Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

[0001] This invention relates to catheters and catheter guidewire apparatus and methods for making same. More specifically, the present invention relates to a guidewire apparatus with improved torque and flexure characteristics.

2. State of the Art

[0002] Catheter guidewires have been used for many years to "lead" or "guide" catheters to target locations in animal and human anatomy. This is typically done via a body lumen, for example such as traversing Luminal spaces defined by the vasculature to the target location. The typical conventional guidewire is from about 135 centimeters to 195 centimeters in length, and is made from two primary components—a stainless steel core wire, and a platinum alloy coil spring. The core wire is tapered on the distal end to increase its flexibility. The coil spring is typically soldered to the core wire at a point where the inside diameter of the coil spring matches the outside diameter of the core wire. Platinum is selected for the coil spring because it provides radiopacity for better fluoroscopic or other radiologic imaging during navigation of the guidewire in the body, and it is biocompatible. The coil spring also provides softness for the tip of the guidewire to reduce the likelihood of unwanted puncture of a Luminal wall or the damaging of this and/or other anatomy.

[0003] As mentioned, navigation of a guidewire through the anatomy is usually achieved with the assistance of radiographic imaging. This is conventionally done by introducing contrast media into the body lumen being traversed and viewing the guidewire in the body lumen using X-ray fluoroscopy or other comparable methods. The guidewire is provided with a curved or otherwise tip that is curved or bent to a desired angle so as to deviate laterally a short distance. By rotation of the wire the tip can be made to deviate in a selected direction from an axis of the guidewire about which it rotates. The guidewire is inserted into a catheter so that the guidewire can be advanced so that its distal end protrudes out the distal end of the catheter, and also pulled back in a proximal direction so as to be retracted into the catheter. The catheter enables introduction of contrast media at the location of the distal tip to enable the visualization of a Luminal space being traversed by the catheter and guidewire. Visualization is by fluoroscopy, for example, or another device. The guidewire and catheter are introduced into a Luminal space, comprising for example a vessel or duct and advanced therethrough until the guidewire tip reaches a desired Luminal branch. The user then twists the proximal end of the guidewire so as to rotate and point the curved distal tip into the desired branch so that the device may be advanced further into the anatomy via the luminal branch. The catheter is advanced over the guidewire to follow, or track, the wire. This procedure is repeated as needed to guide the wire and overlying catheter to the desired target location. The catheter accordingly provides a means to introduce contrast media, and also provides additional support for the wire. Once the catheter has been advanced to the desired location, the guidewire may be withdrawn, depending upon the therapy to be performed. Oftentimes, such as in the case of balloon angioplasty, the guidewire is left in place during the procedure and can be used to exchange catheters.

[0004] As is known, a guidewire having a relatively low resistance to flexure yet relatively high torsional strength is most desirable. As the guidewire is advanced into the anatomy, internal resistance from the typically numerous turns, and surface contact, decreases the ability to advance the guidewire further within the Luminal space. This, in turn, may lead to a more difficult and prolonged procedure, or, more seriously, failure to access the desired anatomy and thus a failed procedure. A guidewire with high flexibility helps overcome the problems created by internal resistance. However, if the guidewire does not also have good torque characteristics (torsional stiffness), the user will not be able to twist the proximal end in order to rotate the distal tip of the guidewire as required.

[0005] Among the approaches suggested in the prior art for increasing the flexibility of the tip of a guidewire is that of cutting axially spaced grooves in and near the tip, with the depths of the grooves increasing toward the tip. See U.S. Patent No. 5,437,288 (closest prior art). Increasing the flexibility of a tubular member for use in catheter applications by making cuts therein is also known. The use of cuts to increase flexibility on one side only of a tubular guidewire is disclosed in U.S. Patent No. 5,411,483. However, these prior art approaches do not inform the art how to increase the flexibility of the guidewire without also significantly diminishing its torsional stiffness. The result can be a guidewire with a machined portion that is very flexible, but which also has very low torsional strength.

SUMMARY OF THE INVENTION

[0006] It has been recognized that it would be desirable to have a guidewire that is very flexible at its distal tip, yet which retains a relatively high degree of torsional stiffness for facilitating its use and manipulation.

[0007] A catheter guidewire apparatus in accordance with principles of the invention comprises a thin elongate body of material having an longitudinal axis, and which is formed so as to define at a distal portion a configuration comprising a plurality of integrally formed beams disposed along the length of the body. The integral beams extend axially and transversely of the body and are positioned and formed to give the guidewire flexibility while maintaining a relatively high degree of torsional stiffness. By manipulating the size, shape, spacing, and orientation of the beams, the torsional stiffness of the guidewire relative to its flexibility or beam stiffness can be selectively altered. In order to optimize the performance of the
guidewire transverse and axial beams adjacent one to another are configured so that the strain (deformation) in the adjacent axial and transverse beams as defined above is as nearly as possible equal in magnitude when the guidewire is subjected to torsional and bending forces resulting from twisting and bending of the apparatus. These beams comprise the portions of the wall of a tubular body, or the outer portions adjacent the outer surface of a solid body member, which remain after cuts are machined into the body.

[0009] In a more detailed aspect, the beams can be formed between cuts, by making cuts in pairs substantially opposite from one another and substantially parallel to each other. The spacing and depth of the cuts comprising the cut pairs being adapted to provide desired maximum flexibility while sacrificing minimal torsional strength.

[0008] Other features and advantages of the invention will be apparent from the following detailed description, taken in conjunction with the accompanying drawings, which illustrate, by way of example, the features of the invention.

**BRIEF DESCRIPTION OF THE DRAWINGS**

[0010] FIG. 1 is a side, fragmented, partially crosssectional, view of one embodiment of a catheter guidewire apparatus configured in accordance with the principles of the present invention;

FIG. 2 is a side, fragmented, view of a portion of a guidewire showing different types of cuts or etchings which may be utilized in a solid or tubular guidewire in accordance with principles of the present invention;

FIG. 3 is a side, fragmented, view of the tip of a guidewire with radiopaque coil or band wrapped thereabout, in accordance with principles of the present invention;

FIGS. 4 and 5 show side, fragmented views of two embodiments of guidewires formed with cuts, in accordance with principles of the present invention;

FIG. 6 is a side, fragmented view of a tapered guidewire formed with cuts, in accordance with principles of the present invention;

FIG. 7 is a side, fragmented view of a solid guidewire formed with a coiled tip, in accordance with principles of the present invention;

FIG. 8 is a graph of guidewire tensile strength compared to bending stiffness for a micromachined guidewire in accordance with principles of the present invention;

FIG. 9 is a graph of the ultimate torsional strength of a micromachined guidewire in accordance with principles of the present invention compared to its bending stiffness;

FIG. 10 is a graph of the torsional stiffness of a micromachined guidewire in accordance with principles of the present invention compared to its bending stiffness;

FIG. 11 is a graph showing the ratio of torsional stiffness to bending stiffness of a micromachined guidewire in accordance with principles of the present invention compared to its bending stiffness;

FIGS. 12a, 12b, and 12c show cross-sectional views of guidewires disposed within lumens of circular and elliptical catheters;

FIG. 12d shows the potential serpentine path of a guidewire through a catheter which tends to wedge the guidewire within the catheter;

FIG. 13 shows a perspective, partially fragmented, view of a guidewire in accordance with principles of the invention in another embodiment;

FIG. 14 shows a side view, partially fragmented, of a core wire of the guidewire of FIG. 13 illustrating the grind profile;

FIG. 15 shows a side view, partially fragmented, of a core wire of the guidewire of FIG. 13 with a medial stainless steel wire coil added;

FIG. 16 shows a side view, partially fragmented, of a core wire of the guidewire of FIG. 13 with a medial wire coil and distal marker coil added;

FIG. 17 shows a side view, partially fragmented, of a core wire of the guidewire of FIG. 13 with a medial wire coil and distal marker coil and proximal stainless coil added;

FIG. 18 shows a side view, partially fragmented, of a core wire of the guidewire of FIG. 13 with a medial wire coil, distal marker coil, proximal stainless coil and micromachined tubing added at a distal tip portion;

FIG. 19 shows a fragmentary perspective view of a portion of a micromachined tubing segment such as shown in FIG. 18, in accordance with principles of the invention;

FIG. 20 shows a crosssectional view, taken along line 20-20 in FIG. 19 of the micromachined tube shown in FIG. 19;

FIG. 21 shows a fragmentary perspective view of a portion of a micromachined tubing segment such as shown in FIG. 19 subjected to torsional forces, illustrating deformation of the tubing;

FIG. 22 shows a cut orientation distribution progressing in an axial direction along a micromachined guidewire segment;

FIG. 23 shows a fragmentary side view of a portion of a micromachined tubing segment illustrating a cut orientation distribution; and

FIG. 24 shows a diagram further illustrating the cut set distribution shown in FIG. 23.

**DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT(S)**

[0011] With reference to FIG. 1 of the drawings which
illustrates one embodiment of a solid guidewire 200 made in accordance with the present invention. The guidewire 200 includes a proximal end 204 a distal end 208, and a midportion 210 disposed therebetween, with the proximal end being mounted in a conventional pin vise type torquing chuck 212. The guidewire 200 is preferably constructed of nickel titanium alloy, and may range in size from about 0.2 mm (.008 inches) to about 2.25 mm (.090 inches) in diameter and from about 135 to 300 centimeters in length. The guidewire 200 could also be made of stainless steel. Four preferred diameter sizes are 0.2 mm (.008 inches), 0.35 mm (.014 inches), 0.4 mm (.016 inches) and 0.875 mm (.035 inches).

[0012] Cuts, slots, gaps or openings 216 and 220 are formed in the guidewire 200 along the length thereof, including the midportion 210, either by saw cutting (e.g., diamond grit embedded semiconductor dicing blade), etching (for example using the etching process described in U.S. Patent No. 5,106,455), laser cutting, or electron discharge machining. Cuts 216 are angled to allow for a longer cut and thus greater flexibility, whereas cuts 220 are generally perpendicular to the long dimension of the guidewire.

[0013] As will be discussed in more detail below, the cuts are specifically configured to form transverse beams within the body of the guidewire. This configuration allows the cuts and beams to interact to provide for lateral flexibility in the guidewire, while maintaining torsional stiffness. By controlling and varying the spacing, depth and type of cuts, the flexure profile and torsional stiffness of the guidewire may be selectively and relatively independently modified. Generally, the more closely spaced the cuts and the greater their depth, the more flexible will be the guidewire. However, modification of the exact shape, orientation, and spacing of the cuts will also allow selective modification or preservation of the torsional characteristics of the cross section independent of flexibility.

[0014] The distal end 208 of the guidewire 200 may be preshaped with a curve, as shown, to allow for directing the guidewire around curves and bends. To maintain flexibility in the distal end 208, cuts may also be provided on that end. Advantageously, the tip is rounded to minimize the chance of traumatic piercing of body tissue. Also formed on the distal end 208 is a radiopaque marker or band 224. The band 224 may be gold or platinum alloy (for X-ray fluoroscopy) or gadolinium or dysprosium, or compounds thereof (for MRI) and may be formed on the distal end 208 by deposition, wrapping or use of shape memory alloy (NiTi) effect to "lock" the band around the end.

[0015] FIG. 2 is a side, fragmented view of a guidewire 230, showing three alternative type cuts 234, 238 and 240. These type cuts provide a kind of built in flexure stop to prevent further flexure of the guidewire when the cut openings close to contact one another and prevent further flexure in that direction. Wedge shaped cuts 234 may be formed on opposite sides of the guidewire 230, with the greater width of the wedge being at the bottom of the cut. T-shaped cuts 238 may likewise be formed on opposite sides of the guidewire 230, with the cross piece of the T being at the bottom of the cut. Cuts 240 are generally circular as shown. It will be apparent that other cut shapes could also be provided to meet the needs of the user. The cuts 234, 238, and 240 are shown oppositely oriented, but it will be apparent that the cuts could also be formed at circumferentially-spaced locations about the guidewire, or a alternating locations such as shown and described in more detail with regard to, for example, FIG. 5.

[0016] All three types of cuts shown in FIG. 2 form an integral transverse beam section, shown in cross-hatch as areas 232, 236, and 242, respectively, between oppositely disposed cuts. This configuration provides at least two distinct benefits. First, it allows the beam section to be longer than the gap of the flexure stop. This allows the amount of strain in the beam prior to stop engagement to be controlled by varying the ratio of beam length to gap size, allowing more flexibility, i.e. less bending resistance.

[0017] However, the location and shape of the beam section 232, 236, or 242 also greatly influences the torsional characteristics of the guidewire 230. As is well known by those skilled in mechanics, torsional strength is primarily provided by the outer portion of the cross section of the guidewire. Thus, for illustration, a relatively thin-walled pipe will have nearly the same torsional strength as a solid bar of the same diameter because the central portion of the cross section of the solid bar contributes very little to torsional strength. Similarly, by comprising a transverse beam which crosses the entire cross-section of the guidewire 230, the beam sections 232, 236, or 242 include a significant amount of the outer portion of the cross section of the guidewire, and therefore transmit varying proportions of the torsional forces from one side to the other of the cuts 234, 238, and 240 depending on their shape.

[0018] For example, beam 232 is relatively long (measured in the direction of the long axis of the guidewire), but is relatively deep (measured transverse to the long axis) and will therefore transmit a relatively large amount of torsional force. Beam 236 is longer and thinner than beam 232, and will therefore transmit a smaller amount of torsional force across the cut 238. Of the examples given in FIG. 2, beam 240 is the shortest and strongest of all, and will probably transmit the greatest amount of torsional force. However, given the size and shape of cuts 240, this configuration may provide the greatest flexibility. Because the small flexure stop gaps of cuts 234, 238, and 240 may be varied in width without changing the depth or overall shape of the cut, the flexibility of the guidewire section may be selectively altered without affecting the size or strength of the torsion beam section. Thus, the flexibility and torsional strength of the guidewire may be selectively and relatively independently altered.

[0019] Advantageously, longitudinally adjacent pairs of cuts may be rotated about 90 degrees around the wire.
from one another to provide flexure laterally and vertically. However, the cuts may be located to provide preferential flexure in only one, two, three, etc. directions, if that is desired. Of course, the cuts could be randomly formed to allow bending (flex) equally, non-preferentially in all directions or planes. This could be achieved by circumferentially spacing the cuts.

**[0020]** FIG. 3 shows an alternative embodiment for applying a radiopaque marker to the distal end of a guidewire 244, shown in side, fragmented view. An annular trough or channel 248 is formed at the tip of the guidewire 244, and a radiopaque wire coil, preferably made of platinum alloy, is wound about the guidewire in the channel. The coil 252 could be welded or soldered to itself to hold it in place at the tip of the guidewire 244. If a gold or platinum band is used with a nickel titanium alloy guidewire, the guidewire could be cooled and deformed to allow the coil to be placed on the wire and then when the guidewire were returned to room temperature, the coil would be maintained in place on the guidewire without the need for welding or soldering or other joining mechanism, except for joining the coil to itself.

**[0021]** FIG. 4 is a side, fragmented view of a solid guidewire 260 formed with opposing cuts 264 spaced along a portion of the guidewire, and opposed cuts 266 rotated 90 degrees from opposed cuts 268. As with cuts 266, the rotated cuts 268 are preferably arranged in opposing pairs, with opposite cut corresponding to 268 not visible on the far side of the guidewire. Of course, the cuts could be formed to provide preferential bending (flex) in one plane, or could be positioned to allow bending in multiple planes. This could be achieved, for example, by rotating adjacent pairs of cuts by 45 degrees with respect to one another or some other selected angular amount. Also shaded in FIG. 4 are the transverse beam sections 262 between adjacent opposing cuts 264. It will be apparent that the pairs of rotated cuts 268 will also form transverse beams therebetween, except that these beams will be oriented at an angle of 90 degrees relative to the beam between cuts 266.

**[0022]** FIG. 5 is a side, fragmented view of a solid guidewire 270 formed with staggered or offset cuts 274 on opposite sides of the guidewire. A curved distal end 278 is also shown with a radiopaque marker band 280. As with the FIG. 4 embodiment, certain pairs of offset cuts could be rotated with respect to the other pairs, to thereby control direction of flexure. This configuration also presents particular advantages regarding torsional control. As is evident from FIG. 4, opposed cuts produce thin flexure beams 262 between the bottoms of each pair of opposed cuts. The dimensions and flexure properties of these beams are determined by the depth, separation and width of the cuts and so the flexibility of a guidewire with opposed cuts may be controlled by varying these parameters.

**[0023]** Offset cuts, as indicated in FIG. 5, produce much larger flexure beams 272 in the area between each pair of adjacent cuts. As will be expected, these large beams are able to transmit a relatively large amount of torsion. Depending on the depth of the cuts 274, this section will also comprise relatively thin flexure beams 276 between the base of each cut and the opposing side of the guidewire. While these beams 276 are relatively thin, they will nevertheless transmit a relatively large amount of torsion because they are located toward the outside of the cross section.

**[0024]** It will be apparent that the flexure properties of this guidewire are determined not only by the depth and width of the cuts (as with opposed cuts) but also by the offset (axial spacing) of the cuts. Consequently, the flexibility of a guidewire with offset cuts can be more accurately controlled by varying any or all of these parameters. Also, the flexibility could be varied simply by controlling the degree of the offset while keeping the depth and width of the cuts constant. More importantly, however, the torsional strength of the guidewire can be maintained because the beam sections which primarily resist torsional force are more fully preserved with offset cuts.

**[0025]** Offset cuts provide additional advantages because it is more practical to produce a consistent pattern of this type of cut than with opposed cuts. Very flexible sections with opposed cuts require very deep and/or wide cuts, and controlling either parameter may be problematic since very deep cuts could overly weaken the guidewire and very wide cuts may result in catching on and/or damaging tissue through which the guidewire is threaded. Very flexible beams using the offset cut pattern, on the other hand, may be produced without the need for either deep or wide cuts, but rather by simply varying the distance or separation of the offset cuts, and this may be done very accurately.

**[0026]** FIG. 6 is a side, fragmented view of a solid guidewire 284 having an enlarged proximal section 288, which provides more torqueability, and a narrowed distal section 292, covered by a hydrophilic polymer sleeve 294. For example, the enlarged section could be 0.35 mm (.014 inches) in diameter whereas the narrowed section could be 0.25 mm (.010 inches) in diameter. The distal end 296 of the guidewire 284 is formed with cuts as earlier described. Of course, cuts could also be provided at other locations in the narrowed section 292 or in the enlarged section 288, to increase flexibility, while maintaining high torsional stiffness.

**[0027]** FIG. 7 is a side, fragmented view of a solid guidewire 300 having a tapered distal end 304 about which is wrapped a coil 308 made, for example, of platinum alloy. Disposed at the tip of the distal end 304 of the guidewire and in the end of the coil 308 is a solder ball 312. Cuts 316 may also be formed in the guidewire 300 as discussed earlier. In addition to the use of cuts to control the flexure of a guidewire, nickel titanium alloy guidewires can be heat treated to vary the flexure characteristics. For example, selective annealing along the length of the wire can change stress/strain relationship of the material, and thus the flexure.
cussed above, the guidewires can be made "flow direct-
able" by providing highly flexible distal ends. "Flow di-
rectability" means that the distal end of the guidewire
tends to "flow" with the blood around curves and bends
in a vasculature passageway. To reduce resistance to
movement of a guidewire in a vasculature passageway,
the surface of the guidewire may be electropolished to
increase the smoothness thereof, and additionally, a lu-
bricous coating may be applied to the surface of the
guidewiresuch coatings might illustratively include sil-
icone based oil and/or polymer or hydrophilic polymers.
Alternatively, a lubricious sleeve made, for example, of
a hydrophilic polymer could also be provided for disposal
over the guidewire.

Figures 8-11 provide graphical evidence of the
improvement this invention provides over the prior art.
These graphs depict actual test results of catheter
guidewires formed according to this invention, showing
the strength of the inventor's catheter guidewires com-
pared to the prior art, and the relative preservation of
torsional strength relative to flexibility. As noted above,
the prior art does include catheter guidewires with cuts
or notches formed therein to increase flexibility of the
distal end of the catheter. However, these cuts are not
formed so as to simultaneously preserve the torsional
strength of the guidewire. With these prior art catheter
guidewires, the distal end becomes very flexible, but has
very poor torsion transmission characteristics. The result
is that the end of the guidewire flops around, but cannot
easily be turned or rotated within a catheter or vessel.

FIG. 8 is a graph of guidewire tensile strength
compared to bending stiffness for the micromachined
guidewire of the present invention. The individual
(square) data points represent tension test results for mi-
cromachined guidewires. The ultimate tensile strength
in pounds is indicated on the vertical axis, while the bending
stiffness in psi is given on the horizontal axis. As with FIG. 8,
the square data points represent actual test results of
micromachined catheter guidewires, and the solid line
represents the theoretical results for a catheter guidewire
of solid circular cross section. It will be apparent from this
graph that as the bending stiffness (or size) of the
guidewire decreases, the expected or theoretical torsion-
al strength also decreases. This is depicted by the solid
line. However, as the actual test results indicate, as the
size or bending strength of the micromachined guidewire
decreases, the torsional strength does not correspond-
ingly decrease as would be expected. Instead, as can be
seen from the divergence of the data points from the solid
line, the torsional strength of the guidewire decreases at
a much slower rate. This situation is depicted in a slightly
different way in FIG. 10, which provides a graph of the
bending stiffness of the micromachined guidewire of the
present invention compared to its torsional stiffness in
psi. Again, the actual results diverge from the expected
results for smaller and more flexible guidewires.

The importance of this situation is most clearly
evident from FIG. 11, which is a graph showing the ratio
of torsional stiffness to bending stiffness of the microma-
chined guidewire of the present invention compared to
its bending stiffness. In this graph the vertical axis rep-
resents a ratio of torsional stiffness to bending stiffness
(JG/El), with the result that the expected relationship of
torsional stiffness to torsional stiffness (the solid line) is
now a horizontal line. In FIG. 11, this line is set equal to
unity, in order to more graphically show the actual results
of the inventors' tests. As can be seen from these actual
test results, as the flexure strength decreased, the tor-
sional strength of the micromachined guidewires was
more than 30 times more than expected.

The condition indicated by FIG. 11 represents
some unexpected results. When the inventors first began
micromachining catheter guidewires, as with the prior art,
the goal was primarily to increase the flexibility. However,
as guidewire sizes decreased and/or flexibility increased,
the inventors noticed a corresponding (and expected)
decrease in torsional strength. This is a significant pro-
blem with catheter guidewires because guidewires with
low torsional strength cannot be manipulated as easily,
and are more likely to become wedged or jammed into
the catheter or vasculature of the patient. With a torsion-
ally weak guidewire, when the user twists the proximal
end, there is a significant delay in the transmission of the
torque to the distal end. Indeed, like axially twisting the
end of a weak coil spring, most of the torque is not trans-
mitt ed at all. Instead, the geometry of the guidewire is
likely to be deformed into a serpentine shape and wedge
into the side of the catheter or vasculature in which it is
located.

FIG. 12 shows cross-sectional views of
guidewires disposed within the lumen of circular and el-
lipical catheters. As will be apparent, when a circular
catheter is advanced into the vasculature of a patient and
navigates curves and other tortuous routes, the cross-
sectional shape of the catheter frequently tends to flatten
out in places into a more elliptical cross-section. When
a guidewire 400 is disposed in catheter 402 having a circular cross-section, it would have no preference as to its location within the cross section -- its position will present a state of physical equilibrium regardless of its location because all locations are the same. However, with an elliptical catheter 404, the guidewire 400 in a central location represents a state of unstable equilibrium, like a ball sitting on the top of another ball. The result is that the guidewire will naturally gravitate to a point of stable equilibrium 406, in the tight corner of the catheter lumen. In this condition, it can be seen that the area of contact between the guidewire and the catheter is much larger, resulting in large frictional forces which will hinder the easy movement of the guidewire within the catheter.

This condition will also tend to wedge the guidewire within the catheter simply by virtue of the serpentine shape. FIG. 13 shows the potential serpentine path of a torqued guidewire 420 through a catheter 422. By virtue of the deformation of the guidewire 420, when an axial driving force (denoted Fwire in FIG. 13) is applied to the guidewire 420, it will be converted into an axial force (denoted Faxial) and a perpendicularly oriented wedging force (denoted Wedging Force) which will tend to jam the guidewire within the catheter.

To prevent these problems, the inventors experimented with methods of providing cuts in catheter guidewires that would increase flexibility without reducing torsional strength as much. It was hoped that for a guidewire of a given flexibility, the torsional strength could be increased by 50% above the theoretical or predicted torsional strength. After trying many configurations, the inventors discovered that forming cuts in the guidewires so as to create beams with a particular location and configuration would allow flexibility to be increased without a correspondingly large decrease in torsional strength. The inventors were pleasantly surprised when testing the present invention to find that instead of a 50% increase of torsional strength, they had found a way to provide a more than 3000% increase in torsional strength. As a result, guidewires formed by the present method provide significantly greater torsional strength relative to their flexibility than the prior art.

With reference to FIG. 13 a guidewire 500 in accordance with principles of the invention comprises a proximal portion 502 extending from a proximal end 504 to a first transition portion 506 where the diameter of the guidewire changes. This proximal portion comprised a stainless steel core wire 501 configured as solid wire of circular cross section. The core wire in the proximal portion is covered with a low friction coating. For example PTFE is used to coat the proximal portion in the illustrated example. The proximal portion has a diameter as large as needed to transmit torque sufficient for the intended use of the guidewire. For coronary and some peripheral uses for example a diameter of about 14 thousandths of an inch is appropriate, and is used in the illustrated example.

At the first transition portion 506 the stainless steel wire is ground to a smaller diameter, transitioning over an axial length sufficient to provide a smooth transition. This is about 50 mm (2 inches) in one embodiment. Beginning at and distal of the first transition portion the guidewire 500 has a more complex configuration. A proximal coil 508 is disposed over the stainless core wire 501. The core wire continues to the distal end 510 of the guidewire, the proximal coil overlaying the core wire as will be further explained. The proximal coil is attached to the core wire at the first transition portion 506 by a proximal solder joint 512 at a point where the inner diameter of the coil matches the outer diameter of the core wire. The diameter of the core wire continues to decrease under the proximal coil, and beyond it in accordance with a grind profile that will be described.

At a distal end of the proximal coil 508 the guidewire 500 in an exterior aspect comprises a micro machined tubing 514 formed of a superelastic material such as NiTi alloy. This micromachined tubing is very important to functionality of the catheter guidewire, as it transmits torque to the distal end 510 of the guidewire but is very flexible. The micromachined tubing overlays additional structure as will be described below. The micromachined tubing is attached to the proximal coil 508 via other underlying structure, and the core wire 501 at a medial solder and glue joint 516. The location of this joint is important as it is the point where the torsional force “carrying capacity” of the core wire 501 is substantially equal to that of the micromachined tubing. A force path is therefore established which extends through the core wire from the proximal end 504 of the guidewire 500 to the medial solder and glue joint 516, then continues through the micromachined tubing 514 to the distal end 510 of the guidewire 500.

As can be appreciated, the view of FIG. 13 is fragmented, and not to scale. The outer diameter of the proximal coil 508 is substantially the same as the proximal portion 502 of the core wire. The outer diameter of the micromachined tubing 514 at the distal tip portion 511 of the guidewire 500 is also approximately the same, all being about 14 thousandths of an inch. In one embodiment the proximal coil is about 225 mm (11 inches) long and the distal tip portion comprising the micromachined tubing is about 50 mm (2 inches) long. The distal tip portion can be given a curved or other bent configuration is known in the art.

At the distal end 150 of the guidewire 500 the micromachined tubing, underlying structure (not shown), and the core wire 501 are attached at a distal solder and glue joint 518. The core wire has a very small diameter at the distal end, the grind profile reducing it to approximately 2 thousandths of an inch prior to reaching that point. The distal solder and glue joint comprises an adhesive 520 which is formed into a rounded configuration at the distal end of the guidewire to form an atrumatic tip.

Turning to FIGs. 14-18 the construction of an exemplary guidewire configuration will be described in more detail. With reference particularly to FIG. 14, the
core wire 501 alone is seen to advantage, with the grind profile appreciable. The corewire has a rounded configuration at the proximal end 504 of the wire, and the proximal portion 502 is as previously described, and is about 1625 mm (65 inches) in length in one exemplary embodiment. The grind profile extends about 350 mm (14 inches) further to the distal end 510 of the guidewire 500. In addition to the first transition portion 506, a second 522 and a third 524 transition portion are provided. Distal of the first transition, which as mentioned is about 50 mm (2 inches) in length in the exemplary embodiment, the core wire has a first reduced diameter portion 526 having a length of about 150 mm (6 inches) and a diameter of about seven and a half thousandths of an inch. The second transition portion is also about 2 inches in length, and the diameter further reduces from that of the first reduced diameter portion to about five and a half thousandths of an inch. This diameter is maintained for about 62 mm (two and a half inches), to form a second reduced diameter portion 528. At the third transition portion 524 the diameter further decreases to about two thousandths of an inch, which is maintained to the distal end 510 as mentioned, to form a third reduced diameter portion 530. This third transition portion is about 2.5 mm (one tenth of an inch in length), and the third reduced diameter portion is about 2.5 and 22.5 mm (one and nine tenths inches) in length in the illustrated exemplary embodiment. The third reduced diameter portion is configured to be extremely flexible as will be appreciated, but retain sufficient axial strength to help prevent distal tip separation on withdrawal of the guidewire from a position where the tip may be stuck in the anatomy, and to assist in facilitating pushability of the distal tip portion 511 of the guidewire.

[0044] With reference to FIG. 15, the underlying structure mentioned before will now be described. A medial coil 532 is attached to the core wire 501 at the third transition portion 524. The medial coil has an outer diameter substantially equal to the inner diameter of the proximal coil 508 and the inner diameter of the micromachined tubing 514. It is attached by soldering, and this location of attachment on the third transition portion is that of the medial solder and glue joint mentioned above. Also, it will be noted that the location is near the proximal end of the third transition portion, so that the diameter of the core wire at this location is substantially the same as the second reduced diameter portion 528. As the core wire transfers torque to the micromachined tubing at this location as mentioned above, the location on the grind profile is important as it represents the "end of the line" for torque transmission through the core wire, and the diameter of the corewire is directly proportional to the amount of torsional force that can be transmitted, the location and diameter are chosen in conjunction with selection of the parameters of the micromachined tubing so that the "carrying capacity" for torque is substantially equal. A mis-match represents an inefficiency in this regard and is to be avoided unless for some design objective a discontinuity in torquability is desired at this point.

[0045] The medial coil 532 is formed of stainless steel in one embodiment, and has a proximal unwound portion 534 at its proximal end, to aid in more secure bonding to the core wire 501 as a longer length of coil wire can be bonded due to slight deformation thereby allowed to follow the grind profile. The medial coil has a distal unwound portion 536 which will be further described next.

[0046] Turning to FIG. 16, a distal coil 538 is disposed over the third reduced diameter portion at the distal tip portion. The proximal end of the distal coil is provided with an unwound portion 540 which cooperates with the distal unwound portion 536 of the medial coil to form a secure interlock by intertwining of the coils, then soldering. As will be appreciated the distal coil can be of slightly larger diameter wire, due to the reduced grind profile it overlays, but the outside diameter is held to be slightly less than that of the inside diameter of the micromachined tubing (not shown) as will be described. The distal coil is formed of a radiopaque material in the illustrated embodiment to provide enhanced fluoroscopic visibility. Materials such as platinum, gold, palladium, dysprosium, as known in the art, are used for this purpose, and accordingly the increased diameter wire used provides more radiopacity when formed of such a material useful for this purpose. The distal coil thus acts as a marker to aid in navigation of the guidewire within the anatomy of a patient. As will be appreciated, the drawing figures are not to scale, and the distal coil can be considerably longer than the medial coil 532. The distal end of the distal coil is soldered to the core wire 501 adjacent the distal end 510 at the location of the distal solder and glue joint 518.

[0047] With reference to FIGs. 14, 15, 16, and 17, it will be appreciated that the guidewire 500 apparatus is assembled by attaching the medial spring 532 to the core wire, then attaching the distal (marker) coil 538 to the medial coil, then the proximal coil is slipped over the assembly and soldered to the core wire 501 at the proximal solder joint 512 and to the medial coil 532 at the location of the medial solder and glue joint 516. The solder used throughout is a silver or gold alloy solder or another material regulatory-approved for such use.

[0048] With reference to FIG. 18, fabrication of the catheter is completed by placement of the micromachined tubing 514 over the distal tip portion 511. It is fixed in place by securing it at its proximal end at the medial solder and glue joint 516 by means of a suitable adhesive such as a UV cured regulatory-approved adhesive such as Dymax, and by attaching the distal end to the distal tip of the core wire 501, and also to the distal (marker) coil by an identical or similar adhesive. As mentioned this adhesive when cured forms a rounded tip 520 to reduce trauma, and completes the distal solder and glue joint which holds together the core wire, distal marker coil, and the micromachined tubing at the distal end 510 of the guidewire.

[0049] The guidewire can further include a micromachined "barcode" identification 142 located at a conven-
ient location such as adjacent the proximal or distal end of the guidewire. The barcode is made by very lightly scoring the surface to form a binary code to encode identifying information regarding the catheter. This is done by a similar process to that used to micromachine the tubing 514 or another guidewire as discussed above and as follows. The advantage of such a marking system is that individual guidewires can be identified, enabling "lot of one" custom manufacturing and marking of one to as many as desired guidewires 500.

[0050] Turning now to FIG. 19, discussion of the micromachined tubing 514 more specifically should include mention of how the tubing is made. In addition to the description above with regard to wires generally, and below with regard to this tubing segment specifically, further details regarding fabrication of the tubing can be found in copending U.S. patent application serial no., Attorney Docket No. T3681CIP1, the disclosure of which is hereby incorporated herein by reference.

[0051] As will be appreciated, enhanced performance is obtained by optimization of one or more physical attributes of the guidewire. In the case of the illustrated exemplary embodiment now being discussed, a unique construction combined with optimization provides increased torqueability while allowing flexure, so as to be compliant with tortuous vasculature in accessing a target site within the patient’s anatomy.

[0052] For the moment digressing to review of a more general case, when a member of circular cross section is used to transmit a torsional force, the overwhelming majority of the force is "transmitted" by the outer portions of the member, the capacity to resist deformation due to induced stress being maximum at the outer circumferential surface of the member. Accordingly, whether a tubular member or a solid member of circular cross-section of a given material is used to transmit torque, relatively little increase in diameter for the tubular member is required to transmit the same amount of torque because in fact the "middle" portion of a solid circular member contributes very little to resistance of the stresses, and hence does little to transmit them.

[0053] The present invention is directed to maximizing torque transmission, while minimizing resistance to bending of a guidewire body, for example in the tubular member 514 shown. To do so, from the foregoing it will be apparent that only the equivalent of a tubular structure is implicated, even though a solid member may be used. Therefore the following discussion will apply to solid wires as well, though it will be understood that this is because an assumption is made that the inner portion of the wire is not contributing appreciably, and the structure other than a tubular portion of it is being ignored. In practice a tubular configuration is advantageous as other structure can be placed inside, as in the case of the illustrated embodiment given by example herein employing a tubular micromachined tubing segment 514 at a distal tip portion 511.

[0054] One way in which the guidewire distal tip portion is optimized is using superelastic material, preferably formed as a tube, micromachining the tube to create a structure which maximizes torque transmission while minimizing resistance to bending. A section of micromachined tubing 514, having slot-like cuts formed therein is shown to illustrate the structure. The cuts are opposed in the illustrated embodiment. That is, two cuts are made from opposite sides of the tubing at the same location along the longitudinal axis of the tubing. The depth of the cuts is controlled to leave a segment 546 of the tubing wall extant between the cuts on each of the opposite sides (180 degrees apart) of the tubing. These segments will acts as "beams" as discussed above to carry forces across the cut area at that location along the longitudinal axis 548 of the tubing. As a matter of convention such segments will be referred to as "axial beams" 546 as they carry or transfer forces in roughly an axial direction from adjacent structure on one side to adjacent structure on an opposite side. When a pair of opposed cuts 550 is made adjacent to the cuts previously described (544) the location of the cuts is made such that the axial beam(s) 546A formed by the second set of cuts is displaced circumferentially from the adjacent axial beam(s) 546. This of course is done by rotation of the tube relative to the saw used to cut the tubing through some angle before cutting. This can be seen in FIG. 20. The amount of rotation is selected with each successive cut to give a pattern calculated to facilitate torque transmission while also facilitating bending of the tube after machining. The specifics of this cutting distribution will be discussed below. With reference again to FIG. 19, what is important to this discussion is that in addition to axial beams, other beams, which by convention we will call transverse beams 552 are created.

[0055] The transverse beams 552 are defined as the curved portion of the tubing wall between adjacent cuts 544, 550 and adjacent axial beams, e.g. 546 and 546A. As will be appreciated, these transverse beams carry forces from a particular set of axial beams to the two adjacent axial beams created by the adjacent set of cuts.

[0056] With reference to FIG. 21, as will be appreciated once a tube 514 has been fabricated and a torqueing force is applied at one end, say the proximal end, with respect to another, say the distal end, the forces in the machined tube will tend to deform the axial and transverse beams, e.g. 546 and 552. In order to optimize the machined tube for maximum torque transmission, the goal is to match, insofar as possible, the strain in the axial and transverse beams all along the length of the wire. This is so that one or the other will not constitute a weak point which will fail by deformation well beyond that of the adjacent axial or transverse beams when the torqueing force is applied. As can be appreciated, with reference to Fig. 19 this matching can be done in tubing of constant cross section by variation of several parameters, namely the location (spacing 555 between), width 556, and depth 558 of cuts (e.g. 544, 550) made. Wider spacing of cuts creates wider transverse beams, shallower cuts create wider axial
beams. Likewise more closely spaced cuts create narrower transverse beams, and deeper cuts create more narrow axial beams. Wider cuts create longer axial beams. The configuration of the micromachined tubing is defined by calculation, using well-known formulas for stress and stress/strain. The design process can further include finite-element analysis of the configuration to give localized stress and strain values. The calculations are repeated as necessary using incrementally changing parameters to optimize the design taking into account the concepts set forth herein.

[0057] As a practical matter in manufacturing, a saw blade of a specified width will be used. And accordingly the width of all cuts is held to this value. In the illustrated embodiment a diamond silicon wafer cutting saw blade (as is used in the microprocessor and memory chip manufacturing art— not shown) about one thousandth of an inch wide is used to make the cuts (e.g. 544). While it is possible to make wider cuts by making a first cut, then moving the wire relative to the blade by a distance up to a width of the blade, and repeating as necessary for wider cuts, speed of fabrication is higher if a single cut is used. Therefore, using this constant cut width, the possible variables are depth 558 of cut and spacing 555.

[0058] Given that cut width 556 is to be held constant, in one embodiment the other parameters are selected as follows. The bending stiffness desired at any selected location along a length of tubing is obtained by selection of an appropriate spacing 555 between cuts. Given that the width of cut is a constant, in the calculations, selection of a distance between the set of opposed cuts to be made (e.g. 546A) and the last set of opposed cuts made (e.g. 546) will define, by means of the calculations, the depth of the cuts to be made as the distance between cuts defines the width of the transverse beams, and the width of the transverse beams is related to the width of the axial beam by the condition of equality of strain values to be obtained for a given applied torsional force 554 as mentioned.

[0059] The locations of the axial beams 546 will be set by the relative angular displacement of the adjacent sets of opposed cuts, as will be described, and hence the width and the length of the transverse beams 552 will be known. The width of the axial beams to be created depends on the depth of cut. The length of each axial beam is the same and equal to the constant cut width (e.g. one thousandth of an inch in the illustrated embodiment). The depth of cut is determined by comparison of the strain in the each of the resulting axial beams (they are assumed to be the same, though in fact they may not be in all cases due to differing force distribution due to variations in geometry) and then matching the strain in the axial beam (s) (e.g. 546) with the strain in the transverse beam(s) (e.g. 552). As will be appreciated, four transverse beams are created between each set of opposed cuts. The resulting strains are evaluated in each of the four beams, but in one embodiment another simplifying assumption is made that the strain in the two shorter transverse beams is the same, and likewise the strain in the two longer transverse beams is the same. The greater of the resulting strains in the transverse beams is compared with the strain in the axial beams. This represents the force transmission path for transfer of the torque. The depth of cut 558 is varied until the strains are matched. This value is then used in making the cuts at that location.

[0060] Other factors are taken into consideration. For example, there is a practical limit on the size of axial and transverse beams. Too large at the desired advantages are lost, too small and imperfections in materials and variations within the tolerances in machining can compromise performance. This may be governed by the thickness of the tubing if tubing is used, the size of the saw blade, accuracy of the machining apparatus, etc. Generally speaking, axial or transverse beams having dimensions on a par with or smaller than the width of the cutting blade used to micromachine them are avoided.

[0061] The design process then, in summary, is in one embodiment to space the cuts (e.g. 544, 550) apart along the axis 548 of the tubing so as to provide bending as desired. The cuts will be closer together to give less resistance to bending, and more spaced apart to give more resistance to bending. (See, for example FIGs. 13 and 18, where the tubing segment 514 becomes more flexible toward the distal end 510 of the guidewire 500.) The stiffness can be controlled by means of partial variation of the spacing 555 of the cuts, the other parameters being selected as appropriate as described above. The bending stiffness of the tubing can vary along the longitudinal axis, for example being made to gradually become less stiff toward the distal end, by gradually decreasing the spacing between cuts as in the above example.

[0062] As discussed, the depth 558 of the cuts is calculated using stress/strain relationships to match the strain in the axial 546 and transverse 552 beams created. In one embodiment as the calculation progresses, the strain in the axial beams is matched to that of the greatest calculated in the previously calculated transverse beams. Alternatively another method could be employed, for example comparing the strain in a given axial beam 546A to that of the transverse beams 552, 552A on either side of the axial beam along the axis 548 of the tubing 514 to match the strain. In another embodiment the average of the highest strain values in transverse beams 552, 552A1, 552A2 (552A1 and 552A2 being of unequal length the strains may be markedly different), on either side can be used to match the strain in the axial beam 546A under consideration. As will be appreciated, varying the thickness of the axial beam(s) affects the forces transmitted to the transverse beams and therefore varies the stress and strain in the transverse beam; so, as a result, many iterations of these calculation steps can be required to optimize the design. Likewise, adjustment of the size of one set of axial and transverse beams will affect the stresses and strains in adjacent sets of axial and transverse beams, so additional calculations and re-calculations can be required to optimize by matching...
strain throughout all the adjacent axial and transverse beams. Practical considerations will require the use of a computer and appropriate algorithm programmed therein to optimize these design parameters.

[0063] With reference again to FIG. 20, the distribution of the orientation of adjacent cut pairs giving rise to the axial beams 546 left after the cuts are made, will now be discussed. The object is to provide a distribution of cut orientations along the length of the tubing that minimizes "preferred" bending directions of the micromachined tubing 514 giving rise to undesirable effects collectively referred to as "whip" or a deviation of expected rotational result at the distal tip of the guidewire from that expected by the user from rotational inputs made at the proximal end of the guidewire by turning the collet fixture 212.

[0064] With reference to FIG. 22, one way of organizing the cut distribution to minimize whip is to assume a first cut pair of opposed cuts (180 degrees apart) and a second pair of opposed cuts immediately adjacent will be offset by an angle of ninety degrees. Collectively the four cuts will be referred to as a first cut set 560. A second cut set 562 of adjacent opposed cuts oriented ninety degrees apart is subsequently made, these being oriented with respect to the first cut set (designated arbitrarily as oriented at 0 degrees) so as to be rotated 45 degrees. The next similar cut set 564 is oriented at 22.5 degrees, and the next at 67.5 degrees, and so on in accordance with the distribution graphically illustrated in the figure. The sequence repeats every 64 cut sets (128 opposed cuts, and 256 cuts in total).

[0065] With reference to FIGs. 23 and 24, the cut distribution is defined by a helical pattern. A first cut pair 570 is at zero degrees. A second cut pair 572 is rotated with respect to the first through a chosen angle "x". For example, this angle can be 85 degrees. A third cut pair 574 is oriented by rotation through an angle equal to 2x, or 170 degrees in the exemplary embodiment. This pattern is continued, as the next cut pair (not shown) is oriented at 3x or 255 degrees, etc. continuing to turn in the same direction and by the same magnitude of angular rotation, x. The bending axis 576 formed by the first cut pair 570 is oriented at 0 degrees; and the next bending axis 578 formed by the second cut pair is oriented at 85 degrees in the example, and the third bending axis 580 at 170 degrees, and so on. The pattern will repeat after 72 cut pairs (144 total cuts) in the illustrated example where x is equal to 85 degrees. The orientation of any pair of cuts (and hence the bending axis) will be given by the following sequence: Pair 1 = 0 degrees;
Pair 2 = x degrees; Pair 3 = 2x degrees; Pair N = (N-1)x degrees. Where the increment is 85 degrees this is equivalent to 0; 85; 170; 255; ...(N-1)85... degrees. This has been found to give good bending and torque transmission characteristics and low whip.

[0066] With reference now to FIGs. 9, 10, 11 and 13 in comparing 0.35 mm (.014 inch) diameter Ni Ti tubing micromachined as disclosed herein to conventional guidewire configurations and stainless steel tubing, it can be seen that the micromachined tubing is superior to conventional guidewire configurations when the diameter of the stainless steel core wire, which conventionally transmits the great majority of the torque, drops below about 0.125 mm (.005 inch) on the grind profile. Since no advantage is obtained when the core wire is this diameter and larger, there is no reason to provide micromachined tubing proximal of the point where the grind profile drops to this value. Accordingly, for example in the illustrated embodiment it will be observed that where the medial solder/glue joint (516 in the FIGs.) is located is substantially at the point where the grind profile drops to about 0.125 mm (.005 inch) diameter. As explained, the NiTi tubing segment which has been micromachined as described above provides a superior path for transmission of torque to the distal tip 510 of the guidewire from that point while at the same time facilitating bending. Thus the exemplary embodiment illustrates that the guidewire configuration can be optimized for cost as well, the less expensive stainless steel core wire and conventional coil configuration being provided up to the point where better characteristics are obtainable with a micromachined configuration.

[0067] Other features of the guidewire can include providing lubricious coatings on components distal of the proximal portion 502 previously described as including such a coating. For example a silicone coating as is known in the art can be applied in one of the many manners known in the art.

[0068] Another feature is that the micromachined tubing can be deburred after micro machining if necessary. For example an acid wash etching process can be used to deburr the inner surfaces, and the tubing can be placed on a mandrel and turned while being subjected to an abrasive jet to dauber and round the micromachined edges to minimize the possibility of catching on anatomy.

[0069] In another aspect, the micromachining pattern can be altered to provide preferred bending directions. This can be useful in customizing the guidewire to reach a target location within a particular anatomical structure, or even a particular individual patient. As an example of this, a MRI or CAT scan can produce a data set from which a preferred access route, for example vasculature to a target site, can be constructed in three dimensions. The guidewire can be micromachined to provide locally variable flexibility as needed to facilitate the traversing the last critical distance to the target site. A catheter individually customized for that patent could be made from that data set (for example sent to the manufacturer via the Internet) and shipped out to the user very rapidly, since micromachining is a computer-controlled automated process that could be customized based on the data set in accordance with another automated procedure. This guidewire (or catheter for that matter) could be individually identified by a bar code as described herein.

[0064] With reference to FIG. 22, one way of organizing the cut distribution to minimize whip is to assume a first cut pair of opposed cuts (180 degrees apart) and a second pair of opposed cuts immediately adjacent will be offset by an angle of ninety degrees. Collectively the four cuts will be referred to as a first cut set 560. A second cut set 562 of adjacent opposed cuts oriented ninety degrees apart is subsequently made, these being oriented with respect to the first cut set (designated arbitrarily as oriented at 0 degrees) so as to be rotated 45 degrees. The next similar cut set 564 is oriented at 22.5 degrees, and the next at 67.5 degrees, and so on in accordance with the distribution graphically illustrated in the figure. The sequence repeats every 64 cut sets (128 opposed cuts, and 256 cuts in total).

[0065] With reference to FIGs. 23 and 24, the cut distribution is defined by a helical pattern. A first cut pair 570 is at zero degrees. A second cut pair 572 is rotated with respect to the first through a chosen angle "x". For example, this angle can be 85 degrees. A third cut pair 574 is oriented by rotation through an angle equal to 2x, or 170 degrees in the exemplary embodiment. This pattern is continued, as the next cut pair (not shown) is oriented at 3x or 255 degrees, etc. continuing to turn in the same direction and by the same magnitude of angular rotation, x. The bending axis 576 formed by the first cut pair 570 is oriented at 0 degrees; and the next bending axis 578 formed by the second cut pair is oriented at 85 degrees in the example, and the third bending axis 580 at 170 degrees, and so on. The pattern will repeat after 72 cut pairs (144 total cuts) in the illustrated example where x is equal to 85 degrees. The orientation of any pair of cuts (and hence the bending axis) will be given by the following sequence: Pair 1 = 0 degrees;
Pair 2 = x degrees; Pair 3 = 2x degrees; Pair N = (N-1)x degrees. Where the increment is 85 degrees this is equivalent to 0; 85; 170; 255; ...(N-1)85... degrees. This has been found to give good bending and torque transmission characteristics and low whip.

[0066] With reference now to FIGs. 9, 10, 11 and 13 in comparing 0.35 mm (.014 inch) diameter Ni Ti tubing micromachined as disclosed herein to conventional guidewire configurations and stainless steel tubing, it can be seen that the micromachined tubing is superior to conventional guidewire configurations when the diameter of the stainless steel core wire, which conventionally transmits the great majority of the torque, drops below about 0.125 mm (.005 inch) on the grind profile. Since no advantage is obtained when the core wire is this diameter and larger, there is no reason to provide micromachined tubing proximal of the point where the grind profile drops to this value. Accordingly, for example in the illustrated embodiment it will be observed that where the medial solder/glue joint (516 in the FIGs.) is located is substantially at the point where the grind profile drops to about 0.125 mm (.005 inch) diameter. As explained, the NiTi tubing segment which has been micromachined as described above provides a superior path for transmission of torque to the distal tip 510 of the guidewire from that point while at the same time facilitating bending. Thus the exemplary embodiment illustrates that the guidewire configuration can be optimized for cost as well, the less expensive stainless steel core wire and conventional coil configuration being provided up to the point where better characteristics are obtainable with a micromachined configuration.

[0067] Other features of the guidewire can include providing lubricious coatings on components distal of the proximal portion 502 previously described as including such a coating. For example a silicone coating as is known in the art can be applied in one of the many manners known in the art.

[0068] Another feature is that the micromachined tubing can be deburred after micro machining if necessary. For example an acid wash etching process can be used to deburr the inner surfaces, and the tubing can be placed on a mandrel and turned while being subjected to an abrasive jet to dauber and round the micromachined edges to minimize the possibility of catching on anatomy.

[0069] In another aspect, the micromachining pattern can be altered to provide preferred bending directions. This can be useful in customizing the guidewire to reach a target location within a particular anatomical structure, or even a particular individual patient. As an example of this, a MRI or CAT scan can produce a data set from which a preferred access route, for example vasculature to a target site, can be constructed in three dimensions. The guidewire can be micromachined to provide locally variable flexibility as needed to facilitate the traversing the last critical distance to the target site. A catheter individually customized for that patent could be made from that data set (for example sent to the manufacturer via the Internet) and shipped out to the user very rapidly, since micromachining is a computer-controlled automated process that could be customized based on the data set in accordance with another automated procedure. This guidewire (or catheter for that matter) could be individually identified by a bar code as described herein.
Claims

1. An apparatus configured to be guided to a target location in anatomy, the apparatus comprising:

- a body (e.g., 200 or 514) having a proximal end (e.g., 204), a distal end (e.g., 208 or 510), and a longitudinal axis extending at least from the proximal end (e.g., 204) to the distal end (e.g., 208 or 510);
- a plurality of slots (e.g., 220, 234, 238, 240, 264, 266, 274, 316, 544, 550, 570, 572 or 574) formed into said body (e.g., 200 or 514); said slots (e.g., 220, 234, 238, 240, 264, 268, 274, 316, 544, 550, 570, 572 or 574) being substantially perpendicular to said longitudinal axis;
- said slots (e.g., 220, 234, 238, 240, 264, 268, 274, 316, 544, 550, 570, 572 or 574) substantially defining a plurality of segments (e.g., 232, 236, 242, 262, 272, 546, 546A, 546B, or 546C) of said body (e.g., 200 or 514);

characterised in

- said segments (e.g., 232, 236, 242, 262, 272, 546, 546A, 546B, or 546C) forming a substantially helical pattern at least part way along said axis; and said plurality of segments (e.g., 232, 236, 242, 262, 272, 546, 546A, 546B, or 546C) being substantially defining a plurality of segments (e.g., 232, 236, 242, 262, 272, 546, 546A, 546B, or 546C) of said body (e.g., 200 or 514);

2. The apparatus of claim 1:

- each said slot (e.g., 220, 234, 238, 240, 264, 266, 274, 316, 544, 550, 570, 572 or 574) being substantially parallel to at least two other said slots (e.g., 220, 234, 238, 240, 264, 268, 274, 316, 544, 550, 570, 572 or 574).

3. The apparatus of claim 1:

- each said slot (e.g., 220, 234, 238, 240, 264, 266, 274, 316, 544, 550, 570, 572 or 574) being substantially parallel to at least two other said slots (e.g., 220, 234, 238, 240, 264, 268, 274, 316, 544, 550, 570, 572 or 574).

4. The apparatus of claim 1, wherein alternating said segments (e.g., 232, 236, 242, 262, 272, 546, 546A, 546B, or 546C) along said axis form said substantially helical pattern.

5. The apparatus of claim 1:

- each said slot (e.g., 220, 234, 238, 240, 264, 266, 274, 316, 544, 550, 570, 572 or 574) being substantially in line with at least one other said slot (e.g., 220, 234, 238, 240, 264, 266, 316, 544, 550, 570, 572, or 574); and
- said segments (e.g., 232, 236, 242, 262, 546, 546A, 546B, or 546C) being between adjacent said substantially in-line slots (e.g., 220, 234, 238, 240, 264, 266, 316, 544, 550, 570, 572, or 574).

6. The apparatus of claim 5:

- each said slot (e.g., 220, 234, 238, 240, 264, 266, 274, 316, 544, 550, 570, 572, or 574) being substantially parallel to at least two other said slots (e.g., 220, 234, 238, 240, 264, 266, 274, 316, 544, 550, 570, 572, or 574); each said slot (e.g., 220, 234, 238, 240, 264, 266, 274, 316, 544, 550, 570, 572, or 574) having two endpoints and a midpoint; at least a plurality of said segments (e.g., 232, 236, 242, 262, 272, 546, 546A, 546B, or 546C) being between adjacent said substantially in-line slots (e.g., 220, 234, 238, 240, 264, 266, 316, 544, 550, 570, 572, or 574); and
- alternating said segments (e.g., 232, 236, 242, 262, 546, 546A, 546B, or 546C) along said axis forming said substantially helical pattern.

7. The apparatus of claim 1:

- said slots (e.g., 220, 234, 238, 240, 264, 266, 316, 544, 550, 570, 572, or 574) being arranged in a plurality of groups (e.g., 570, 572, or 574); each said slot (e.g., 220, 234, 238, 240, 264, 266, 316, 544, 550, 570, 572, or 574) being substantially perpendicular to said axis; and each said slot (e.g., 220, 234, 238, 240, 264, 266, 316, 544, 550, 570, 572, or 574) in a said group (e.g., 570, 572, or 574) being substantially equally spaced around said axis.

8. The apparatus of claim 7 each said slot (e.g., 220, 234, 238, 240, 264, 266, 316, 544, 550, 570, 572, or 574) in a said group (e.g., 570, 572, or 574) being located at substantially the same location along said axis.
9. The apparatus of claim 7 each said group (e.g., 570, 572, or 574) containing two slots (e.g., 220, 234, 238, 240, 264, 266, 268, 316, 544, 550, 570, 572, or 574).

10. The apparatus of claim 7, each longitudinally adjacent said group (e.g., 570, 572, or 574) being rotated around said axis from the previous said group (e.g., 570, 572, or 574) forming said helical pattern along said axis.

11. The apparatus of claim 10:

   each said slot (e.g., 220, 234, 238, 240, 264, 266, 268, 316, 544, 550, 570, 572, or 574) being substantially in line with at least one other said slot (e.g., 220, 234, 238, 240, 264, 266, 268, 316, 544, 550, 570, 572, or 574);
   said segments (e.g., 232, 236, 242, 262, 546, 546A, 546B, or 546C) being between adjacent said substantially in-line slots (e.g., 220, 234, 238, 240, 264, 266, 268, 316, 544, 550, 570, 572, or 574);
   each said slot (e.g., 220, 234, 238, 240, 264, 266, 268, 316, 544, 550, 570, 572, or 574), being substantially parallel to at least two other said slots (e.g., 220, 234, 238, 240, 264, 266, 268, 316, 544, 550, 570, 572, or 574);
   each said slot (e.g., 220, 234, 238, 240, 264, 266, 268, 316, 544, 550, 570, 572, or 574) having two endpoints and a midpoint;
   at least a plurality of said segments (e.g., 232, 236, 242, 262, 546, 546A, 546B, or 546C) being substantially between said midpoints of two axially adjacent said slots (e.g., 220, 234, 238, 240, 264, 266, 268, 316, 544, 550, 570, 572, or 574); and
   each said group (e.g., 570, 572, or 574) containing two slots (e.g., 220, 234, 238, 240, 264, 266, 316, 544, 550, 570, 572, or 574) in said group (e.g., 570, 572, or 574).

12. The apparatus of claim 10, said helical pattern repeating after approximately 72 said groups (e.g., 570, 572, or 574).

13. The apparatus of claim 10, said rotated around being by an angle slightly different than 180 degrees divided by the number of said slots (e.g., 220, 234, 238, 240, 264, 266, 268, 316, 544, 550, 570, 572, or 574) in said group (e.g., 570, 572, or 574).

14. The apparatus of claim 10, said number of said slots (e.g., 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572, or 574) in said group (e.g., 570, 572, or 574) being 2 and said angle being approximately 85 degrees.

15. The apparatus of claim 1 at least some of said slots (e.g., 234) having a wedge-shaped cross-sectional shape.

16. The apparatus of claim 1 at least some of said slots (e.g., 234) having a T-shaped cross-sectional shape.

17. The apparatus of claim 1 at least some of said slots (e.g., 234) having a substantially circular cross-sectional shape.

18. The apparatus of claim 1, said body (e.g., 200 or 514) being nitinol.

19. The apparatus of claim 1, said body (e.g., 514) being tubular.

20. The apparatus of claim 19 further including a wire disposed at least partially inside said body (e.g., 514).

21. The apparatus of claim 20, said wire being slidable inside said body (e.g., 514).

22. The apparatus of claim 19, the apparatus being a catheter.

23. The apparatus of claim 1 further comprising a tubular polymer sleeve coaxial with at least part of said body (e.g., 200 or 514).

24. The apparatus of claim 1, said slots (e.g., 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572, or 574) having rounded corners.

25. The apparatus of claim 1, said distal end (e.g., 208 or 510) comprising a substantially radiopaque marker (e.g., 252).

26. The apparatus of claim 1, the apparatus being a guidewire (e.g., 200, 300, 400, 420, or 500).

27. The apparatus of claim 26 further comprising a solid core wire (e.g., 501) attached to said body (e.g., 514).

28. The apparatus of claim 27, said body (e.g., 514) being tubular, at least part of said core wire (e.g., 501) being inside said body (e.g., 514).

29. The apparatus of claim 28 further comprising a coil (e.g., 508, 532, or 538), at least part of said core wire (e.g., 501) being inside said coil (e.g., 508, 532, or 538).
30. A method of constructing a device with a relatively low bending stiffness and a relatively high torsional stiffness for facilitating navigation through anatomy, the method comprising at least the steps of:

- providing a body (e.g., 200 or 514) having a proximal end (e.g., 204), a distal end (e.g., 208 or 510), and a longitudinal axis extending at least from the proximal end (e.g., 204) to the distal end (e.g., 208 or 510);
- cutting a group (e.g., 570, 572, or 574) of at least two slots (e.g., 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572, or 574), into the body (e.g., 200 or 514), each slot (e.g., 216, 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, or 550) being substantially perpendicular to the axis, each slot (e.g., 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, or 550) being substantially equally spaced around the axis;
- in any order, rotating the body (e.g., 200 or 514) around the axis by an angle, and advancing the body (e.g., 200 or 514) along the axis; and
- repeating said steps of cutting and in any order rotating and advancing, forming a helical pattern.

31. The method of claim 30, said cutting comprising grinding with a diamond abrasive blade.

32. The method of claim 30, the slots (e.g., 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572, or 574) said group (e.g., 570, 572, or 574) being located at substantially the same axial location.

33. The method of claim 30, the body (e.g., 514) being tubular.

34. The method of claim 30, at least a plurality of the groups (e.g., 570, 572, or 574) consisting of two slots (e.g., 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572, or 574) having a depth (e.g., 553) and a spacing (e.g., 555) between groups (e.g., 570, 572, or 574), the method further including selecting the depth (e.g., 553) and spacing (e.g., 555) to substantially equalize strain in the transverse beams (e.g., 552, 552A1, or 552A2) and axial beams (e.g., 546, 546A, 546B, or 546C).

Patentansprüche

1. Vorrichtung, die dafür konfiguriert ist, an einen Zielort in einer Anatomie geführt zu werden, wobei die Vorrichtung aufweist:

- einen Körper (z. B. 200 oder 514) mit einem proximalen Ende (z. B. 204), einem distalen Ende (z. B. 208 oder 510) und einer Längsachse, die sich mindestens vom proximalen Ende (z. B. 204) zum distalen Ende (z. B. 208 oder 510) erstreckt;
- eine Vielzahl von Schlitten (z. B. 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 oder 574), die in dem Körper (z. B. 200 oder 514) ausgebildet sind,
- wobei die Schlitten (z. B. 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 oder 574) im wesentlichen senkrecht zu der Längsachse sind und
- dadurch gekennzeichnet, daß die Segmente (z. B. 232, 236, 242, 262, 272, 546, 546A, 546B oder 546C) ein im wesentlichen helikales Muster zumindest teilweise entlang der Achse bilden; und

4. Vorrichtung nach Anspruch 1, wobei abwechselnde Segmente (z. B. 232, 236, 242, 262, 272, 546, 546A, 546B oder 546C) im wesentlichen helikale Muster bilden.

10. Vorrichtung nach Anspruch 7, wobei jede in Längsrichtung benachbarte Gruppe (z. B. 570, 572 oder 574) bezüglich der vorherigen Gruppe (z. B. 570, 572 oder 574) um die Achse gedreht ist, wobei das helikale Muster entlang der Achse entsteht.

12. Vorrichtung nach Anspruch 10, wobei das helikale Muster sich nach annähernd 72 Gruppen (z. B. 570, 572 oder 574) wiederholt.

(z. B. 570, 572 oder 574) zwei ist und der Winkel annähernd 85° ist.

15. Vorrichtung nach Anspruch 1, wobei mindestens einige der Schlitze (z. B. 234) eine keilförmige Querschnittsform haben.

16. Vorrichtung nach Anspruch 1, wobei mindestens einige der Schlitze (z. B. 238) eine T-förmige Querschnittsform haben.

17. Vorrichtung nach Anspruch 1, wobei mindestens einige der Schlitze (z. B. 240) eine im wesentlichen kreisförmige Querschnittsform haben.

18. Vorrichtung nach Anspruch 1, wobei der Körper (z. B. 200 oder 514) Nitinol ist.

19. Vorrichtung nach Anspruch 1, wobei der Körper (z. B. 514) röhrenförmig ist.

22. Vorrichtung nach Anspruch 19, wobei die Vorrichtung ein Katheter ist.

23. Vorrichtung nach Anspruch 1, ferner mit einer röhrenförmigen Polymerhülse, die mit mindestens einem Teil des Körpers (z. B. 200 oder 514) koaxial ist.

25. Vorrichtung nach Anspruch 1, wobei das distale Ende (z. B. 208 oder 510) einen im wesentlichen strahlenundurchlässigen Marker (z. B. 252) aufweist.

26. Vorrichtung nach Anspruch 1, wobei die Vorrichtung ein Führungsdraht (z. B. 200, 300, 400, 420 oder 500) ist.

27. Vorrichtung nach Anspruch 26, ferner mit einem massiven Kerndraht (z. B. 501), der an dem Körper (z. B. 514) befestigt ist.

30. Verfahren zur Herstellung einer Vorrichtung mit einer relativ geringen Biegesteifigkeit und einer relativ hohen Torsionssteifigkeit zur Erleichterung der Navigations durch eine Anatomie, wobei das Verfahren mindestens die Schritte aufweist:

  Bereitstellen eines Körpers (z. B. 200 oder 514) mit einem proximalen Ende (z. B. 204), einem distalen Ende (z. B. 208 oder 510) und einer Längsachse, die sich zumindest vom proximalen Ende (z. B. 204) zum distalen Ende (z. B. 208 oder 510) erstreckt;

  Wiederholen der Schritte des Abtragens und des in beliebiger Reihenfolge erfolgenden Drehens und Vorrückens, wobei ein helikales Muster entsteht.

33. Verfahren nach Anspruch 30, wobei der Körper (z. B. 514) röhrenförmig ist.

34. Verfahren nach Anspruch 30, wobei zumindest mehrere der Gruppen (z. B. 570, 572 oder 574) aus zwei Schlitzten (z. B. 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 oder 574) bestehen.

35. Verfahren nach Anspruch 34, wobei der Winkel etwa 85° ist.

36. Verfahren nach Anspruch 34, wobei die Schlitze (z. B. 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 oder 574) Querträger (z. B. 552, 552A1...
oder 552A2) und Axialträger (z. B. 546, 546A, 546B oder 546C) bilden, die Schlitze (z. B. 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 oder 574) eine Tiefe (z. B. 553) und eine Beabstandung (z. B. 555) zwischen Gruppen (z. B. 570, 572 oder 574) haben und das Verfahren ferner den Schritt aufweist: Wählen der Tiefe (z. B. 553) und Beabstandung (z. B. 555), um Spannung in den Querträgern (z. B. 552, 552A1 oder 552A2) und Axialträgern (z. B. 546, 546A, 546B oder 546C) im wesentlichen auszugleichen.

Reventications

1. Appareil qui est configuré pour être guidé jusqu'à un endroit cible dans une anatomie, l'appareil comprenant :

un corps (par exemple 200 ou 514) possédant une extrémité proximale (par exemple 204), une extrémité distale (par exemple 208 ou 510) et un axe longitudinal s’étendant au moins depuis l’extrémité proximale (par exemple 204) jusqu’à l’extrémité distale (par exemple 208 ou 510) ; plusieurs fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) formées dans ledit corps (par exemple 200 ou 514) ; lesdites fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) étant essentiellement perpendiculaires audit axe longitudinal ; lesdites fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) définissant essentiellement plusieurs segments (par exemple 232, 236, 242, 262, 272, 546, 546A, 546B ou 546C) dudit corps (par exemple 200 ou 514) ;

caractérisé en ce que

lesdits segments (par exemple 232, 236, 242, 262, 272, 546, 546A, 546B ou 546C) forment une configuration essentiellement hélicoïdale au moins sur une partie de la longueur dudit axe ; et

lesdites fentes (par exemple 220, 234, 236, 242, 262, 272, 546, 546A, 546B ou 546C) sont séparés, le long de ladite configuration essentiellement hélicoïdale, par lesdites fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574).

236, 242, 262, 272, 546, 546A, 546B ou 546C) le long dudit axe forment ladite configuration essentiellement hélicoïdale.

7. Appareil selon la revendication 1, dans lequel lesdites fentes (par exemple 220, 234, 238, 240, 264, 266, 274, 316, 544, 550, 570, 572 ou 574) sont arrêtées dans plusieurs groupes (par exemple 570, 572 ou 574) ; chacune desdites fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) est essentiellement perpendiculaire audit axe ; et chacune desdites fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) dans un desdits groupes (par exemple 570, 572 ou 574) est disposée en position essentiellement équidistante autour dudit axe.

8. Appareil selon la revendication 7, dans lequel chacune desdites fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) dans un desdits groupes (par exemple 570, 572 ou 574) est disposée essentiellement au même endroit le long dudit axe.

10. Appareil selon la revendication 7, dans lequel chacun desdits groupes (par exemple 570, 572 ou 574) adjacents dans la direction longitudinale a effectué une rotation autour dudit axe par rapport au précédent desdits groupes (par exemple 570, 572 ou 574) pour former ladite configuration hélicoïdale autour dudit axe.

12. Appareil selon la revendication 10, dans lequel ladite configuration hélicoïdale se répète après approximativement 72 desdits groupes (par exemple 570, 572 ou 574).

13. Appareil selon la revendication 10, dans lequel ladite rotation correspond à un angle qui est légèrement différent de 180° divisé par le nombre desdites fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) dans ledit groupe (par exemple 570, 572 ou 574).

14. Appareil selon la revendication 10, dans lequel ledit nombre desdites fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) dans ledit groupe (par exemple 570, 572 ou 574) est égal à 2 et ledit angle s’élève approximativement à 85°.

15. Appareil selon la revendication 1, dans lequel au moins un certain nombre desdites fentes (par exemple 234) possèdent une configuration cunéiforme en section transversale.

16. Appareil selon la revendication 1, dans lequel au moins un certain nombre desdites fentes (par exemple 238) possèdent une configuration en T en section transversale.

17. Appareil selon la revendication 1, dans lequel au moins un certain nombre desdites fentes (par exemple 240) possèdent une configuration circulaire en section transversale.
18. Appareil selon la revendication 1, dans lequel ledit corps (par exemple 200 ou 514) est du nitinol.

19. Appareil selon la revendication 1, dans lequel ledit corps (par exemple 514) est tubulaire.

20. Appareil selon la revendication 19, englobant en outre un fil métallique disposé au moins en partie à l’intérieur dudit corps (par exemple 514).

21. Appareil selon la revendication 20, dans lequel ledit fil métallique est à même de coulisser à l’intérieur dudit corps (par exemple 514).

22. Appareil selon la revendication 19, dans lequel l’appareil est un cathéter.

23. Appareil selon la revendication 1, comprenant en outre un manchon polymère tubulaire en position coaxiale avec au moins une partie dudit corps (par exemple 200 ou 514).

25. Appareil selon la revendication 1, dans lequel ladite extrémité distale (par exemple 208 ou 510) comprend un marqueur qui est essentiellement radio-opaque (par exemple 252).

26. Appareil selon la revendication 1, dans lequel l’appareil est un fil guide (par exemple 200, 300, 400, 420 ou 500).

27. Appareil selon la revendication 26, comprenant en outre un fil central plein (par exemple 501) fixé audit corps (par exemple 514).

28. Appareil selon la revendication 27, dans lequel ledit corps (par exemple 514) est tubulaire, au moins une partie dudit fil central (par exemple 501) étant disposée à l’intérieur dudit corps (par exemple 514).

29. Appareil selon la revendication 28, comprenant en outre une spirale (par exemple 508, 532 ou 538), au moins une partie dudit fil central (par exemple 501) étant disposée au sein de ladite spirale (par exemple 508, 532 ou 538).

30. Procédé pour construire un dispositif possédant une rigidité à la flexion relativement faible et une rigidité à la torsion relativement élevée pour faciliter la progression à travers une anatomie, le procédé comprenant au moins les étapes consistant à :

   procurer un corps (par exemple 200 ou 514) possédant une extrémité proximale (par exemple 204), une extrémité distale (par exemple 208 ou 510) et un axe longitudinal s’étendant au moins depuis l’extrémité proximale (par exemple 204) jusqu’à l’extrémité distale (par exemple 208 ou 510) ; découper un groupe (par exemple 570, 572 ou 574) d’au moins deux fentes (par exemple 220, 234, 238, 240, 264, 266, 274, 316, 544, 550, 570, 572 ou 574) dans ledit corps (par exemple 200 ou 514), chaque fente (par exemple 216, 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) étant essentiellement perpendiculaire à l’axe, et chaque fente (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) étant disposée essentiellement en position équidistante autour de l’axe ; dans n’importe quel ordre, faire tourner le corps (par exemple 200 ou 514) autour de l’axe en formant un angle et faire progresser le corps (par exemple 200 ou 514) le long de l’axe ; et répéter lesdites étapes de découpe et de mise en rotation et de progression, dans n’importe quel ordre, pour former une configuration hélicoïdale.

31. Procédé selon la revendication 30, dans lequel ladite découpe comprend le meulage avec une lame abrasive à diamant.

32. Procédé selon la revendication 30, dans lequel les fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) dudit groupe (par exemple 570, 572 ou 574) sont disposées essentiellement au même endroit axial.

33. Procédé selon la revendication 30, dans lequel le corps (par exemple 514) est tubulaire.

34. Procédé selon la revendication 30, dans lequel au moins plusieurs desdits groupes (par exemple 570, 572 ou 574) sont constitués par deux fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574).

35. Procédé selon la revendication 34, l’angle étant à peu près 85 degrés.

36. Procédé selon la revendication 34, dans lequel les fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) prennent la forme de poutres transversales (par exemple 552, 552A1 ou 552A2) et de poutres axiales (par exemple 546, 546A, 546B ou 546C), les fentes (par exemple 220, 234, 238, 240, 264, 266, 268, 274, 316, 544, 550, 570, 572 ou 574) possédant une profondeur (par exemple 553) et un espace (par exemple 353).
entre des groupes (par exemple 570, 572 ou 574), le procédé englobant en outre le fait de choisir la profondeur (par exemple 553) et l’espacement (par exemple 555) pour compenser de manière substantielle les contraintes qui s’exercent dans les poutres transversales (par exemple 552, 552A1 ou 552A2) et dans les poutres axiales (par exemple 546, 546A, 546B ou 546C).
