 150mm/min. It is therefore desirable, and in certain applications necessary, to incorporate fire retardants into the foam formulation in order to enhance the fire performance. For example, an LOI of more than 20 is often desirable and an MVSS302 burn rate of less than 100mm/min is necessary for certain automotive applications.

[0053] The fire retardant used in the invention is a combination of 1) expandable graphite and 2) compounds of formula

\[
\begin{align*}
&O \\
&\mid \\
&X \quad P \quad Y \\
&\mid \\
&Z
\end{align*}
\]

wherein X, Y and Z are independently selected from the groups -R and -OR' wherein R is an alkyl, aryl or aralkyl group having 1-12 and preferably 1-10 carbon atoms, and R' is an aryl or aralkyl group having 6-12 and preferably 6-10 carbon atoms and wherein the phosphorous-containing compounds are selected from triphenylphosphine oxide, triphenylphosphine, triphenylphosphonate and compounds having one or more, and preferably one, alkyl group(s) having 1-6 carbon atoms, attached to one or more of the aromatic rings of these triphenylphosphine, - phosphonate and - phosphine oxide.

[0054] The expandable graphite is already known in the art.

[0055] The phosphorous-containing compounds include the commercially available Reofos 50 and Kronitec CDP both obtainable from FMC Corporation, which are isopropylated triphenyl phosphate and cresyldiphenyl phosphate, respectively.

[0056] Preferably, the relative amount of the compounds in such mixtures is such that the weight ratio of phosphorous-containing compound to expandable graphite is from about 1/9 to about 4/1.

[0057] The amount of fire retardants used to prepare the foam is preferably such that the combined weight of phosphorous-containing compound and expandable graphite is 5-30%, most preferably 6-20%, by weight calculated on the total formulation (polyisocyanate, polyols, water, catalyst, additives, auxiliaries and fire retardants).

[0058] The fire retardants may be fed to the mixing head of the device to make the foam separately or after having been mixed. According to one embodiment, the fire retardant system is premixed with the isocyanate-reactive composition or with the isocyanate composition. Such compositions also are part of the present invention. The amount of fire retardant(s) in the polyisocyanate composition is 5-40% by weight and preferably 8-30% by weight whereas the amount of fire retardant(s) in the isocyanate-reactive composition is 20-75% by weight, preferably 25-60% by weight calculated on the amount of composition and fire retardant. Preferably, the fire retardants are pre-mixed with the isocyanate-reactive composition.

[0059] Such compositions are prepared by combining the ingredients in any order under ambient conditions or, if desirable, at elevated temperature followed by normal or high shear mixing. Experiments have shown that the process conditions for preparing the rigid foams are relatively demanding. The fire retardants used in the present invention provide for reduced levels of or the avoidance of scorching; they showed to be sufficiently stable; they can be provided as liquids or as liquid dispersions which makes them easily processable in making the foams and they provide good fire retarding properties to the foams made.

[0060] Further the fire retardants mentioned before may be used together with other fire retardants and in particular together with melamine and /or guanidine carbonate. The amount of such other fire retardant is 0.5-20 % by weight and preferably 1-10 % by weight calculated on the total formulation.

[0061] Mixtures of fire-retardant systems of the invention and/or mixtures of expandable graphite and/or mixture of phosphorous-containing compound are also contemplated.

[0062] The use of the phosphorous-containing compound allows the reduction of the viscosity of a composition (either polyol or polyisocyanate) containing the expandable graphite. This composition having a lower viscosity (such as below 10 Pa.s, preferably below 1 Pa.s) allows an improved processability. Preferably, the phosphorous-containing compound allows the reduction of the viscosity of the polyol composition containing the expandable graphite.

[0063] The above fire-retardant system is halogen-free and thus avoids any problem traditionally associated with halogens, which problems are nowadays to be eliminated.

[0064] The invention is illustrated by the following examples.
A catalyst containing polyol blend, blend A, was prepared by mixing 22 pbw of 'DABCO' T9 (catalyst from AIR PRODUCTS, DABCO is a trade mark), 350 pbw of an EO/PO polyol having a nominal functionality of 2, diethylene glycol as initiator, an EO content of 20.2% by weight (all tipped) and an hydroxyl value of 30 mg KOH/g.

A water containing blend, blend B, was prepared by dissolving 36 pbw EDTA-3Na in 400 pbw water. Subsequently 755 pbw of polyethylene glycol having a molecular weight of 200 and 235 pbw of triethylene glycol were added to this solution under continuous stirring.

A stabiliser containing polyol blend, blend C, was prepared by mixing 28 pbw of 'IRGANOX' 1135, 1.1 pbw of 'IRGAFOS' TNPP (stabilisers from Ciba-Geigy, IRGANOX and IRGAFOS are trade marks), 500 pbw of an EO/PO polyol having a nominal functionality of 2, diethylene glycol as initiator, an EO content of 20.2% by weight (all tipped) and an hydroxyl value of 30 mg KOH/g.

A polyisocyanate mixture, blend D, was prepared by mixing 184.4 pbw of polymeric MDI having an NCO value of 30.7 % by weight and an isocyanate functionality of 2.7 and 159.6 pbw of a uretonimine modified MDI having an NCO value of 31 % by weight, an isocyanate functionality of 2.09, a uretonimine content of 17 % by weight and 2,4'-MDI content of 20 % by weight.

All the fire retardants, with the exception of the expandable graphite, were either mixed with the isocyanate mixture or mixed with one of the polyol streams prior to making a foam, or were added as a separate stream. The expandable graphite was added as a separate stream or with the polyol stream. The expandable graphite and phosphorous-containing compound are introduced together with the polyol in examples 10 and 11.

Adding expandable graphite to the polyol increases the viscosity of the polyol stream. When the expandable graphite level for example 9 was added to half of the required EO/PO polyol, the viscosity of the mixture was measured to be around 50 Pa.s (at 30°C). If the same expandable graphite level is added to all of the required EO/PO polyol, then the viscosity of the mixture was measured to be around 5 Pa.s.

If the expandable graphite and the phosphorous-containing compounds are combined and added to all of the required EO/PO polyol as in example 10, then the viscosity of the mixture was measured to be below around 1 Pa.s.

In the table below the actual weight amount of chemicals used to produce the foam are given. All foams were produced at an isocyanate index of 100, with the exception of examples 9, 10 and 11, which were produced at an isocyanate index of 104. The reactant streams are first added to a vessel for mixing and are then transferred to a mould. The mixing vessel is typically a 750ml paper cup, but a 51 bucket was used in examples 9, 10 and 11. The mould used was typically a 51 bucket, but a 0.5x0.5x0.25m open box was used in examples 9, 10 and 11. First blend B is brought into the mixing vessel. Subsequently blends C, A and D are added. The content of the cup is mixed for 13 seconds with a 'HEIDOLPH' mechanical mixer (HEIDOLPH is a trade mark) at a speed of 5000rpm. After mixing the reaction mixture was poured into the mould and allowed to react. The gel time amounted to 40 to 50 seconds and the rise time amounted to 70 to 90 seconds. After at least 15 minutes the foam was taken out of the bucket and allowed to cool to ambient temperature. A rigid polyurethane foam was obtained. Prior to fire testing the foam samples were crushed by one compression (70% CLD) at 100 mm/min in the rise direction, followed by 10 crushings (70% CLD of the height after the first compression) at a rate of 500 mm/min in the rise direction of the foam using an INSTRON (INSTRON is a trade mark) mechanical tester mounted with flat plates. After crushing a flexible foam was obtained which had no major glass-rubber transitions between - 100° C and + 25° C.

The foams were submitted to the US Safety Standard FMVSS 302 rate of flame spread test for motor vehicle interior components and the limiting oxygen test according to ASTM D2863/91.

The following fire retardants were tested and compared:

DE-71 from Great Lakes is pentabromodiphenyl oxide containing 71wt% Br
Reofos 50 from FMC Corp. is isopropylated triaryl phosphate containing 8.4wt% P
Callotek grades from Graphitwerk Kropfmuehlm AG are expandable graphite.

The LOI and MVSS burn rate test results for example 1 to 11 are given in the table below:

Claims

1. Process for preparing a rigid foam by reacting a polyisocyanate (1), an isocyanate-reactive compound (2), said compound (2) having an average equivalent weight of at most 374 and an average number of isocyanate-reactive hydrogen atoms of from 2 to 8, an isocyanate-reactive compound (3), said compound (3) having an average equivalent weight of more than 374 and an average number of isocyanate-reactive hydrogen atoms of from 2 to 6 and water in the presence of a catalyst and in the presence of a fire retardant wherein the fire retardant is a combination of 1) expandable graphite and 2) compounds of formula:

   \[ \text{O} \]

   \[ \text{X} \quad \text{P} \quad \text{Y} \]

   \[ \text{Z} \]

   wherein X, Y and Z are independently selected from the groups -R and -OR' wherein R is an alkyl, aryl or aralkyl group having 1-12 and preferably 1-10 carbon atoms, and R' is an aryl or aralkyl group having 6-12 and preferably 6-10 carbon atoms and wherein the phosphorous-containing compounds are selected from triphenylphosphine oxide, triphenylphosphate, triphenylphosphonate and compounds having one or more, and preferably one, alkyl group(s) having 1-6 carbon atoms, attached to one or more of the aromatic rings of these triphenylphosphate, -phosphonate and -phosphine oxide.

2. The process according to claim 1, wherein the weight ratio of phosphorous-containing compound to expandable graphite is from about 1/9 to about 4/1.

3. The process according to claim 1 or 2, wherein the combined weight of phosphorous-containing compound and expandable graphite is 5-30%, most preferably 6-20%, by weight calculated on the total formulation.

4. Process for preparing a flexible foam by crushing the rigid foam prepared according to the process according to any one of claims 1-3.

5. Isocyanate-reactive composition comprising an isocyanate-reactive compound (2), said compound (2) having an average equivalent weight of at most 374 and an average number of isocyanate-reactive hydrogen atoms of from 2 to 8, and an isocyanate-reactive compound (3), said compound (3) having an average equivalent weight of more than 374 and an average number of isocyanate-reactive hydrogen atoms of from 2 to 6, and a fire retardant wherein the fire retardant is a combination of 1) expandable graphite and 2) compounds of formula:

   \[ \text{O} \]

   \[ \text{X} \quad \text{P} \quad \text{Y} \]

   \[ \text{Z} \]

   wherein X, Y and Z are independently selected from the groups -R and -OR' wherein R is an alkyl, aryl or aralkyl group having 1-12 and preferably 1-10 carbon atoms, and R' is an aryl or aralkyl group having 6-12 and preferably 6-10 carbon atoms and wherein the phosphorous-containing compounds are selected from triphenylphosphine oxide, triphenylphosphate, triphenylphosphonate and compounds having one or more, and preferably one, alkyl group(s) having 1-6 carbon atoms, attached to one or more of the aromatic rings of these triphenylphosphate, -phosphonate and -phosphine oxide.
Patentansprüche

1. Verfahren zur Herstellung eines Hartschaumstoffes durch Umsetzen eines Polyisocyanats (1), einer Isocyanatreaktiven Verbindung (2), wobei die Verbindung (2) ein durchschnittliches Äquivalentgewicht von höchstens 374 und eine durchschnittliche Anzahl von 2 bis 8 Isocyanatreaktiven Wasserstoffatomen hat, einer Isocyanatreaktiven Verbindung (3), wobei die Verbindung (3) ein durchschnittliches Äquivalentgewicht von mehr als 374 und eine durchschnittliche Anzahl von 2 bis 6 Isocyanatreaktiven Wasserstoffatomen hat, und Wasser in Gegenwart eines Katalysators und in Gegenwart eines flammenhemmenden Mittels, wobei das flammenhemmende Mittel eine Kombination eines 1) expandierbaren Graphits und 2) einer Verbindung der Formel

\[
\begin{align*}
  &\text{O} \\
  &\text{||} \\
  &\text{X} \quad \text{P} \quad \text{Y} \\
  &\text{||} \\
  &\text{Z}
\end{align*}
\]

ist, wobei X, Y und Z unabhängig aus den Gruppen -R und -OR' ausgewählt werden, wobei R eine Alkyl-, Aryl- oder Aralkylgruppe mit 1-12 und bevorzugt 1-10 Kohlenstoffatomen ist, und R' eine Aryl- oder Aralkylgruppe mit 6-12 und bevorzugt 6-10 Kohlenstoffatomen ist und wobei die phosphorhaltigen Verbindungen aus Triphenylphosphinoxid, Triphenylphosphat, Triphenylphosphonat und Verbindungen mit einer oder mehreren, und bevorzugt einer, Alkylgruppe(n) mit 1-6 Kohlenstoffatomen, die an einen oder mehrere der aromatischen Ringe dieses Triphenylphosphats, -phosphonats und -phosphinoxids gebunden sind, ausgewählt werden.

2. Das Verfahren gemäß Anspruch 1, wobei das Gewichtsverhältnis der phosphorhaltigen Verbindung zum expandierbaren Graphit ungefähr 1/9 bis ungefähr 4/1 ist.

3. Das Verfahren gemäß Anspruch 1 oder 2, wobei das gemeinsame Gewicht der phosphorhaltigen Verbindung und des expandierbaren Graphits 5-30 Gew.-%, am bevorzugtesten 6-20 Gew.-%, berechnet auf die Gesamtformulierung, ist.

4. Verfahren zur Herstellung eines flexiblen Schaums durch Zerkleinern des gemäß des Verfahrens nach einem der Ansprüche 1-3 hergestellten Hartschaumstoffs.

5. Isocyanatreaktive Zusammensetzung, die eine Isocyanatreaktive Verbindung (2), wobei die Verbindung (2) ein durchschnittliches Äquivalentgewicht von höchstens 374 und eine durchschnittliche Anzahl von 2 bis 8 Isocyanatreaktiven Wasserstoffatomen hat, eine Isocyanatreaktive Verbindung (3), wobei die Verbindung (3) ein durchschnittliches Äquivalentgewicht von mehr als 374 und eine durchschnittliche Anzahl von 2 bis 6 Isocyanatreaktiven Wasserstoffatomen hat, und ein flammenhemmendes Mittel umfasst, wobei das flammenhemmende Mittel eine Kombination eines 1) expandierbaren Graphits und 2) einer Verbindung der Formel

\[
\begin{align*}
  &\text{O} \\
  &\text{||} \\
  &\text{X} \quad \text{P} \quad \text{Y} \\
  &\text{||} \\
  &\text{Z}
\end{align*}
\]

ist, wobei X, Y und Z unabhängig aus den Gruppen -R und -OR' ausgewählt werden, wobei R eine Alkyl-, Aryl- oder Aralkylgruppe mit 1-12 und bevorzugt 1-10 Kohlenstoffatomen ist, und R' eine Aryl- oder Aralkylgruppe mit 6-12 und bevorzugt 6-10 Kohlenstoffatomen ist und wobei die phosphorhaltigen Verbindungen aus Triphenylphosphinoxid, Triphenylphosphat, Triphenylphosphonat und Verbindungen mit einer oder mehreren, und bevorzugt einer, Alkylgruppe(n) mit 1-6 Kohlenstoffatomen, die an einen oder mehrere der aromatischen Ringe dieses Triphenylphosphats, -phosphonats und -phosphinoxids gebunden sind, ausgewählt werden.
hosphinoxid, Triphenylphosphat, Triphenylphosphonat und Verbindungen mit einer oder mehreren, und bevorzugt einer, Alkylgruppe(n) mit 1-6 Kohlenstoffatomen, die an einen oder mehrere der aromatischen Ringe dieses Triphenylphosphats, -phosphonats und -phosphinoxids gebunden sind, ausgewählt werden.

Revendications

1. Procédé pour la préparation d'une mousse rigide en faisant réagir un polyisocyanate (1), un composé (2) réactif avec les isocyanates, ledit composé (2) ayant un poids équivalent moyen d'au plus 374 et un nombre moyen d'atomes d'hydrogène réactifs avec les isocyanates de 2 à 8, un composé (3) réactif avec les isocyanates, ledit composé (3) ayant un poids équivalent moyen supérieur à 374 et un nombre moyen d'atomes d'hydrogène réactifs avec les isocyanates de 2 à 6 et de l'eau en présence d'un catalyseur et d'un retardateur de flamme, dans lequel le retardateur de flamme est une association (1) de graphite expansible et (2) de composés de formule :

\[
\begin{align*}
O \\
\| \\
X \overset{P}{\longrightarrow} Y \\
\| \\
Z
\end{align*}
\]

dans laquelle X, Y et Z sont choisis indépendamment entre des groupes -R et -OR' dans lesquels R représente une groupe alkyle, aryle ou aralkyle ayant 1 à 12 et de préférence à 1 à 10 atomes de carbone et R' représente un groupe aryle ou aralkyle ayant 6 à 12 et de préférence 6 à 10 atomes de carbone, et dans lequel les composés contenant du phosphore sont choisis entre l'oxyde de triphénylphosphine, le phosphate de triphényle, le phosphonate de triphényle et des composés ayant un ou plusieurs, et de préférence un, groupes alkyle ayant 1 à 6 atomes de carbone, fixés à un ou plusieurs des noyaux aromatiques de ces composés consistant en phosphate de triphényle, ou phosphonate de triphényle et oxyde de triphénylphosphine.

2. Procédé suivant la revendication 1, dans lequel le rapport pondéral du composé contenant du phosphore au graphite expansible est compris dans l'intervalle d'environ 1/9 à environ 4/1.

3. Procédé suivant la revendication 1 ou 2, dans lequel le poids total du composé contenant du phosphore et du graphite expansible est compris dans l'intervalle de 5 à 30 %, de préférence de 6 à 20 %, en poids, calculé sur la base de la formulation totale.

4. Procédé pour la préparation d'une mousse flexible en écrasant la mousse rigide préparée par le procédé suivant l'une quelconque des revendications 1 à 3.

5. Composition réactive avec les isocyanates, comprenant un composé (2) réactif avec les isocyanates, ledit composé (2) ayant un poids équivalent moyen d'au plus 374 et un nombre moyen d'atomes d'hydrogène réactifs avec les isocyanates de 2 à 8, et un composé (3) réactif avec les isocyanates, ledit composé (3) ayant un poids équivalent moyen supérieur à 374 et un nombre moyen d'atomes d'hydrogène réactifs avec les isocyanates de 2 à 6, et un retardateur de flamme, dans laquelle le retardateur de flamme est une association (1) de graphite expansible et (2) de composés de formule :

\[
\begin{align*}
O \\
\| \\
X \overset{P}{\longrightarrow} Y \\
\| \\
Z
\end{align*}
\]
dans laquelle X, Y et Z sont choisis indépendamment entre des groupes -R et -OR' dans lesquels R représente une groupe alkyle, aryle ou aralkyle ayant 1 à 12 et de préférence à 1 à 10 atomes de carbone, et R' représente un groupe aryle ou aralkyle ayant 6 à 12 et de préférence 6 à 10 atomes de carbone, et dans laquelle les composés contenant du phosphore sont choisis entre l'oxyde de triphénylphosphine, le phosphate de triphényle, le phosphonate de triphényle et des composés ayant un ou plusieurs, et de préférence un, groupes alkyle ayant 1 à 6 atomes de carbone, fixés à un ou plusieurs des noyaux aromatiques de ces composés consistant en phosphate de triphényle, phosphonate de triphényle et oxyde de triphénylphosphine.
