Description

BACKGROUND OF THE INVENTION

[0003] In WO99/56759 bone marrow stromal cells (BMSC) were induced to differentiate into neuron like phenotypes in vitro and in vivo by contacting such cells with growth factors (such as PDGF, GDNF, FGF2, NGF and BDNF) and retinoic acid (cis-9-retinoic acid, all-trans-retinoic acid or a combination thereof).

[0004] Evidence that MSCs injected into the lateral ventricles of neonatal mice can differentiate to astrocytes and neurofilament-containing cells lends support to this contention (Kopen et al., 1999, Proc. Natl. Acad. Sci. 96:10711-10716).

[0005] However, although differentiation of MSCs into astrocytes and glial cells had been demonstrated (WO 99/43286), to date, there has been no method for inducing MSCs to differentiate into neuronal cells. Thus, despite the crucial need for obtaining neuronal cells for treatment of CNS diseases, disorders, and conditions, no method has been available for obtaining large numbers of neuronal cells without encountering the technical and ethical hurdles involved in obtaining human NSCs or fetal tissue. The present invention overcomes this need.

BRIEF SUMMARY OF THE INVENTION

[0006] The present invention includes a method of inducing differentiation of an isolated marrow stromal cell into a neuronal cell. The method comprises transferring said marrow stromal cells into a serum free medium containing at least one neuronal differentiation-inducing compound. This induces differentiation of the isolated marrow stromal cell into a neuronal cell.

[0007] In one aspect, the isolated marrow stromal cell is a rat cell. Preferably, the isolated marrow stromal cell is a human cell.

[0008] The neuronal differentiation-inducing compound is an anti-oxidant. The anti-oxidant is selected from the group consisting of beta-mercaptoethanol, dimethylsulfoxide, butylated hydroxytoluene, butylated hydroxyanisole, ascorbic acid, dimethylfumarate, and n-acetylcysteine.

[0009] In another aspect, the anti-oxidant is beta-mercaptoethanol.

[0010] In another aspect, the anti-oxidant is dimethylsulfoxide. In yet another aspect the anti-oxidant is dimethylsulfoxide and butylated hydroxyanisole.

[0011] The invention further includes an in-vitro method of producing an isolated neuronal cell. The method comprises isolating a marrow stromal cell, transferring isolated marrow stromal cell into a cell free medium containing an antioxidant wherein the compound induces the isolated marrow stromal cell to differentiate into an isolated neuronal cell, thereby producing an isolated neuronal cell.

[0012] In addition, the invention includes the use of an isolated population of cells comprising neuronal cells obtained from a bone marrow sample from a human donor,
The neuronal cell population is then suitable for trans-isolated marrow cell into a neuronal cell recited above. The neuronal cell population includes an isolated neuronal cell population transfected with a therapeutic protein. The neuronal cell population encodes a cytokine, a chemokine, a neurotrophin, another trophic protein, a growth factor, an antibody, or a glioma toxic protein.

A preferred embodiment of the invention includes an isolated nucleic acid encoding a therapeutic protein that when expressed, and will effect treatment of a disease, disorder, or condition of the central nervous system. In an aspect of the invention, the therapeutic protein encoded by the isolated nucleic acid is a cytokine, a chemokine, a neurotrophin, another trophic protein, a growth factor, an antibody, or a glioma toxic protein.

The invention also includes an isolated population of cells comprising neuronal cells produced by an in vitro method comprising isolating a marrow stromal cell and transferring said marrow stromal cells into a serum free medium containing at least one antioxidant.

This induces the isolated marrow stromal cell to differentiate into isolated neuronal cells.

A transfected isolated population of cells comprising neuronal cells produced by isolating a marrow stromal cell and transferring said marrow stromal cells into a serum free medium containing at least one antioxidant is also included in the invention. The isolated population of cells comprising neuronal cell produced by this method are then transfected with an isolated nucleic acid encoding a therapeutic protein, that, when expressed in the neuronal cells, will effect treatment of a disease, disorder, or condition of the central nervous system.

In a preferred aspect, the therapeutic protein encoded by the isolated nucleic acid is a cytokine, a chemokine, a neurotrophin, another trophic protein, a growth factor, an antibody, or a glioma-toxic protein.

In an aspect of the present invention, the transfected population of cells comprising neuronal cells produced by contacting a neuronal differentiation-inducing compound with a marrow stromal cell is a rat cell. In another aspect, the transfected neuronal cells are rodent cells. In a preferred aspect, the transfected neuronal cells are human cells.
are shown in the drawings embodiment(s) which are presently preferred. It should be understood, however, that the invention is not limited to the precise arrangements and instrumentalities shown. In the drawings:

Figure 1A is a graph depicting fluorescent cell sorting of passage 1 rMSCs using mouse monoclonal antibodies that specifically bind with cell surface marker CD11b (CD11/integrin alpha M/Mac-1 alpha chain; Pharmingen, San Diego, CA) (unfilled peaks). The secondary antibody used was anti-mouse antibody conjugated with fluoresceine isothiocyanate (FITC). An isotype control is included in each experiment to identify background fluorescence (filled peaks). Number of cells analyzed (Events) is plotted on the Y-axis, while intensity of staining is plotted on the X-axis.

Figure 1B is a graph depicting fluorescent cell sorting of passage 1 rMSCs using mouse monoclonal antibodies that specifically bind with cell surface marker CD45/leukocyte common antigen (Pharmingen) (unfilled peaks). The secondary antibody is anti-mouse antibody conjugated with fluoresceine isothiocyanate (FITC). An isotype control is included in each experiment to identify background fluorescence (filled peaks). Number of cells analyzed (Events) is plotted on the Y-axis, while intensity of staining is plotted on the X-axis.

Figure 1C is a graph depicting fluorescent cell sorting of passage 1 rMSCs using mouse monoclonal antibodies that specifically bind with cell surface marker CD90/Thy-1/CD90.1/Thy1.1 (Pharmingen) (unfilled peaks). The secondary antibody is anti-mouse antibody conjugated with fluoresceine isothiocyanate (FITC). An isotype control is included in each experiment to identify background fluorescence (filled peaks). Number of cells analyzed (Events) is plotted on the Y-axis, while intensity of staining is plotted on the X-axis.

Figure 2, comprising Figures 2A-2H, is an image depicting neuronal differentiation of rMSCs at various time points after treatment. Briefly, the neuronal differentiation protocol disclosed herein was initiated at 0 minutes and followed for 210 minutes. Figure 2A represents 0 minutes, Figure 2B represents 30 minutes, Figure 2C represents 60 minutes, Figure 2D represents 90 minutes, Figure 2E represents 120 minutes, Figure 2F represents 150 minutes, Figure 2G represents 180 minutes, and Figure 2H represents 210 minutes. A flat rMSC in Figure 2A is identified (▼) prior to differentiation. Retraction of cell body and process elaboration is evident with increasing time. The arrow in Figure 2E indicates a second differentiating cell. Retracting neurite is indicated by (>). (Magnification = 200X).

Figure 3A is an image depicting neuron-specific enolase (NSE) expression in differentiating neurons using an anti-NSE polyclonal antibody (Polysciences, Warrington, PA). Briefly, undifferentiated rMSCs (indicated by a “<”) retained flattened morphology and stained only slightly for NSE expression. rMSC-derived neurons (arrows) stained dark brown for NSE expression and displayed condensed cell bodies and highly branches processes. Transitional cells (“~”) exhibited intermediate neuronal morphologies, with partially retracted cell bodies and light brown NSE staining.

Figure 3B is an image depicting that the morphologies of rMSC-derived neurons include simple bipolar (▼) and complex multipolar cells with highly branched processes (arrow). Intense NSE staining is evident in both neuronal cell types.

Figure 3C is an image depicting that NSE-positive neurons displaying pyramidal morphologies are sometimes generated using the protocols disclosed elsewhere herein. Contact with a transitional cell (light brown) is maintained via a single unbranched process.

Figure 3D is an image depicting a NSE-positive neuron elaborating a long process with evident varicosities (arrows). The data disclosed herein demonstrate that the neuronal cell body is in intimate contact with a transitional cell.

Figure 3E is an image depicting that clusters of rMSC-derived neurons of varying morphologies form complex networks. The data disclosed herein demonstrate that an undifferentiated rMSC (>•) is included within this meshwork of processes. (Magnification = 320X).

Figure 3F is an image of a Western blot analysis disclosing expression of low levels of NSE in uninduced rMSCs (U). The data disclosed herein demonstrate that a significant increase in NSE expression is evident at 5 hours post BME treatment (I). Comparable levels of tubulin are detected in each lane, indicating equal loading of samples.

Figure 4A is an image depicting NeuN expression in rMSC-derived neurons using a monoclonal anti-NeuN antibody (Chemicon, Temecula, CA). Briefly, the data disclosed herein demonstrate that NeuN can be detected in the nucleus and surrounding cytoplasm of rMSC-derived neurons (arrow). The data disclosed herein demonstrate that NeuN can be detected in the nucleus and surrounding cytoplasm of rMSC-derived neurons (arrow). Further, the data disclosed herein demonstrate that anti-NeuN antibody staining does not extend into the processes of positive cells.
The image further depicts that transitional cells (→) and undifferentiated rMSCs (←) do not express NeuN.

Figure 5A is an image depicting expression of NF-M and tau by differentiating cells. Briefly, rMSC-derived neurons were immunostained to detect expression of NF-M using an anti-NF-M polyclonal antibody (Chemicon). The data disclosed herein demonstrate that cells that exhibit neuronal morphologies express NF-M in both cell bodies (arrow) and processes (⁎). Flat, undifferentiated rMSCs (→) do not stain for NF-M expression.

Figure 5B is an image depicting that pre-adsorption of anti-NF-M antibody (Chemicon) with 20 micrograms of purified NF-M protein overnight at 4°C eliminated staining of rMSC-derived neurons, indicating specificity of the NF-M staining.

Figure 5C is an image depicting rMSC-derived neurons stained for expression of tau using anti-tau polyclonal antibody (Sigma Chemical Co., St. Louis, MO). The data disclosed herein demonstrate that cells displaying neuronal morphologies (arrows) stain dark brown for tau expression within the cell body and extending into the processes (⁎). Flat, undifferentiated rMSCs (→) do not express tau and are unstained. (Magnification = 320X).

Figure 5D is an image depicting rMSC-derived neurons stained for expression of tau using anti-tau polyclonal antibody (Sigma Chemical Co., St. Louis, MO). The data disclosed herein demonstrate that cells displaying neuronal morphologies (arrows) stain dark brown for tau expression within the cell body and extending into the processes (⁎). Flat, undifferentiated rMSCs (→) do not express tau and are unstained. (Magnification = 320X).

Figure 6A is an image depicting FM1-43 labeling of rMSC-derived neurons. The data disclosed herein demonstrate that rMSC-derived neurons depolarized using KC1 demonstrate intense labeling of terminal putative growth cones (indicated by unfilled triangle). Figure 6B is an image depicting FM1-43 labeling of rMSC-derived neurons. The data disclosed herein demonstrate that rMSC-derived neurons depolarized using KC1 demonstrate intense labeling of terminal putative growth cones (indicated by unfilled triangle).

Figure 7A is an image depicting differentiation of clonal rMSC lines.NSE-staining of individual rMSC clone #1 subjected to the differentiation protocol disclosed herein. NSE-positive cells (dark brown) are derived from each clonal line. Undifferentiated rMSCs (→) and/or transitional cells (←) are evident in each panel. (Magnification = 320X).

Figure 7B is an image depicting differentiation of clonal rMSC lines. NSE-staining of individual rMSC clone #2 subjected to the differentiation protocol disclosed herein. NSE-positive cells (dark brown) are derived from each clonal line. Undifferentiated rMSCs (→) and/or transitional cells (←) are evident in each panel. (Magnification = 320X).

Figure 7C is an image depicting differentiation of clonal rMSC lines. NSE-staining of individual rMSC clone #3 subjected to the differentiation protocol disclosed herein. NSE-positive cells (dark brown) are derived from each clonal line. Undifferentiated rMSCs (→) and/or transitional cells (←) are evident in each panel. (Magnification = 320X).

Figure 7D is an image depicting differentiation of clonal rMSC lines. NSE-staining of individual rMSC clone #1 subjected to the differentiation protocol disclosed herein. NSE-positive cells (dark brown) are derived from each clonal line. Undifferentiated rMSCs (→) and/or transitional cells (←) are evident in each panel. (Magnification = 320X).

Figure 7E is an image depicting differentiation of clonal rMSC lines. NSE-staining of individual rMSC clone #2 subjected to the differentiation protocol disclosed herein. NSE-positive cells (dark brown) are derived from each clonal line. Undifferentiated rMSCs (→) and/or transitional cells (←) are evident in each panel. (Magnification = 320X).

Figure 7F is an image depicting differentiation of clonal rMSC lines. NSE-staining of individual rMSC clone #3 subjected to the differentiation protocol disclosed herein. NSE-positive cells (dark brown) are derived from each clonal line. Undifferentiated rMSCs (→) and/or transitional cells (←) are evident in each panel. (Magnification = 320X).

Figure 8A is an image depicting differentiation of human MSCs. The data disclosed herein demonstrate that human MSCs differentiate into neurons and express high levels of NSE (dark brown). A lighter stained transitional cell (indicated by →) is depicted at lower left.

Figure 8B is an image depicting that an NSE-positive hMSC-derived neuron elaborates a process exhibiting neuronal-like terminal bulb morphology. Figure 8C is an image depicting a phase-contrast image of paired NSE-positive neurons. The data disclosed herein demonstrate growth cone morphologies with filopodial extensions (double arrow). The image is enlarged 50% to show detail.

Figure 8D is an image depicting that an NSE-positive hMSC-derived neuron elaborates a process exhibiting neuronal-like terminal bulb morphology. Figure 8E is an image depicting that an NSE-positive hMSC-derived neuron elaborates a process exhibiting neuronal-like terminal bulb morphology. Figure 8F is an image depicting that an NSE-positive hMSC-derived neuron elaborates a process exhibiting neuronal-like terminal bulb morphology.

Figure 9, comprising Figures 9A-9F, is an image depicting nestin and trkA expression in differentiating rMSC-derived neurons. Figures 9A-9C demonstrate cells stained for nestin expression at 5 hours, 1 day, and 6 days, respectively. Figures 9D-9F represent cells stained for trkA expression at 5 hours, 1 day, and 6 days, respectively. (Magnification = 320X).

DETAILED DESCRIPTION OF THE INVENTION

[0028] The invention is based on the discovery that contacting marrow stromal cells with an antioxidant as defined in the claims mediates differentiation of the cells into neuronal-like cells expressing a variety of neuron-specific markers (e.g., NeuN, neurofilament-M, neuron-specific enolase [NSE], tau, nestin, trkA, and the like). The cells exhibit other neuron-like phenotypic characteristics such as, but not limited to, spherical and refractile cell bodies exhibiting typical neuronal perikaryal appearance, cell bodies extending long processes terminating in growth cones and filopodia typical of neurons, and labeling of the growth cones by the fluorescent dye FM1-43, which typically labels neuronal transmitter release and synaptic vesicle recycling. Thus, the methods
Antioxidants disclosed herein induce marrow stromal cell differentiation into neuronal cells. Such methods are crucial in the development of cell-based therapeutics for treatment of central nervous system (CNS) disorders, diseases or conditions. Indeed, prior to the present invention, the lack of source of neuronal cells, which can be introduced into the CNS of a human patient, has severely impeded the development of CNS therapeutics.

Description

[0029] The invention includes a method of inducing an isolated marrow stromal cell to differentiate into an isolated neuronal cell (see claim 1). Embodiments of the method of the invention are defined in the claims and described in the Examples section herein. Generally, cells are isolated from a donor, stromal cells are obtained therefrom, usually using a cell-sorting method, and the stromal cells are subsequently cultured in vitro. The donor may be a rat, for example, or the donor may be a human. The invention is intended to encompass a mammalian donor and should not be limited to the specific donors disclosed herein.

[0030] To induce the neuronal phenotype, the cells are pre-treated with an effective amount of a neuronal differentiation-inducing compound which is introduced into the cell culture for a period of time. The length of time may vary according to the precise method being contemplated and should not be construed as limiting the invention in any way. After pre-treatment exposure to the neuronal differentiation inducing compound, the cells are transferred to a serum-free medium containing an amount of the same neuronal differentiation-inducing compound. Neuronal morphology is evident within about an hour, see Figure 2 for example, and the morphology becomes more evident steadily over time. Neuronal marker expression is also apparent within about 30 minutes after treatment. Neuronal cells so differentiated also eventually express several protein markers, including but not limited to, tyrosine hydroxylase, tubulin, choline acetyltransferase, synaptophysin, and TOAD, which are all proteins necessarily associated with neurons and neuronal processes.

[0031] These newly differentiated neuronal cells are useful in treating patients afflicted with diseases of the cholinergic and catecholaminergic systems, and more generally, patients afflicted with diseases of the central nervous system.

[0032] Antioxidants serve as the neuronal differentiation-inducing compounds, including but not limited to, beta-mercaptoethanol, dimethylsulfoxide, butylated hydroxytoluene, butylated hydroxyanisole, ascorbic acid, dimethylfumarate, and n-acetylcysteine. Particularly preferred embodiments as demonstrated in the Examples section herein disclosed, include beta-mercaptoethanol, dimethylsulfoxide and a combination of dimethylsulfoxide and butylated hydroxyanisole as the favored antioxidants. However, the invention is not limited to those antioxidants disclosed herein and should be construed to include all antioxidants, as well as other compounds which induce neuronal differentiation of marrow stromal cells.

[0033] The invention also illustrates use of growth factors as the neuronal differentiation-inducing compounds in the method of inducing differentiation of MSCs to neuronal cells. Such growth factors include, but are not limited to fibroblast growth factor 2, platelet-derived growth factor, and nerve growth factor, as well as related agents.

[0034] Neuronal identity can be confirmed by staining the differentiated neuronal cells for detection of neuron-specific markers. Examples of such markers are neurofilament-M (NF-M), tau protein, Neu-N, neuron-specific enolase (NSE), nestin, and trkA. Progressive differentiation of the marrow stromal cell to the neuronal cell corresponds with an increase in each of these markers, indicating that neuronal cells are produced. Further characterization can be accomplished using known immunocytochemical and antibody techniques. For example, immunocytochemical analysis of these neuronal cells reveals that the cells also express proteins that are associated with naturally-differentiated neurons. Such proteins include, but are not limited to tubulin, TOAD, and synaptophysin. Antibody detection of choline acetyltransferase and tyrosine hydroxylase may also be assessed.

[0035] It is apparent from the data disclosed herein that it is possible to differentiate isolated marrow stromal cell into neuronal cells in vitro. Neuronal cells so differentiated are useful in treating patients afflicted with any of a wide variety of central nervous system diseases, disorders, or conditions.

[0036] The invention also includes a method for producing an isolated neuronal cell from isolated marrow stromal cells as set forth in the claims (see claim 7). The method comprises differentiating an isolated marrow stromal cell in the same general manner as recited above, thereby producing an isolated neuronal cell. A population of cells comprising is defined in claims 13-12.

[0037] The isolated neuronal cell recited in both of the methods above may be transfected with an isolated nucleic acid encoding a therapeutic protein. The therapeutic protein, when expressed, will treat a patient having a disease, disorder, or condition of the central nervous system.

[0038] A wide plethora of beneficial proteins are well-known in the art and are set forth in, for example, WO 96/30031 and WO 99/43286. Such examples include, but are not limited to, cytokines, chemokines, neurotrophins, other trophic proteins, growth factors, antibodies, and glioma toxic protein. When the transfected neuronal cells encoding such proteins are administered to a patient, the neuronal cells will beneficially influence cells which are already present in the central nervous system. For example, transfected neuronal cells which are introduced into the central nervous system may be used to repair any central nervous system damage, and/or to...
combat tumors of the central nervous system.

[0039] International patent applications WO 96/30031 and WO 99/43286 also describe use of MSCs in therapies for a wide variety of CNS diseases, disorders, or conditions, which include, but are not limited to, genetic diseases of the CNS (e.g., Tay-Sachs’s, Sandhoffs disease, Hurler’s syndrome, Krabbe’s disease), birth-induced traumatic CNS injury, adult CNS diseases, disorders or conditions (e.g., Parkinson’s, Alzheimer’s, and Huntington’s diseases, elderly dementia, epilepsy, amyotrophic lateral sclerosis, multiple sclerosis, trauma, tumors, stroke, and the like) and degenerative diseases and traumatic injury of the spinal cord.

[0040] Among neonates and children, transfected neuronal cells may be used for treatment of a number of genetic diseases of the CNS and peripheral nerves and they also have non-neurological effects. While the non-neurological effects of these diseases may be treatable by bone marrow transplantation, the central nervous system effects do not improve despite bone marrow transplantation. The method of the present invention is useful to address the central nervous system effects of these types of diseases. In addition, in neonates and children, head trauma during birth or following birth is treatable by introducing these neuronal cells directly into the central nervous system of the children. Central nervous system tumor formation in children is also treatable using the methods of the present invention.

[0041] Adult diseases of the central nervous system are also treatable by administering isolated neuronal cells to the adult. Such adult diseases include but are not limited to, Parkinson’s disease, Alzheimer’s disease, spinal cord injury, stroke, trauma, tumors, degenerative diseases of the spinal cord such as amyotrophic lateral sclerosis, Huntington’s disease and epilepsy. Treatment of multiple sclerosis is also contemplated.

[0042] Treatment of spinal cord injuries is also contemplated by the present invention. Prior art methods of treating spinal cord injuries involve using fibroblast cells to deliver neurotrophins to the site of spinal cord lesions in animals. The neurotrophins, delivered in this manner, reduce the lesion or otherwise treat the injury. However, fibroblasts produce large amounts of collagen, causing fibrosis at the site of the lesion, thus negating the beneficial effects of the treatment. Delivery of neurotrophins to spinal cord lesions using transfected neuronal cells is advantageous over prior art methods because neuronal cells do not produce large amounts of collagen and therefore should not cause fibrosis.

[0043] The invention further contemplates treating a human patient having a disease, disorder, or condition of the central nervous system by administering the differentiated neuronal cells of the invention to the central nervous system of the patient as defined in the claims (see claims 8-12). Methods of treating a human patient using MSCs are described in WO 96/30031 and WO 99/43286, which are incorporated by reference as if set forth in their entirety herein. Methods of administering differentiated neuronal cells to a patient are identical to those used for MSCs as described in WO 96/30031 and WO 99/M3286. The methods encompass introduction of an isolated nucleic acid encoding a beneficial protein into differentiated neuronal cells and also encompassing differentiated neuronal cells themselves in cell-based therapeutics where a patient is in need of the administration of such cells. The differentiated neuronal cells of the present invention are preferably to be administered to a human, and further, the neuronal cells are preferably to be administered to the central nervous system of the human. In some instances, the differentiated neuronal cells are to be administered to the corpus striatum portion of the human brain. The precise site of administration of the neuronal cells will depend on any number of factors, including but not limited to, the site of the lesion to be treated, the type of disease being treated, the age of the human and the severity of the disease, and the like. Determination of the site of administration is well within the skill of the artisan versed in the administration of cells to mammals.

[0044] The mode of administration of the differentiated neural cells to the central nervous system of the human may vary depending on several factors including but not limited to, the type of disease being treated, the age of the human, whether the neuronal cells have isolated DNA introduced therein, and the like. An example of administration of neuronal cells directly into brain tissue is provided herein in the experimental details section. Generally, cells are introduced into the brain of a mammal by first creating a hole in the cranium through which the cells are passed into the brain tissue. Cells may be introduced by direct injection, by using a shunt, or by any other means used in the art for the introduction of compounds into the central nervous system.

Definitions

[0045] The articles "a" and "an" are used herein to refer to one or to more than one (i.e. to at least one) of the grammatical object of the article. By way of example, "an element" means one element or more than one element.

[0046] As used herein, "central nervous system" should be construed to include brain and/or the spinal cord of a mammal. The term may also include the eye and optic nerve in some instances.

[0047] As used herein, "stromal cells", "isolated marrow stromal cells", and "MSCs" are used interchangeably and are meant to refer to the small fraction of cells in bone marrow which can serve as stem cell-like precursors of osteocytes, chondrocytes, and adipocytes and which are isolated from bone marrow by their ability adhere to plastic dishes. Marrow stromal cells may be de-
rived from any animal. In some embodiments, stromal cells are derived from primates, preferably humans.

As used herein, the term "anti-oxidant" is meant to refer to those substances that inhibit oxidation or reactions promoted by oxygen or peroxides. Examples of anti-oxidants include, but are not limited to, beta-mercaptoethanol, dimethylsulfoxide, butylated hydroxytoluene, butylated hydroxyanisole, ascorbic acid, dimethylfumarate, and n-acetylcysteine.

As used herein, the terms "beneficial protein" and "therapeutic protein"are used interchangeably and are meant to refer to a protein which can compensate for the protein encoded by a defective gene and/or insufficient gene expression that is causally linked to the disease or symptoms of the disease, disorder or condition characterized by a gene defect. The presence of the protein alleviates, reduces, prevents or causes to be alleviated, reduced or prevented, the causes and/or symptoms that characterize the disease, disorder or condition.

As used herein, a disease, disorder or condition which can be treated with a beneficial or therapeutic protein is meant to refer to a disease, disorder or condition that can be treated or prevented by the presence of a protein which alleviates, reduces, prevents or causes to be alleviated, reduced or prevented, the causes and/or symptoms that characterize the disease, disorder or condition. Diseases, disorders and conditions which can be treated with a beneficial protein include diseases, disorders and conditions characterized by a gene defect as well as those which are not characterized by a gene defect but which nonetheless can be treated or prevented by the presence of a protein which alleviates, reduces, prevents or causes to be alleviated, reduced or prevented, the causes and/or symptoms that characterize the disease, disorder or condition.

The term "isolated nucleic acid" should be construed to mean the induction of a differentiated transfection), electroporation, microinjection, liposome-mediated transfer, chemical-mediated transfer, ligand mediated transfer or recombinant viral vector transfer.

The term "differentiation" as used herein, should be construed to mean the induction of a differentiated phenotype in an undifferentiated cell by coculturing the undifferentiated cell in the presence of a substantially homogeneous population of differentiated cells, in the presence of products of differentiated cells or in the presence of an inducer of cell differentiation.

As used herein should be construed to mean an MSC differentiated such that it expresses at least one of the following neuronal markers: neuron-specific enolase (NSE), NeuN, neurofilament M, or tau protein.

The term "neuronal cell" as used herein should be construed to mean a nerve cell capable of receiving and conducting electrical impulses from the central nervous system. A nerve cell or "neuron" typically comprises a cell body, an axon, axon terminals, and dendrites.

The term "neuronal differentiation-inducing compound" is meant to refer to those compounds capable of inducing differentiation of a stromal cell into a neuronal cell. These compounds include, but are not limited to antioxidants, trophic factors, and growth factors.

The invention is further described in detail by reference to the following experimental examples. These examples are provided for purposes of illustration only, and are not intended to be limiting unless otherwise specified. Thus, the invention should in no way be construed as being limited to the following examples, but rather, should be construed to encompass any and all variations as defined in the claims which become evident as a result of the teaching provided herein.

**EXAMPLES**

The experiments presented in this example may be summarized as follows.

Bone marrow stromal cells exhibit multiple traits of a stem cell population. They can be greatly expanded in vitro, and induced to differentiate into multiple mesenchymal cell types (see, e.g., WO 96/30031; WO 99/43286). However, differentiation to non-mesenchymal fates has not been demonstrated. Here, adult rat stromal cells were expanded as undifferentiated cells in culture for more than 14 passages, indicating their proliferative capacity. Further, a novel treatment protocol induced the stromal cells to exhibit a neuronal phenotype, expressing various neuron-specific markers, i.e., neuron-specific enolase (NSE), NeuN, neurofilament-M, tau, nestin, and trkA.

Moreover, the refractile cell bodies of the treated cells extended long processes terminating in growth cones and filopodia typical of neuronal cells. The fluorescent dye, FM1-43, labeled growth cones, consistent with transmitter release and synaptic vesicle recycling by the treated cells. Clonal cell lines, established from single cells, proliferated, yielding both undifferentiated and cells exhibiting a neuronal phenotype.

Human marrow stromal cells treated using the novel protocol disclosed herein differentiated into neurons similarly to rMSCs demonstrating that the protocol...
is not limited to rodent stromal cells. Consequently, the data disclosed herein demonstrate, for the first time, that mammalian marrow stromal cells can be induced to overcome their mesenchymal commitment, and can constitute an abundant and accessible cellular reservoir for the treatment of a variety of neurologic diseases, disorders or conditions.

[0062] The Materials and Methods used in the experiments presented in this example are now described.

Cell culture

[0063] Rat MSCs were originally cultured in alpha-Medium (alpha-MEM) supplemented with 20% FBS, 2 mM L-glutamine, 100 units per milliliter penicillin, 100 milligrams per milliliter streptomycin and 25 nanograms per milliliter amphotericin B. For each passage the cells were plated at about 8,000 cells per square centimeter and grown to confluency. At passage the cells were maintained for an additional 30 minutes in serum-free medium (SFM) for approximately 4 hours. The cultures were transferred to DMEM (pH 8.0)/20% FBS without additional supplementation, and maintained beyond passage 14. The rat MSCs were obtained with a protocol and procedures approved by the Institutional AUC. The human samples were obtained from volunteers with informed consent and according to a protocol approved by the Institutional Review Board.

Western Blot

[0064] Thirty milligrams of protein extract from untreated (U) and BME-induced (I) rMSC cultures was separated on a 4%-20% gradient acrylamide gel and electrophoretically transferred to a nylon membrane. The Western blot was probed for tubulin expression using an anti-tubulin monoclonal antibody (Sigma Chemical Co., St. Louis, MO) followed by secondary antibody conjugated with horse radish peroxidase (HRP). Color development was performed using enhanced chemiluminescence reagents (Amersham, Piscataway, NJ). The blot was then stripped and probed for NSE expression using anti-NSE polyclonal antibody (ICN). Again, the secondary antibodies were HRP-conjugated, and color was developed using ECL reagents.

Immunocytochemistry

[0065] Cultured rMSCs were fixed with 4% paraformaldehyde, incubated with primary antibody overnight at 4°C, incubated with secondary antibody for one hour, followed by exposure to avidin-biotin complex for one hour at 25°C. Diaminobenzidene (DAB) served as chromogenic substrate for HRP.

FM1-43 Labeling

[0066] Cultures were treated with DMSO/BHA in serum-free media (SFM) for approximately 4 hours. The cells were maintained for an additional 30 minutes in artificial cerebral spinal fluid (aCSF)/BHA. Cells were labeled in aCSF containing 1 millimolar FM1-43 and 75 mM KCl for 60 seconds. The labeling mixture was removed, the cultures were washed twice with aCSF, and the cells were incubated in aCSF for 60 minutes to reduce background staining. Cultures were fixed with 4% paraformaldehyde, and soaked for 24 hours in phosphate buffered saline (PBS) before analysis.

[0067] The Results of the experiments presented in this example are now described.

Stromal Cell Characterization

[0068] Rat mesenchymal stromal cells (rMSCs) were isolated from the femurs of adult rats and propagated in vitro (Azizi et al., 1998, Proc. Natl. Acad. Sci. USA 95:3908-3913). The data disclosed in Figure 1A demonstrate that the distribution of cells stained with antibody to CD 11b (unfilled) does not differ from that of isotype control (filled), indicating the MSC cultures do not contain significant numbers of contaminating CD11b-expressing cells. Further, the data disclosed in Figure 1B also demonstrate that the intensity of staining does not differ between CD45 antibody (unfilled) and control (filled) profiles, indicating that cultured rMSCs are not contaminated by CD45-expressing cells. Fluorescent cell sorting at passage one also demonstrated that the cells were negative for CD11b (Figure 1A), and CD45 (Figure 1B), which are cell surface markers associated with lymphohematopoietic cells. Therefore, there was no evidence of hematopoietic precursors in the cultures.

[0069] In contrast, the data disclosed herein demonstrate that rMSCs expressed CD90 (Figure 1C), consistent with their undifferentiated state. At low plating densities rMSCs grew as a monolayer of large, flat cells. As the cells approached confluency, they assumed a more spindle-shaped, fibroblastic morphology. At the outset of the neuronal differentiation studies disclosed elsewhere herein, untreated rMSCs were further characterized by staining for the cell surface markers CD44 and CD71. Cells were positive for CD44 and CD71 expression, consistent with previous reports (Pittenger et al., 1999, Science 284:143-147; Bruder et al., 1998, Clin. Orthop. Relat. Res. 355S:S247-S256).

Neuronal Differentiation

[0070] To induce the neuronal phenotype, rMSCs were initially maintained in sub-confluent cultures in media supplemented with 1 mM beta-mercaptoethanol (BME) for 24 hours. Under these conditions no changes in morphology were evident. To effect neuronal differentiation, the cells were transferred to serum-free medium containing 1-10 millimolar BME (SFM/BME). The percentage of cells adopting a neuronal morphology increased at higher BME concentrations, and was enhanced by BME pretreatment. Within 60 minutes of exposure to SFM/BME changes in morphology of some of
the rMSCs were apparent (Figure 2C). Responsive cells progressively assumed neuronal morphological characteristics over the first 3 hours. Initially, cytoplasm in the flat rMSCs retracted towards the nucleus, forming a contracted multipolar, cell body, leaving membranous, process-like extensions peripherally (0-90 minutes).

[0071] Treated cells exhibited increased expression of the neuronal marker NSE within 30 minutes of treatment. Over the subsequent 2 hours cell bodies became increasingly spherical and refractile, exhibiting a typical neuronal perikaryal appearance. Processes continued to elaborate, developing growth cone-like terminal expansions and filopodial extensions (see, e.g., Figures 2G and 2H). Cellular processes exhibited primary and secondary branches, and underwent dynamic growth. Retraction, as well as extension, was evident as demonstrated by the fact that the cell marked by an arrow at 120 minutes (Figure 2E) was initially contacted by a neighboring process (marked by “>”), which retracted by 180 minutes (Figure 2G), with loss of contact.

[0072] To further characterize potential neuronal differentiation, BME-treated cultures were stained to detect expression of the neuronal marker neuron-specific enolase (NSE). Unresponsive, flat rMSCs expressed very low, but detectable, levels of NSE protein, consistent with previous detection of minute amounts of protein and/or message in cells of bone marrow origin (Pechumer et al., 1993, Lab. Invest. 89:743-749; Reid et al., 1991, Clin. Pathol. 44:483-486; vanObberghen et al., 1988, J. Neurosci. Res. 19:450-456).

[0073] Progressive transition of rMSCs to a neuronal phenotype coincided with increased expression of NSE (Figure 3A). Cells that exhibited contracted cell bodies and processes stained dark brown for NSE expression (arrows), while flat, unresponsive rMSCs (>), displayed minimal NSE staining. Cells at intermediate stages in the differentiation sequence (→) exhibited transitional morphologies and light brown staining, indicating synchrony of morphologic and molecular differentiation. rMSC-derived neurons displayed distinct neuronal morphologies (Figure 3B), ranging from simple bipolar (▼) to large, extensively branched multipolar cells (arrow). Rare NSE-positive neurons exhibited pyramidal cell morphologies (Figure 3C), while neurons elaborating long processes with evident varicosities (arrows) were more common (Figure 3D). Clusters of differentiated cells exhibited intense NSE positivity, and processes formed extensive networks (Figure 3E). Even within these clusters, typical, flat rMSCs (>), were only lightly stained, consistent with their undifferentiated state.

[0074] Western blot analysis (Figure 3F) confirmed the expression of low levels of NSE protein in uninduced rMSCs. Induction of the neuronal phenotype resulted in a dramatic increase in NSE expression, consistent with the immunocytochemical data.

[0075] To further investigate neuronal characteristics, differentiated cultures were stained for NeuN, a neuron-specific marker expressed in post-mitotic cells (Sarnat et al., 1998, Brain Res. 20:88-94). A subset of cells exhibiting rounded cell bodies and processes (arrow) stained for NeuN expression, while undifferentiated cells (<) remained NeuN-negative (Figure 4A). Consistent with previous reports describing NeuN staining of neuronal cells (Sarnat et al., 1998, Brain Res. 20:88-94), NeuN staining was confined to the nucleus and surrounding cytoplasm of positive cells, and did not extend into the processes. Some cells exhibiting distinct neuronal morphologies did not express NeuN (→), while neighboring cells were intensely positive (arrow) (Figure 4B). This pattern contrasts with that established for NSE staining, where every cell exhibiting a neuronal morphology demonstrated increased NSE expression. Without wishing to be bound by any particular theory, these data suggest that a subset of NSE-positive cells are post-mitotic neurons. Also without wishing to be bound by any particular theory, it may be that the anti-oxidant properties of BME, which enhance neuronal survival in vitro (Ishii et al., 1993, Neurosci. Lett. 163:159-162), may mediate, in part, induction of neuronal differentiation in MSCs although this surprising result was unexpected based on prior studies.

[0076] Nestin, an intermediate filament protein, is expressed in neuroepithelial neuronal precursor stem cells, with expression decreasing as the neuron matures. Experimental data shows that when the MSC-differentiated neuronal cells are stained to detect nestin, the expression of nestin decreases over time (Figures 9A-9C). Further, staining for trkA, a high-affinity nerve growth factor receptor which is present in neurons, demonstrates that trkA levels remain unchanged throughout the maturation process of the MSC-differentiated neuronal cell (Figures 9D-9F).

[0077] To begin examining the hypothesis that the anti-oxidant properties of BME mediated induction of neuronal differentiation in MSCs, rMSCs were treated with other anti-oxidants, e.g., dimethylsulfoxide (DMSO), butylated hydroxyanisole (BHA), or butylated hydroxytoluene (BHT), ascorbic acid, dimethyl fumarate, n-acetylcysteine, and the like, both alone and in combination with each other. Further, treatment with the anti-oxidant dithiothreitol (DTT) in combination with BHA also induced neuronal differentiation by MSCs suggesting that DTT alone may also elicit neuronal differentiation.

[0078] Each anti-oxidant treatment (e.g., DMSO, BHA, BHT, ascorbic acid, dimethylfumarate, n-acetylcysteine, and the like, both alone and in combination) elicited neuronal morphologies with a time course similar to the effects of BME. Additionally, preliminary data suggested that treatment using about 2% (v/v) DMSO and about 200 millimolar BHA (DMSO/BHA) was preferred although a wide range of concentrations elicited neuronal differentiation.

[0079] To further characterize neuronal identity, MSCs treated with DMSO/BHA were stained for neurofilament-M (NF-M), a neuron-specific intermediate filament that helps initiate neurite elongation (Carden et al., 1987, Neurosci. 7:3489-3504). The data disclosed previously
Clonal Analysis

Human Stromal Cells Differentiate into Neurons

derived from a single cell can give rise to both rMSCs (process-) and differentiated into NSE-positive neurons after BME treatment. Figure 7A.

DMSO/BHA treated cultures were then examined for the presence of tau, a neuron-specific microtubule-associated protein expressed by differentiating neurons (Kosik and Finch, 1987, J. Neurosci. 7:3142-3153). Cells exhibiting a neuronal morphology (arrow) expressed tau protein in the cell body as well as in the processes (*), while undifferentiated flat cells were tau-negative (-) (Figures 5C and 5D). The data disclosed herein indicate that the method described herein induce neuronal differentiation of marrow stromal cells.

Activity-Dependent Synaptic Vesicle Recycling

To further characterize neuronal properties, cultures were treated with the styryl dye FM1-43, which labels the outer leaflet of synaptic vesicles upon activity-dependent transmitter release (Betz and Bewick, 1992, Science 255:200-203; Betz et al., 1992, J. Neurosci. 12:363-375; Diefenbach et al., 1999, J. Neurosci. 19:9436-9444). Exposure to depolarizing concentrations of K+ resulted in fluorescent labeling of growth cones (→), suggesting that the cells were recycling synaptic vesicles consequent to activity-dependent transmitter release.

Clonal Analysis

To determine whether individual rMSCs exhibit stem cell characteristics of self-renewal and pluripotentiality, individual clones were analyzed. To establish clones, rMSCs were plated at approximately 10 cells per square centimeters, grown to 50-150 cells per colony, isolated with cloning cylinders, transferred to separate wells and eventually to individual flasks. Single cells replicated as typical rMSCs and differentiated into NSE-positive neurons after BME treatment.

Analysis of four distinct clonal lines is shown in Figure 7A-7D. Each individual clone generated refractile, process-bearing, NSE-positive cells following BME treatment. Undifferentiated rMSCs (>) and transitional cells (→) were evident in each clonal line. Therefore, clones derived from a single cell can give rise to both rMSCs and neurons, indicating stem cell characteristics.

Human Stromal Cells Differentiate into Neurons

The neuronal potential of MSCs was not unique to rodents as demonstrated by the following experiments using MSCs obtained from humans (hMSCs). hMSCs were isolated from a healthy adult donor and grown in vitro (Bjornson et al., 1999, Science 283:534-537). hMSCs resembled their rodent counterparts, growing as large flat cells in the undifferentiated state.

Cells from passage two were subjected to the neuronal differentiation protocol and stained for NSE or NF-M expression. After BME treatment, hMSCs attained neuronal characteristics and increased NSE expression in a time frame similar to that observed for rMSCs. Contracted cell bodies elaborated processes and stained strongly for NSE expression within 3 hours (Figures 8A and 8B). Transitional cells were also evident (→). Many processes elaborated by hMSC-derived neurons exhibited terminal bulbs (arrow in 8B), which may represent growth cones. Growth cone morphologies with filopodial extensions (→) were clearly evident on the processes elaborated by paired neurons depicted in the image in Figure 8C. These cells also expressed NF-M, consistent with their neuronal differentiation (Figure 8D).

To the best of Applicants' knowledge, this is the first report that peripheral mesenchymal cells can differentiate into neurons in vitro. Further, the present invention provides, for the first time, methods of directing differentiation of MSCs into neuronal cells in vitro. MSCs are useful in the treatment of a wide variety of neurologic diseases disorders and conditions, and these cells offer significant advantages over other so-called "stem" cells. That is, bone marrow cells are readily accessible, obviating the risks of obtaining neural stem cells from the brain, and provide a renewable population which can be expanded in vitro thereby allowing complex gene manipulations to be performed for ex vivo gene therapy and/or for cell therapy for CNS diseases, disorders or conditions that require administering cells to a CNS site. Furthermore, autologous transplantation overcomes the ethical and immunologic concerns associated with the use of fetal tissue. Moreover, MSCs grow rapidly in culture, precluding the need for immortalization, and differentiate into neurons exclusively using the protocols disclosed herein.
Expression of Neuronal Proteins in MSC-Differentiated Neuronal Cells

[0088] The data disclosed herein demonstrates that neuronal cells differentiated from MSCs as described herein express various neuron-related proteins. For example, immunocytochemical analysis of these differentiated neurons revealed the expression of beta-3 tubulin. Further, TOAD-64, a neuronal protein of unknown function, is also detectable using immunocytochemical techniques, as well as synaptophysin, which is associated with synapses and synaptic vesicles. Using polyclonal and monoclonal antibody-based procedures, these cells have been demonstrated to express choline acetyltransferase, an enzyme responsible for the synthesis of the neurotransmitter acetylcholine. Finally, tyrosine hydroxylase, the rate-limiting enzyme in catecholamine biosynthesis, was also detected immunocytochemically in a population of these differentiated neurons.

[0089] It is apparent that due to the presence of these neuronal gene products, the differentiated neurons may be therapeutically beneficial to treating those diseases affecting cholinergic and catecholaminergic systems, such as, for example, Alzheimer’s disease, Parkinson’s disease, or schizophrenia.

Transplantation of the Differentiated Neurons to Experimental Animals

[0090] The differentiated neurons generated as described herein, were further tested to determine their viability in vivo. The neurons were transplanted, using sterile technique and known and accepted neurosurgical procedures (1997, Grill et al.; 1995, Gage et al.; 1994, Dunnett et al.), into the hippocampus or striatum of the brain or the dorsal horn of the spinal cord of individual rats. Each rat received a transplant to one of the aforementioned areas. The rats were returned to their cages and received standard postoperative care with access to food and water ad libitum.

[0091] To determine whether neuron viability was maintained in vivo, a post-operative study of the rats receiving the transplant was conducted. Rats receiving the neuronal transplant were examined 42 days after the transplantation operation took place. Using fluorescence microscopy to detect bisbenzimide-positive transplanted cells, histologic studies of the hippocampal and striatal regions of the brain revealed that the transplanted neurons survived in the hippocampus. This result indicates that long-term survival of the transplanted, differentiated neurons is possible. An examination of the rats receiving the transplanted neurons in the dorsal horn of the spinal cord demonstrated a survival period of at least three days. Further, the processes of the transplanted neurons in this area grew to at least two to three times in length than the cell body diameter.

[0092] As is evident from these results, transplanted, differentiated neurons express many neuronal proteins, retain viability in vivo, and seemingly exert no detectable deleterious effect on the living animal. As a result, these neurons create a potential therapeutic treatment for a variety of brain and spinal cord diseases, including, but not limited to, Alzheimer’s disease, Parkinson’s disease, Schizophrenia, and spinal cord injury resulting from trauma or degeneration.

[0093] While the invention has been disclosed with reference to specific embodiments it is apparent that other embodiments and variations of this invention as defined in the claims may be devised by others skilled in the art without departing from the true spirit and scope of the invention. The appended claims are intended to be construed to include all such embodiments and equivalent variations.

Claims

1. A method of inducing differentiation of an isolated marrow stromal cell into a neuronal cell, said method comprising transferring isolated marrow stromal cells into a serum free medium containing at least one anti-oxidant, thereby inducing differentiation of said isolated marrow stromal cell into a neuronal cell.

2. The method of claim 1, wherein said isolated marrow stromal cell is a human cell.

3. The method of claim 1 or 2, wherein said anti-oxidant is selected from the group consisting of beta-mercaptoethanol, dimethylsulfoxide, butylated hydroxytoluene, butylated hydroxyanisole, ascorbic acid, dimethylfumarate, and nacetylcysteine.

4. The method of claim 3, wherein said anti-oxidant is betamercaptoethanol.

5. The method of claim 3, wherein said anti-oxidant is dimethylsulfoxide.

6. The method of claim 3, wherein said anti-oxidant is dimethylsulfoxide and butylated hydroxyanisole.

7. An in vitro method of producing an isolated neuronal cell, said method comprising isolating a marrow stromal cell, transferring isolated marrow stromal cells into a serum free medium containing an anti-oxidant wherein said anti-oxidant induces said isolated marrow stromal cell to differentiate into an isolated neuronal cell, thereby producing said isolated neuronal cell.

8. Use of an isolated population of cells comprising neuronal cells obtained from a bone marrow sample from a human donor, after isolation of stromal cells from said bone marrow sample and induction of said stromal cells to differentiate into isolated neuronal
cells by transferring isolated marrow stromal cells into a serum free medium containing at least one anti-oxidant, for preparing a medicament for effecting treatment of a disease, disorder, or condition of the central nervous system of a human patient.

9. The use of claim 8, wherein said disease, disorder, or condition of the central nervous system is selected from the group consisting of Alzheimer's disease, Parkinson's disease, Huntington's disease, amyotrophic lateral sclerosis, a tumor, a trauma, elderly dementia, Tay-Sach's disease, Sandhoff's disease, Hurler's syndrome, Krabbe's disease, birth-induced traumatic central nervous system injury, epilepsy, multiple sclerosis, trauma, tumor, stroke, and spinal cord injury.

10. The use of claim 8, wherein said isolated neuronal cells had been transfected with an isolated nucleic acid encoding a therapeutic protein, wherein said protein is expressed in said cells serves to effect treatment of said disease, disorder, or condition.

11. The use of claim 10, wherein said isolated nucleic acid encodes a therapeutic protein selected from the group of a cytokine, a chemokine, a neurotrophin, another trophic protein, a growth factor, an antibody, and a glioma toxic protein.

12. Use of a population of cells comprising neuronal cells obtained from marrow stromal cells of a human patient, after propagation of said marrow stromal cells in culture under conditions that induce their differentiation into neuronal cells, induced by transferring isolated marrow stromal cells into a serum free medium containing an anti-oxidant, for preparing a medicament for treatment of a human patient in need of said neuronal cells.

13. An isolated population of cells comprising neuronal cells made by a method of inducing differentiation of an isolated marrow stromal cell, said method comprising transferring isolated marrow stromal cells into a serum free medium containing at least one anti-oxidant, thereby inducing differentiation of said isolated marrow stromal cell into said neuronal cell.

14. The population of claim 13, wherein said cells are human cells.

15. An isolated population of cells comprising neuronal cells made by a method of inducing differentiation of an isolated marrow stromal cell, said method comprising transferring isolated marrow stromal cells into a serum free medium containing at least one anti-oxidant, thereby inducing differentiation of said isolated marrow stromal cell into said neuronal cells, wherein said neuronal cells are further transfected with an isolated nucleic acid encoding a therapeutic protein, and further wherein, when said protein is expressed in said cells said protein serves to effect treatment of a disease, disorder, or condition of the central nervous system.

16. The population of claim 15, wherein said isolated nucleic acid encodes a protein selected from the group consisting of a cytokine, a chemokine, a neurotrophin, another trophic protein, a growth factor, an antibody, and a glioma toxic protein.

17. The population of claim 15, wherein said cells are human cells.

18. An isolated population of cells comprising neuronal cells made by an in vitro method of producing an isolated neuronal cell, said method comprising isolating a marrow stromal cell, transferring isolated marrow stromal cells into a serum free medium containing an anti-oxidant, wherein said anti-oxidant induces said isolated marrow stromal cells to differentiate into said isolated neuronal cell, thereby producing said isolated population comprising neuronal cells.

19. The population of claim 18, wherein said cells are human cells.

20. An isolated population of cells comprising neuronal cells made by an in vitro method of producing an isolated neuronal cell, said method comprising isolating a marrow stromal cell, transferring isolated marrow stromal cells into a serum free medium containing an anti-oxidant, wherein said anti-oxidant induces said isolated marrow stromal cells to differentiate into said isolated neuronal cells, thereby producing said isolated neuronal cells, wherein said neuronal cells are further transfected with an isolated nucleic acid encoding a therapeutic protein, and further wherein when said protein is expressed in said cells, said protein serves to effect treatment of a disease, disorder, or condition of the central nervous system.

21. The population of claim 20, wherein said isolated nucleic acid encodes a protein selected from the group consisting of a cytokine, a chemokine, a neurotrophin, another trophic protein, a growth factor, an antibody, and a glioma toxic protein.

22. The population of claim 21, wherein said cells are human cells.

**Patentansprüche**

1. Ein Verfahren zum Induzieren der Differenzierung
von einer isolierten Markstromazelle in eine neuronale Zelle, das Verfahren umfassend ein Transferieren isolierter Markstromazellen in ein Serum-freies Medium enthaltend wenigstens ein Antioxidationsmittel, und dadurch Induzieren der Differenzierung von besagter isolierter Markstromazelle in eine neuronale Zelle.

2. Verfahren gemäß Anspruch 1, wobei die isolierte Markstromazelle eine menschliche Zelle ist.

5. Verfahren gemäß Anspruch 3, wobei das Antioxidationsmittel Dimethylsulfoxid ist.

6. Verfahren gemäß Anspruch 3, wobei das Antioxidationsmittel Dimethylsulfoxid und butyliertes Hydroxyanisol ist.

10. Verwendung gemäß Anspruch 8, wobei die isolierten neuronalen Zellen mit einer ein therapeutisches Protein kodierenden isolierten Nukleinsäure transfiziert wurden, wobei das Protein in besagten Zellen exprimiert wird und dazu dient, eine Behandlung von der Krankheit, der Funktionsstörung oder des Zustandes zu bewirken.

12. Verwendung von einer Zellpopulation umfassend neuronale Zellen zur Herstellung eines Arzneimittels für die Behandlung von einem menschlichen Patienten, der die neuronalen Zellen benötigt, wobei die neuronalen Zellen aus Markstromazellen eines menschlichen Patienten erhalten wurden, nach einem Vermehren dieser Markstromazellen in einer Kultur unter Bedingungen, welche die Differenzierung der Markstromazellen in neuronale Zellen induzieren, wobei induziert wurde durch Transferieren der isolierten Markstromazellen in ein Serum-freies Medium enthaltend ein Antioxidationsmittel.

15. Eine isolierte Zellpopulation umfassend neuronale Zellen, die durch ein Verfahren zum Induzieren einer Differenzierung von einer isolierten Markstromazelle hergestellt wurden, wobei dieses Verfahren umfasst ein Transferieren isolierter Markstromazellen in ein Serum-freies Medium enthaltend wenigstens ein Antioxidationsmittel, und dadurch Induzieren der Differenzierung von den isolierten Markstromazellen in
18. Eine isolierte Zellpopulation umfassend neuronale Zellen, wobei die neuronalen Zellen ferner transfi ziert werden mit einer ein therapeutisches Protein kodierenden Nukleinsäure, und wobei ferner, wenn das Protein in den Zellen exprimiert wird, das Protein dazu dient, die Behandlung von einer Krankheit, einer Funktionsstörung oder einem Zustand des zentralen Nervensystems zu bewirken.

20. Eine isolierte Zellpopulation umfassend neuronale Zellen, die durch ein in vitro-Verfahren zum Herstellen einer isolierten neuronalen Zellen hergestellt wurden, wobei dieses Verfahren umfasst ein Isolieren von Markstromazellen, ein Transferieren isolierter Markstromazellen in ein Serum-freies Medium enthaltend ein Antioxidationsmittel, wobei das Antioxidationsmittel ein Differenzieren der isolierten Markstromazellen in die isolierte neuronale Zellen induziert, und dadurch Herstellen von diesen isolierten neuronalen Zellen, wobei die neuronalen Zellen ferner mit einer ein therapeutisches Protein kodierenden Nukleinsäure transfi ziert werden, und wobei ferner, wenn das Protein in den Zellen exprimiert wird, das Protein dazu dient, die Behandlung von einer Krankheit, einer Funktionsstörung oder einem Zustand des zentralen Nervensystems zu bewirken.

21. Die Population gemäß Anspruch 20, wobei die isolierte Nukleinsäure ein therapeutisches Protein kodiert, das ausgewählt ist, aus der Gruppe bestehend aus einem Cytokin, einem Chemokin, einem Neurotrophin, einem anderen trophischen Protein, einem Wachstumsfaktor, einem Antikörper und einem Gliom-toxischen Protein.

22. Die Population gemäß Anspruch 21, wobei die Zellen menschliche Zellen sind.

Revendications

1. Procédé d’induction de la différenciation d’une cellule stromale de moelle isolée en une cellule neuronale, ledit procédé comprenant le transfert des cellules stromales de moelle isolées dans un milieu sans sérum contenant au moins un anti-oxydant, induisant ainsi la différenciation de ladite cellule stromale de moelle isolée en une cellule neuronale.

2. Procédé selon la revendication 1, dans lequel ladite cellule stromale de moelle isolée est une cellule humaine.

3. Procédé selon la revendication 1 ou 2, dans lequel ledit anti-oxydant est choisi dans le groupe constitué par le béta-mercaptopéthanol, le diméthylsulfoxyde, l’hydroxytoluène butylé, l’hydroxyanisole butylé, l’acide ascorbique, le diméthylfumarate et la n-acétyl-cystéine.

4. Procédé selon la revendication 3, dans lequel ledit anti-oxydant est le béta-mercaptopéthanol.

5. Procédé selon la revendication 3, dans lequel ledit anti-oxydant est le diméthylsulfoxide.

6. Procédé selon la revendication 3, dans lequel ledit anti-oxydant est le diméthylsulfoxide et l’hydroxyanisole butylé.

7. Procédé in vitro de production d’une cellule neuronale isolée, ledit procédé comprenant l’isolement d’une cellule stromale de moelle, le transfert des cellules stromales de moelle isolées dans un milieu sans sérum contenant un anti-oxydant, dans lequel ledit anti-oxydant induit la différenciation de ladite cellule stromale de moelle isolée en une cellule neuronale isolée, produisant ainsi ladite cellule neuronale isolée.

8. Utilisation d’une population de cellules isolée comprenant les cellules neuronales obtenues à partir d’un échantillon de moelle osseuse d’un donneur humain, après l’isolement des cellules stromales dudit échantillon de moelle osseuse et l’induction desdites cellules stromales pour se différencier en cellules neuronales isolées par le transfert des cellules stromales de moelle isolées dans un milieu sans sérum contenant au moins un anti-oxydant, pour préparer un médicament pour effectuer le traitement d’une
9. Utilisation selon la revendication 8, dans laquelle la-dite maladie, trouble ou état du système nerveux central est choisi dans le groupe constitué par la maladie d'Alzheimer, la maladie de Parkinson, la maladie d'Huntington, la sclérose latérale amyotrophique, une tumeur, un trauma, la démence sénile, la maladie de Tay-Sach, la maladie de Sandhoff, le syndrome d'Hurler, la maladie de Krabbe, une blessure du système nerveux central traumatique induite à la naissance, l'épilepsie, la sclérose en plaques, un trauma, une tumeur, un accident vasculaire cérébral et une blessure de la moelle épinière.

10. Utilisation selon la revendication 8, dans laquelle les-dites cellules neuronales isolées avaient été transfec-tées avec un acide nucléique isolé codant une protéine thérapeutique, dans laquelle ladite protéine est exprimée dans lesdites cellules et sert à effectuer le traitement de ladite maladie, trouble ou état.

11. Utilisation selon la revendication 10, dans laquelle ledit acide nucléique isolé code une protéine théra-peutique choisie dans le groupe constitué par une cytokine, une chimio kinase, une neurotrophine, une autre protéine trophique, un facteur de croissance, un anticorps et une protéine toxique du gliome.

12. Utilisation d’une population de cellules comprenant les cellules neuronales obtenues à partir des cellules stromales de moelle d’un patient humain, après la propagation desdites cellules stromales de moelle en culture dans des conditions qui induisent leur différenciation en cellules neuronales, induite en transférant les cellules stromales de moelle isolées dans un milieu sans sérum contenant un anti-oxydant, pour préparer un médicament pour le traitement d’un patient humain nécessitant lesdites cellules neuronales.

13. Population de cellules isolée comprenant les cellules neuronales formées par un procédé d’induction de la différenciation d’une cellule stromale de moelle isolée, ledit procédé comprenant le transfert des cellules stromales de moelle isolées dans un milieu sans sérum contenant un anti-oxydant, induisant ainsi la différenciation de ladite cellule stromale moelle isolée en ladite cellule neuronale.

15. Population de cellules isolée comprenant les cellules neuronales formées par un procédé d’induction de la différenciation d’une cellule stromale de moelle isolée, ledit procédé comprenant le transfert de cel-

16. Population selon la revendication 15, où l’acide nucléique isolé code une protéine choisie dans le groupe constitué par une cytokine, une chimio kinase, une neurotrophine, une autre protéine trophique, un facteur de croissance, un anticorps et une protéine toxique du gliome.

17. Population selon la revendication 15, dans laquelle lesdites cellules sont des cellules humaines.

18. Population de cellules isolée comprenant les cellules neuronales formées par un procédé in vitro de production d’une cellule neuronale isolée, ledit procédé comprenant l’isolement d’une cellule stromale de moelle, le transfert des cellules stromales de moelle isolées dans un milieu sans sérum contenant un anti-oxydant, où ledit anti-oxydant induit la différenciation desdites cellules stromales de moelle isolées en ladite cellule neuronale isolée, produisant ainsi ladite population isolée comprenant les cellules neuronales.

19. Population selon la revendication 18, dans laquelle lesdites cellules sont des cellules humaines.

20. Population de cellules isolée comprenant les cellules neuronales formées par un procédé in vitro de production d’une cellule neuronale isolée, ledit procédé comprenant l’isolement des cellules stromales de moelle, le transfert des cellules stromales de moelle isolées dans un milieu sans sérum contenant un anti-oxydant, où ledit anti-oxydant induit la différenciation desdites cellules stromales de moelle isolées en lesdites cellules neuronales isolées, produisant ainsi lesdites cellules neuronales isolées, où lesdites cellules neuronales sont en outre transfectées avec un acide nucléique isolé codant une protéine thérapeutique, et où en outre quand ladite protéine est exprimée dans lesdites cellules, ladite protéine sert à effectuer le traitement d’une maladie, d’un trouble ou d’un état du système nerveux central.

21. Population selon la revendication 20, dans laquelle ledit acide nucléique isolé code une protéine choisie dans le groupe constitué par une cytokine, une chimio kinase, une neurotrophine, une autre protéine tro-
phique, un facteur de croissance, un anticorps et une protéine toxique du gliome.

22. Population selon la revendication 21, dans laquelle lesdites cellules sont des cellules humaines.
