Description

Background of the Invention

[0001] The present invention relates to a connector for coaxial, twinaxial and/or twisted pair cables. The invention is especially suited for the termination of shielded cables of the type mentioned, such that controlled impedance is provided through the connector, from mating face to cable end.

[0002] A variety of connectors for terminating shielded cables are known in the art. Such connectors are typically designed for a single type of application and are not typically easily altered for use with, for example, different signal/gound configurations, or for use with different types of connection methods, e.g., soldering or welding. In addition, known connectors are typically difficult to assemble, often requiring multiple molding steps, over-molding of electrical contacts and the like, which add time and expense to the connector fabrication process. Finally, prior art connectors often do not provide adequate performance characteristics for high performance systems.

Inadequate performance characteristics include, for example, the inability to control the impedance within the connector, or to match the connector impedance with that of the system in which the connector is used.

[0003] From EP-A-0 696 085 a cable connector is known comprising a planar connector body made of insulative material, a planar plate, and a cover member. The planar plate and the cover member are arranged at opposite sides of the planar connector body. Within the planar connector body a plurality of longitudinal channels are arranged each channel adapted to receive one of a plurality of socket contacts adapted for mating with a corresponding contact pin.

[0004] Moreover, it is known in the prior art to provide a cable connector with an outer ground shield housing as disclosed for example in EP-A-0 907 221.

[0005] It is an object of the present invention to provide greater flexibility in its use and which is easy and economical to produce.

Summary of the Invention

[0006] Accordingly, the invention described herein provides an electrical connector which is easily assembled and configured for alternate uses, and which may be adjusted to provide a controlled impedance across each signal line of the connector.

[0007] Briefly, the present invention provides a connector for terminating a shielded cable and connecting the cable to regularly arranged contact pins as defined in claim 1. The dependent claims relate to individual embodiments.

[0008] A plurality of the connectors according to the invention may be stacked together and held in a stacked configuration by a retaining rod which secures to mating engagement surfaces on the connector bodies. In a stack of connectors, the cover member may be provided with a conductive portion which is electrically connected to the ground plate, where the conductive portion of the cover member is formed to extend above the top side of the connector body and make electrical connection with the ground plate of the connector stacked above. In this manner, each of the ground plates in a stack of connectors may be assured of being at the same ground potential.

Brief Description of the Drawings

[0009] The invention will be described in more detail referring to the drawing in which:

Figure 1 is an exploded perspective view of one embodiment of the cable connector described herein. Figure 2 is an enlarged perspective view of the socket contact used in the connector of Figure 1. Figures 3a and 3b are perspective views illustrating the insertion of a socket contact into the connector body. Figure 4 is a perspective view of the bottom side of the assembled connector of Figure 1. Figure 5 is a perspective view of the assembled connector without the cover member. Figure 6 is a perspective view of the assembled connector with the cover member. Figures 7a and 7b are perspective views of a stack of assembled connectors. Figures 8a and 8b are perspective views of stacked connectors engaged with a pin header. Figure 9 is an exploded perspective view of the connector showing an alternate embodiment of the cover. Figure 10 is a perspective view of the bottom side of the assembled connector of Figure 9. Figure 11 is an exploded perspective view of the connector showing another alternate embodiment of the cover.

Detailed Description of the Invention

[0010] The connector 18 of the present invention, shown in Figure 1 in an exploded view, includes a connector body 20 formed from an insulative dielectric material, a plurality of socket contacts 22, a planar conductive ground plate 24, and cover member 26. Retention rods 28 may be used when a plurality of connector bodies are stacked together. The connector 18 is shown in Figure 1 in use with a pair of twinaxial cables 30. However, as will be discussed in greater detail below, the connector 18 of the present invention may be used with other types of shielded cables, such as coaxial or twisted-pair cables.

[0011] Connector body 20 includes a top side 32 and an opposing bottom side 34. The top and bottom sides...
32, 34 are defined by a front edge 36, a back edge 38 and two longitudinal side edges 40. Top side 32 of connector body 20 includes a plurality of channels 42 separated by ribs 45 extending from openings 43 in front edge 36 toward back edge 38. The channels 42 are adapted to receive socket contacts 22 and retain socket contacts 22 securely within the connector body 20.

As best seen in Figure 2, socket contact 22 includes resilient contact portions 44 which are adapted to engage a corresponding contact pin (not shown) inserted through opening 43 when the connector 18 is in use. Shank 46 extends from resilient contact portions 44 to socket terminal 48. The width and height of shank 46 and terminal 48 may be selected to control the characteristic impedance in a known microstrip relationship with the ground plane provided by ground plate 24 described in greater detail below. The characteristic impedance may also be controlled by altering the thickness of the portion of connector body 20 which is between contacts 22 and ground plate 24, or by altering the dielectric constant of the material of connector body 20.

Socket contact 22 also includes spring member 50 which locates socket contact 22 properly within channel 42, and removably retains contact 22 within its respective channel 42 without damage to the housing, such that an individual socket contact 22 may be replaced without damaging the housing. Although socket contact 22 may be provided with additional contact retention features 52 which are shaped to frictionally engage the connector body 20 and aid in maintaining the position of socket contact 22, such lance or sawtooth features may make replacement of contacts difficult. It is advantageous to have removable socket contacts 22, so that damaged contacts may be replaced at relatively low cost, instead of causing the entire connector 18 to be rendered inoperable.

As can best be seen in Figures 3a and 3b, socket contact 22 is adapted to slide longitudinally into a mating channel 42 in connector body 20. As contact 22 slides into position, socket terminal 48 engages recesses 54 in the walls of channel 42. In this manner, socket contact 22 is held securely against the bottom of channel 42, thereby eliminating air gaps between socket contact and connector body 20 which may cause impedance variations across the connector. This is important, as the spring force of the signal conductors 74 of cables 30 may otherwise tend to lift terminals 48 away from connector body 20. As socket contact 22 is moved further toward front edge 36 of connector body 20, spring member 50 snaps into detent 56 in the wall of channel 42. At this point, socket contact 22 is properly located and secured within its channel 42. Socket contact 22 is prevented from moving out of channel 42 by spring member 50 which is engaged with detent 56, and by terminal 48, which is engaged with recesses 54. A contact 22 is placed in each channel 42 in the above-described manner.

[0015] After socket contacts 22 are positioned within connector body 20, ground plate 24 may be attached to the bottom side 34 of connector body 20. Ground plate 24 is formed of a conductive material, such as metal. Ground plate 24 includes deformable grounding contacts 60 which may be selectively deformed to ground one or more of socket contacts 22. One or more of the grounding contacts 60 may be deformed so as to ground a socket contact 22. In this manner, connector 18 may be provided with a programmable grounding scheme.

[0016] Grounding contacts 60 make mechanical and electrical connection with socket contacts 22 through openings 62 in the bottom side 34 of connector body 20 (best seen in Figure 3b). The grounding contacts 60 may make only spring force contact with socket contacts 22, or they may alternatively be soldered or welded to socket contacts 22.

[0017] Ground plate 24 is secured to the bottom side 34 of connector body 20 by locking tabs 64. Locking tabs 64 engage slots 66 in the bottom side 34 of connector body 20 (Figure 4). After locking tabs 64 are positioned in slots 66, ground plate 24 is moved toward back edge 38 of connector body 20. This sliding motion causes locking tabs 64 to engage ledges (not shown) in slots 66 and pull grounding plate 24 tightly against the bottom side 34 of connector body 20. Locking tabs 64 are shaped so as to cause a camming action as ground plate 24 is moved toward back edge 38. This camming action urges the ground plate against the connector body 20, thereby eliminating air gaps, which may cause impedance variations across the connector. For this reason, it is preferred that the material of ground plate 24 be somewhat resilient. Beryllium-copper alloy is an example of one suitable material, although other suitable materials will readily be recognized by those skilled in the art. To further assure a tight fit between ground plate 24 and bottom side 34, ground plate 24 is preferably formed so as to have a slightly concave shape when unattached to connector body 20, such that locking tabs 64 tend to pull the edges of ground plate 24 toward bottom side 34 and thereby flatten ground plate 24 against bottom side 34. When ground plate 24 is fully in position, a raised projection 70 on bottom side 34 engages opening 72 in ground plate 24. In this manner, ground plate 24 is prevented from moving toward front edge 36 and possibly becoming disengaged from connector body 20.

[0018] The direction in which ground plate 24 is installed onto connector body 20 (i.e., in the direction of axial pullout when connector 18 is engaged) assures ground plate 24 will not be dislodged while disconnecting an engaged connector 18. Specifically, when cables 30 are attached to connector 18, the cable shields 73 are attached to ground plate 24 by soldering or other means such as welding. Because ground plate 24 is installed in the direction of axial pullout force (which is applied to the cable when the connector 18 is disengaged from use), pulling on the cables tends to further secure ground plate 24 to connector body 20, rather than tend-
As can be seen in Figure 4, ground plate 24 extends across each of the socket contacts 22 in the connector. This provides several advantages to the performance of connector 18. Because ground plate 24 is part of the current return path, it is advantageous to provide a wide return path as possible to minimize the self-inductance generated in the connector. A long and narrow return path tends to cause greater self-inductance, which is detrimental to the connector performance. It will be noted that the deformable ground contacts 60 of ground plate 24 are positioned such that the base of the deformed contact 60 is positioned close to front edge 36 of the connector. Because the ground plate 24 becomes part of the current return circuit of the connector, and any difference in the lengths of the signal and ground paths causes increased self-inductance in the connector (and hence an increase in impedance), it is advantageous to position the grounding contacts 60 as close as possible to the engagement point of the mating ground component, e.g., the ground pin of the mating pin header 106. In an alternate embodiment, the ground contact 60 could be shaped so as to make contact with the ground pin of the mating pin header. In this manner, the lengths of the signal and ground paths are kept as close as possible to the same length, thereby minimizing any self-inductance within the connector.

Finally, by extending ground plate 24 across each of the contacts 22, a ground plane is established across the entire connector which allows the impedance of the connector to be closely controlled at each signal line. By securing ground plate 24 in the manner described above, it is ensured that the spacing between socket contacts 22 and the ground plane created by ground plate 24 is maintained at a constant and uniform distance. Socket contacts 22 form what is referred to as a microstrip geometry with the ground plane. The method for determining the impedance of a device having microstrip geometry is known in the art, and it will be recognized that by maintaining the spacing between the ground plane and socket contacts 22 at a uniform distance, the impedance of connector 18 can be closely controlled and adjusted for optimal connector performance. For example, the impedance can be adjusted by altering the width and thickness of the socket contact, by varying the dielectric constant of the material forming connector body 20, or by altering the thickness of the material between contacts 22 and ground plate 24. If the spacing between socket contacts 22 and the ground plane varies across the width of connector 18, each of the socket contacts 22 will experience a different impedance, thus causing degradation of a signal passing through the connector. Such impedance variations limit the bandwidth of the connector and are not acceptable in many high performance systems.

After the ground plate 24 is attached to connector body 20, cables 30 may be attached to the connector 18. The signal conductors 74 of cables 30 are connected to the terminals 48 of the appropriate socket contacts 22, while the cable shields 73 are attached to ground plate 24. This may be seen in Figures 4 and 5. In Figure 5, it can be seen that the locking tab 64 may also function as a solder tab for the connection of cable shield 73. Although the signal conductors 74 of cables 30 will typically be attached to terminals 48 by soldering, other methods of connection may be used. For example, it may be desired in some instances to weld the signal conductors 74 to the socket terminals 48. For this reason, connector body 20 is provided with access openings 78 (best seen in Figure 3b). Access openings 78 allow both sides of socket terminal 48 to be reached by electrodes so that the signal conductors 30 may be welded to the terminals 48. Of course, such welding would have to occur prior to installation of ground plate 24, as ground plate 24 covers access openings 78 after ground plate 24 has been installed onto connector body 20. Alternately, access holes could also be provided in ground plate 24 for access to terminals 48. Ground plate 24 also includes several access openings 80 near back edge 38. Access openings 80, for example, allow a solder paste to be used to connect the electrical shields 73 of cables 30 to ground plate 24. Ground plate 24 may also be provided with raised ridges 82 which aid in positioning signal conductor 74 at the proper height for connection to terminals 48.

It will be noted that ribs 45 which separate channels 42 function as cable organizers, helping direct cables 30 into channels 42 and properly position cable signal conductors 74 over terminals 48. As best seen in Figure 5, ribs 45 extend only so far toward back edge 38 as is necessary to properly align signal conductors 74. This allows signal conductors 74 to be more easily routed to any of a variety of contact terminals 48 without requiring significant bending of signal conductors 74.

After cables 30 have been secured to contacts 22 and ground plate 24, cover member 26 may be installed to finish assembling connector 18. Cover member 26, as best seen in Figure 1, is secured to connector body 20 by sliding the cover member 26 from the back edge 38 toward the front edge 36 of the connector body 20. As cover member 26 slides into position, guide rails 84 on cover 26 engage slots 86 in connector body 20 to properly position and secure cover member 26. As cover member 26 becomes fully engaged with connector body 20, latching features 88 on rails 84 securely engage detents 90 within connector body 20, while lip 92 at the front edge of cover member 26 is secured under edge 94 of connector body 20. The assembled connector 18 as thus described and shown in Figure 6 is then ready for use.

In most applications, a plurality of assembled connectors 18 will be joined together for use as a "stacked" connector. An example of a set of stacked connectors is shown in Figures 7a and 7b. As seen in the Figures, the connectors are secured to each other by retention rod 28. Retention rod 28 is adapted to en-
gage a mating recess 100 on side edges 40 of connector body 20. Recesses 100 include a projecting rib 102 for engaging a mating groove 104 in retention rod 28. The grooves 104 are spaced along retention rod 28 such that when a plurality of connectors 18 are stacked together and secured by retention rod 28, the connectors 18 are held securely against one another. It is preferred that the material of retention rod 28 be somewhat resilient so that retention rod 28 may provide a compression force between the stacked connectors 18. However, the material of retention rod must also be rigid enough to maintain the stacked connectors in proper alignment in all other dimensions.

[0025] Retention rod 28 is preferably formed of a polymeric material having a durometer less than the durometer of the material forming connector body 20. In this manner, retention rod 28 will yield to the material of connector body 20 as retention rod 28 engages connector body 20. Alternately, retention rod 28 is may be formed of a material having a durometer greater than the durometer of the material forming connector body 20, such that the material of connector body 20 yields to the material of retention rod 28.

[0026] A set of stacked connectors may be engaged with a mating pin header 106, as shown in Figures 8a and 8b. It will be recognized by those skilled in the art that the configuration of retention rods 28 and recesses 100 may be altered to a variety of shapes while still performing their intended function. For example, rather than providing recess 100 in connector body 20 for receiving retention rod 28, a projection (not shown) could extend from connector body 20 and retention rod 28 could be adapted to engage the projection.

[0027] The connector 18 and stacking method described herein make it possible to interchange a single connector 18 in a series of stacked connectors without disconnecting the entire stack of connectors from the pin header 106 of a powered system. Commonly referred to as "hot swapping", this may be accomplished by simply removing the retention rods 28 from recesses 100 in the stacked connectors and pulling a single connector 18 from the pin header 106. The removed connector 18 may then be re-inserted after any necessary adjustment is made, or a new connector may be installed in its place. The retention rods 28 are then reinstalled to secure the stack of connectors. This is a significant advantage over prior art stackable connectors which required that the entire stack of connectors 18 be removed from the pin header, and often further required that the entire stack of connectors be disassembled so that a single connector could be replaced. In addition, the manner in which ground plate 24 is installed, as described above, allows a single connector 18 to be removed by pulling on cables 30 without the possibility that ground plate 24 could be dislodged from connector body 20.

[0028] To facilitate alignment of connector 18 with the pin field of pin header 106, connector body 20 may be provided with an optional guide rail 108, which is useful for guiding the assembled connector 18 into pin header 106. Guide rail 108 is adapted to mate with grooves 110 in pin header 106. The position and shape of guide rails 108 and grooves 110 may vary depending upon the particular use or application of connector 18. Further, guide rails 108 may function as a connector polarization key to prevent an improper connection with pin header 106.

[0029] Other features may be provided to connector 18 and pin header 106. For example, as seen in Figure 8b, pin header 106 may be provided with a retaining latch 112 for securing a stack of connectors 18 within pin header 106. Latch 112 is designed to engage lip 114 at the back edge 38 of connector body 20.

[0030] Although the connector has been described above for use with two twinaxial type cables, other numbers and types of cables, such as coaxial cables or twisted pair cables may be used with the connector. The identical connector body 20 in ground plate 24 may be used with different types or numbers of cables. However, a slightly modified cover member 26 may be desired for different numbers or types of cables. For example, Figures 9 and 10 illustrate use of three coaxial cables 30' with the connector body 20, contacts 22 and ground plate 24 described above. A slightly modified cover member 26' is provided to accommodate the slightly different size and shape of the coaxial cables 30'. However, the guide rails 84, latching mechanism 88 and lip 92 of cover member 26' are identical to that described above for cover member 26.

[0031] In some instances, it may be desired to form cover 26 from a conductive material or to provide cover 26 with a conductive section, such as by metal plating portions of cover 26, and to then electrically connect the conductive portion of cover 26 to ground plate 24. Such a modified connector 18'' and cover 26'' are shown in Figure 11. Cover 26'' is provided with a spring contact 116 which will make electrical contact with the ground plate 24 of a connector which is stacked above the cover 26''. Cover 26'' may make electrical contact with ground plate 24 of the connector 18'' by, for example, extending locking tabs 64 of ground plate 24 through connector body 20 to make contact with cover 26''. By electrically connecting cover 26'' with ground plate 24, the connector 18'' is provided with additional shielding and it is possible to assure each individual connector in a stack of connectors 18'' is at the same ground potential.

[0032] The invention as described above provides numerous advantages compared to prior art connectors. The programmable grounding contacts 60 in ground plate 24 allow complete flexibility as to the arrangement of signal and ground contacts, without requiring design changes to the connector body or cover member. The wide ground plate 24 provides a low impedance current return path, and the uniform spacing between socket contacts 22 and the ground plane created by ground plate 24 allows the connector impedance to be controlled in a known microstrip relationship with the ground.
plane provided by ground plate 24. The simplified stacking features allow any number of connectors 18 to stacked without extra components, while allowing the stack of connectors 18 to be easily disassembled and further allowing "hot swapping" of a single connector in a stack of connectors.

[0033] Although the present invention has been described herein with respect to certain illustrated embodiments, the intention is to cover all modifications, alternative constructions, and equivalents falling within the scope of the invention.

Claims

1. An electrical connector (18) for terminating a shielded cable (30) and connecting the cable to regularly arranged contact pins, the connector comprising:

- a planar connector body (20) formed from an insulative material, the connector body having a top surface (32) and an opposing bottom surface (34), the top and bottom surfaces defined by a front edge (36), a back edge (38) and two longitudinal side edges (40), the top surface (32) including a plurality of longitudinal channels (42), each channel adapted to receive one of a plurality of socket contacts (22) adapted for mating with a corresponding contact pin, the front edge (36) of the connector body (20) having a plurality of openings (43) for guiding the contact pins into the socket contacts (22) positioned within the channels (42),

- a planar plate (24) adapted to engage the bottom surface (34) of the connector body, the plate (24) extending across each of the plurality of socket contacts (22) to establish a plane equidistant from each of the plurality of socket contacts, and

- a cover member (26) adapted to mate with the top surface (32) of the connector body (20) and endose the longitudinal channels (42) and socket contacts (22),

characterized in that

- the planar plate (24) is a conductive ground plate (24), and

- the ground plate (24) includes at least one grounding tab (60) positioned on the ground plate (24) such that the at least one grounding tab (60) passes through an opening (62) on the bottom surface (34) of the connector body (20) to contact one of the socket contacts (22).

2. The electrical connector (18) of claim 1, wherein the ground plate (24) slidably engages the connector body (20) in a front to back direction.

3. The electrical connector (18) of claim 1 or 2, wherein the ground plate (24) further comprises at least one locking tab (64) for engaging the connector body (20), the at least one locking tab (64) adapted to urge the ground plate (24) against the bottom surface (34) of the connector body (20).

4. The electrical connector (18) of claim 3, further comprising four locking tabs (64).

5. The electrical connector (18) of claim 3 or 4, wherein the at least one locking tab (64) is adapted to make electrical contact with the shield (73) of the cable (30).

6. The electrical connector (18) of claim 1 to 5, wherein the socket contacts (22) are removably retained within the connector body (20).

7. The electrical connector (18) of claim 6, wherein the socket contacts (22) each include a spring member (50) for engaging a recess (56) in a wall of their respective channels (42) and thereby retaining the socket contacts (22) in their respective longitudinal channels (42).

8. The electrical connector (18) of any one of claims 1 to 7, further comprising a guide rail (108) extending along at least one longitudinal side edge (40).

9. The electrical connector (18) of any one of claims 1 to 7, further comprising an engagement surface (100) on at least one of its longitudinal edges (40), the engagement surface (100) adapted to mate with a retaining rod (28).

10. The electrical connector (18) of claim 9, further comprising a plurality of electrical connectors (18) forming a stack of electrical connectors, the engagement surface (100) of each of said plurality of connectors (18) aligned for engagement with the retaining rod (28).

11. The electrical connector (18) of any one of claims 1 to 10, wherein the cover member (26) further comprises a conductive portion (116) which is electrically connected to the ground plate (24), and wherein the conductive portion (116) of the cover member (26) is formed to extend above the top side (34) of the connector body (20).

Patentansprüche

1. Elektrischer Verbinder (18) zum Abschluß eines geschirmten Kabels (30) und zur Verbindung des Kabels mit regelmäßig angeordneten Kontaktstiften, wobei der Verbinder folgendes aufweist:
- einen aus einem Isoliermaterial geformten planaren Verbinderkörper (20), wobei der Verbinderkörper eine obere Fläche (32) und eine gegenüberliegende untere Fläche (34) besitzt, wobei die obere und die untere Fläche durch eine vordere Kante (36), eine hintere Kante (38) und zwei längliche Seitenkanten (40) definiert sind, wobei die obere Fläche (32) eine Mehrzahl von länglichen Kanälen (42) aufweist, wobei jeder Kanal so ausgeführt ist, daß er einen von einer Mehrzahl von Buchsenkontakten (22), die passend zu einem entsprechenden Kontaktstift ausgeführt sind, aufnehmen kann, wobei die vordere Kante (36) des Verbinderkörpers (20) eine Mehrzahl von Öffnungen (43) aufweist, um die Kontaktstifte in die innerhalb der Kanäle (42) positionierten Buchsenkontakte (22) zu führen,
- eine planare Platte (24), die so ausgeführt ist, daß sie mit der unteren Fläche (34) des Verbinderkörpers zusammengreift, wobei sich die Platte (24) über jeden der Mehrzahl von Buchsenkontakten (22) erstreckt, um eine Ebene zu schaffen, die einen gleichen Abstand von jedem der Mehrzahl von Buchsenkontakten aufweist, und
- ein Abdeckungselement (26), das passend zur oberen Fläche (32) des Verbinderkörpers (20) ausgeführt ist sowie die länglichen Kanäle (42) und die Buchsenkontakte (22) umschließt,
dadurch gekennzeichnet, daß

- die planare Platte (24) eine leitfähige Erdungsplatte (24) ist und
- die Erdungsplatte (24) mindestens einen Erdungsansatz (60) aufweist, der derart an der Erdungsplatte (24) positioniert ist, daß der mindestens eine Erdungsansatz (60) durch eine Öffnung (62) an der unteren Fläche (34) des Verbinderkörpers (20) verläuft, um einen der Buchsenkontakte (22) zu berühren.

2. Elektrischer Verbinder (18) nach Anspruch 1, bei dem die Erdungsplatte (24) in einer von vorne nach hinten verlaufenden Richtung gleitend mit dem Verbinderkörper (20) zusammengreift.

3. Elektrischer Verbinder (18) nach Anspruch 1 oder 2, bei dem die Erdungsplatte (24) weiterhin mindestens einen Verriegelungsansatz (64) zum Eingriff in den Verbinderkörper (20) aufweist, wobei der mindestens eine Verriegelungsansatz (64) so ausgeführt ist, daß er die Erdungsplatte (24) gegen die untere Fläche (34) des Verbinderkörpers (20) drückt.

4. Elektrischer Verbinder (18) nach Anspruch 3, der weiterhin vier Verriegelungsansätze (64) aufweist.

5. Elektrischer Verbinder (18) nach Anspruch 3 oder 4, bei dem der mindestens eine Verriegelungsansatz (64) so ausgeführt ist, daß er einen elektrischen Kontakt mit der Abschirmung (73) des Kabels (30) herstellt.

6. Elektrischer Verbinder (18) nach einem der Ansprüche 1 bis 5, bei dem die Buchsenkontakte (22) entferbar innerhalb des Verbinderkörpers (20) festgehalten werden.

7. Elektrischer Verbinder (18) nach Anspruch 6, bei dem die Buchsenkontakte (22) jeweils ein Federelement (50) zum Eingriff in einen Rücksprung (56) in einer Wand ihrer jeweiligen Kanäle (42) aufweisen und dadurch die Buchsenkontakte (22) in ihren jeweiligen länglichen Kanälen (42) festhalten.

8. Elektrischer Verbinder (18) nach einem der Ansprüche 1 bis 7, der weiterhin eine Führungsschiene (108) aufweist, die sich entlang mindestens einer länglichen Seitenkante (40) erstreckt.

9. Elektrischer Verbinder (18) nach einem der Ansprüche 1 bis 8, der weiterhin eine Eingriffsoberfläche (100) an mindestens einer seiner länglichen Kanten (40) aufweist, wobei die Eingriffsoberfläche (100) zum passenden Zusammengriff mit einem länglichen Verriegelungselement (28) ausgerichtet ist.

10. Elektrischer Verbinder (18) nach Anspruch 9, der weiterhin eine Mehrzahl von elektrischen Verbindern (18), die einen Stapel elektrischer Verbinder bilden, aufweist, wobei die Eingriffsoberfläche (100) eines jeden der Mehrzahl von Verbindern (18) für einen Eingriff mit dem länglichen Verriegelungselement (28) ausgerichtet ist.

11. Elektrischer Verbinder (18) nach einem der Ansprüche 1 bis 10, bei dem das Abdeckungselement (26) weiterhin einen leitfähigen Abschnitt (116) aufweist, der mit der Erdungsplatte (24) elektrisch verbunden ist, und bei dem der leitfähige Abschnitt (116) des Abdeckungselementes (26) so geformt ist, daß er sich oberhalb der oberen Seite (34) des Verbinderkörpers (20) erstreckt.

Revendications

1. Connecteur électrique (18) pour terminer un câble blindé (30) et connecter le câble à des broches de contact arrangées régulièrement, le connecteur comprenant:

- un corps de connecteur plan (20) constitué
d'une matière isolante, le corps de connecteur présentant une surface supérieure (32) et une surface inférieure opposée (34), les surfaces supérieure et inférieure étant définies par un bord avant (36), un bord arrière (38) et deux bords latéraux longitudinaux (40), la surface supérieure (32) comportant une pluralité de canaux longitudinaux (42), chaque canal étant apte à recevoir un parmi une pluralité de contacts femelles (22) aptes à être couplés à une broche de contact correspondante, le bord avant (36) du corps de connecteur (20) comportant une pluralité d’ouvertures (43) pour guider les broches de contact dans les contacts femelles (22) positionnés à l’intérieur des canaux (42),

- une plaque plane (24) apte à engager la surface inférieure (34) du corps de connecteur, la plaque (24) s’étendant à travers chacun de la pluralité de contacts femelles (22) afin d’établir un plan équidistant de chacun de la pluralité de contacts femelles, et

- un élément de couvercle (26) pouvant être adapté sur la surface supérieure (32) du corps de connecteur (20) et enfermant les canaux longitudinaux (42) et les contacts femelles (22),

caractérisé en ce que:

- la plaque plane (24) est une plaque de terre conductrice (24), et

- la plaque de terre (24) comprend au moins une lamelle plate de mise à la terre (60) positionnée sur la plaque de terre (24) de telle sorte que la au moins une lamelle plate de mise à la terre (60) passe à travers une ouverture (62) sur la surface inférieure (34) du corps de connecteur (20) pour entrer en contact avec un des contacts femelles (22).

2. Connecteur électrique (18) selon la revendication 1, dans lequel la plaque de terre (24) engage d’une façon coulissante le corps de connecteur (20) dans une direction allant d’avant en arrière.

3. Connecteur électrique (18) selon la revendication 1 ou 2, dans lequel la plaque de terre (24) comprend en outre au moins une patte de verrouillage (64) pour engager le corps de connecteur (20), la au moins une patte de verrouillage (64) étant apte à pousser la plaque de terre (24) contre la surface inférieure (34) du corps de connecteur (20).

4. Connecteur électrique (18) selon la revendication 3, comprenant en outre quatre pattes de verrouillage (64).

5. Connecteur électrique (18) selon la revendication 3 ou 4, dans lequel la au moins une patte de verrouillage (64) est apte à faire un contact électrique avec le blindage (73) du câble (30).

6. Connecteur électrique (18) selon l’une quelconque des revendications 1 à 5, dans lequel les contacts femelles (22) sont retenus d’une façon amovible à l’intérieur du corps de connecteur (20).

7. Connecteur électrique (18) selon la revendication 6, dans lequel les contacts femelles (22) comprennent chacun un élément de ressort (50) pour engager un évidement (56) dans une paroi de leurs canaux respectifs (42), et retenant de ce fait les contacts femelles (22) dans leurs canaux longitudinaux respectifs (42).

8. Connecteur électrique (18) selon l’une quelconque des revendications 1 à 7, comprenant en outre un rail de guidage (108) s’étendant le long d’au moins un bord latéral longitudinal (40).

9. Connecteur électrique (18) selon l’une quelconque des revendications 1 à 7, comprenant en outre une surface de prise (100) sur au moins un de ses bords longitudinaux (40), la surface de prise (100) étant apte à se coupler avec une tige de retenue (28).

10. Connecteur électrique (18) selon la revendication 9, comprenant en outre une pluralité de connecteurs électriques (18), formant une pile de connecteurs électriques, la surface de prise (100) de chacun de ladite pluralité de connecteurs (18) étant alignée pour s’engager avec la tige de retenue (28).

11. Connecteur électrique (18) selon l’une quelconque des revendications 1 à 10, dans lequel l’élément de couvercle (26) comprend en outre une partie conductrice (116) qui est électriquement connectée à la plaque de terre (24), et dans lequel la partie conductrice (116) de l’élément de couvercle (26) est formée de manière à s’étendre au-dessus du côté supérieur (34) du corps de connecteur (20).
