Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
The present invention relates to an apparatus and process for the formation of porous polymer particles for use in chromatography techniques.

The capacity of certain porous support particles to cause selective retardation based on either size or shape is well known. Such particles are used in chromatographic separation techniques, for example gel filtration, to separate biological macromolecules, e.g. proteins, DNA, RNA polysaccharides and the like. The sieving particles are characterized by the presence of a microporous structure that exerts a selective action on the migrating solute macromolecules, restricting passage of larger particles more than that of the smaller particles. Thus, the utility of sieving lies in the capacity of the particles to distinguish between molecules of different sizes and shapes.

Affinity chromatography is a chromatographic method used for the isolation of proteins and other biological compounds. This technique is performed using an affinity ligand attached to a support particle and the resulting adsorbent packed into a chromatography column. The target protein is captured from solution by selective binding to the immobilized ligand. The bound protein may be washed to remove unwanted contaminants and subsequently eluted in a highly purified form.

The particle size distribution produced by known apparatus and methods require further sorting steps or procedures in order to select particles of uniform size required for chromatography. The additional sorting steps introduce further costs that could be avoided if the factors determining size distribution of the particles and operating variables are closely controlled. Without additional sorting steps, the products manufactured by conventional rotary atomization or emulsion techniques cannot be used in applications where the size distribution of the particles must be very narrow. For example, when using particles in blood purification applications, small particles must be avoided as small particles could be caught by the carrier fluid and would result in contamination of the purified material. Of course a narrow particle size distribution improves performances of particles in many applications, including chromatographic applications.

Operating variables that influence droplet size produced from atomizer wheels and hence particle size include speed of rotation, wheel diameter, wheel design, feed rate, viscosity of feed and air, density of feed and air and surface tension of feed.

The atmosphere within which a particle passes is important in order to avoid reduction of pore size. In particular, humidity and temperature control avoids particle desiccation during polymerization and gelling stages. Particle desiccation reduces pore size. It is desirable to have a machine and process to produce particles using centrifugal action in such a manner as that the particles have a narrow particle size distribution with both high porosity and flow.

Lengthy consideration of prior art devices and processes has identified a number of factors that may be responsible for the wide size distribution of particles. Such factors include interruptions on the wheel surface that may impede radial acceleration of the particle solution and adhesion to the surface of the wheel; lack of adequate temperature control on the atomizer wheel that may result in changes in feed viscosity and particle structure; and uncontrolled airflow.
patterns at the perimeter of the atomizer wheel that may result in particle twinning due to collisions between particles prior to gelation and in undesired drying of the particles due to a modification in their path down from the wheel to the collecting liquid.

Summary of the Invention:

[0010] It has now been recognized that control of humidity and temperature within specific parameters in the immediate area of the atomizer wheel will yield particles of a narrower size distribution than previously possible with both good porosity and rigidity.

[0011] Specifically, it has been discovered that the air flow rate, temperature and humidity may be controlled in the immediate area of the atomizer wheel with sufficient accuracy to produce particles of a narrow size distribution. Control of temperature and humidity is achieved by the combination of temperature and humidity control means and an enclosure comprising an aperture, thus partially enclosing the atomizer machine.

[0012] According to the present invention, an atomizer machine which can be used for the production of porous particles of a polymer such as agarose, comprises an atomizer wheel rotatable about an axis, a distributor for depositing polymer in fluid state to said wheel, a catch tray disposed under the atomizer wheel, to collect polymer particles formed as a result of ejection of the polymer from the wheel’s edge as the atomizer wheel rotates, an enclosure, enclosing said atomizer wheel, said distributor and said catch tray, said enclosure defining a partition between interior and exterior environments of said atomizer machine, an aperture on said enclosure, allowing gas exchange between the interior and exterior environments, and means for controlling temperature and humidity in the interior environment.

[0013] A method of the invention, for producing porous particles of a polymer such as agarose, comprises supplying polymer to a machine of the invention, and allowing gas exchange through the aperture, thereby regulating temperature, humidity and air flow within the interior environment.

[0014] In an embodiment, the aperture is of variable size.

[0015] In an embodiment, the enclosure includes a peripheral wall surrounding the atomizer wheel, the distributor and the catch tray and a roof portion covering the peripheral wall.

[0016] In an embodiment, the above-mentioned peripheral wall is generally circular.

[0017] In an embodiment, the above-mentioned aperture extends circumferentially along the peripheral wall.

[0018] In an embodiment, the above-mentioned peripheral wall includes an upper portion and a lower portion, the aperture being defined between the upper portion and between the lower portion.

[0019] In an embodiment, the above-mentioned atomizer machine further comprises an actuator to displace the upper portion and the lower portion with relation to one another to vary the size of the aperture.

[0020] In an embodiment, the above-mentioned actuator is operative to displace the upper portion along the axis to vary the size of the aperture.

[0021] In an embodiment, the means for controlling temperature and humidity comprises at least one of: a unit for controlling a size of the aperture, a unit for controlling a level of temperature of the distributor and wheel, a unit for controlling a level of temperature and a flow rate of water in the catch tray, at least one valve providing at least one respective vapor stream at a periphery of the atomizer wheel, over the wheel and in the enclosure, and at least one steam trap for de-misting the air in the interior environment and preventing water droplets from falling on the atomizer wheel.

[0022] In an embodiment, the above-mentioned atomizer machine further comprises a monitor capable of indicating a level of temperature in the interior environment.

[0023] In an embodiment, the above-mentioned atomizer machine further comprises a monitor capable of indicating a level of humidity in the interior environment.

[0024] In an embodiment, the above-mentioned atomizer machine further comprises a trajectory control means to control a trajectory of the particles from a periphery of the atomizer wheel to the catch tray.

[0025] In an embodiment, the above-mentioned trajectory control means comprises a unit for controlling a size of the aperture, disposing steam valves at the periphery of the atomizer wheel, over the atomizer wheel and directly into the enclosure, and controlling airflow patterns at the periphery of the atomizer wheel.

[0026] In an embodiment, the above-mentioned atomizer machine further comprises a reactor for producing the polymer and at least one temperature controlled conduit for feeding the polymer to the distributor.

[0027] In an embodiment, the above-mentioned at least one conduit consists of a double jacket tube defining an inner passage for feeding the polymer to the distributor and an outer envelope surrounding the inner passage, through which outer envelope a temperature liquid is flowed to control a level of temperature of the polymer.

[0028] In an embodiment, the above-mentioned distributor rotates in the same direction as the atomizer wheel.

[0029] In an embodiment, the above-mentioned distributor comprises a plurality of holes.

[0030] In an embodiment, the above-mentioned plurality of holes are disposed in a circle.

[0031] In an embodiment, the above-mentioned distributor has 24 holes.
In an embodiment, the above-mentioned atomizer wheel has a flat surface.

In an embodiment, the above-mentioned atomizer machine further comprises a shaft for receiving the atomizer wheel, the shaft being conical and tapered so as to reduce vibrations during rotation of the atomizer wheel.

In an embodiment, the above-mentioned atomizer machine further comprises a shaft for receiving the atomizer wheel, the shaft having a threaded section for securing the atomizer wheel to the shaft.

In an embodiment, the above-mentioned atomizer machine further comprises a sorting bin for receiving and sorting the particles from the catch tray.

In an embodiment, the above-mentioned atomizer wheel has a perimeter, the perimeter having radially projecting teeth.

In an embodiment, the above-mentioned atomizer machine further comprises at least one baffle disposed within the enclosure for regulating air flow within the internal environment.

In an embodiment, the above-mentioned at least one baffle is a plurality of baffles.

In an embodiment, the above-mentioned plurality of baffles is 4 baffles.

In an embodiment, the above-mentioned method further comprises varying a size of the aperture to vary a rate of gaseous exchange.

In a further embodiment, the above mentioned enclosure comprises a dome. The dome partially enclosing the atomizer machine at once creates an open-system and creates a zone surrounding the machine. The open system is necessary to obtain an air flow current from within the zone to the exterior of the zone. The air flow current contributes to the control of temperature and humidity by preventing build-up of heat within the immediate vicinity of the wheel as a result of rapid rotation of the wheel. The creation of a zone surrounding the machine is necessary to define an area within which a desired temperature and humidity profile may be maintained. It has been found that accurate control of the factors that determine the temperature and humidity surrounding the machine is not possible in absence of a structure that defines a zone within which the temperature and humidity control means operate to maintain the desired temperature and humidity profile. Advantageously, the dome is adjustable, thus providing adjustment of the aperture size, to compensate for variations in the factors that affect the temperature and humidity in the immediate vicinity of the gel and particles.

Temperature, humidity and turbulence of the air surrounding the apparatus and inside the apparatus affect the properties of beads: porosity, flow, average particle size, particle size distribution, bead shape and non-specific binding.

In a further embodiment, the invention further provides an atomizer machine for the production of porous polymer particles having a narrow size distribution comprising:

a) an atomizer wheel rotating about an axis;
   b) a distributor for providing a uniform thin layer of a gelatinous polymer on the wheel;
   c) a shaft connecting the wheel to a rotor;
   d) a catch tray disposed under the wheel to collect the particles;
   e) a dome partially enclosing the atomizer wheel and catch tray so as to maintain an open system and defining a zone surrounding the wheel and catch tray;
   f) a means for temperature and humidity control for creating and maintaining a temperature and humidity gradient within the zone;

wherein the gelatinous polymer deposited on the rotating wheel moves to the periphery of the wheel under action of centrifugal force, the film being broken into free flying particles at the edge of the wheel.

These and other aspects of the invention shall become apparent to those of ordinary skill in the art upon consideration of the following description of specific embodiments in conjunction with the accompanying drawings.

Brief Description of the Drawings:

In the drawings:

Figure 1 illustrates an apparatus for producing porous particles according to an embodiment of the invention;

Figure 2 illustrates the central column of the apparatus of Figure 1 showing bottom and top steam diffusers and shaft-wheel-distributor assembly;

Figure 3 illustrates the shaft-wheel-distributor assembly of Figure 2;

Figure 4 is a bottom view of the bottom steam diffuser of Figure 2 that distributes steam to the edge of the wheel;
One embodiment of the liquid atomization apparatus of the invention is illustrated in Figure 1. A solution comprising a polymer is prepared in reactor (1). Solid particles are formed from the solution in a beader (2). A heated tube (12) connects the reactor (1) to the beader (2). The apparatus and method of the invention will be described in conjunction with the production of agarose beads. However, the apparatus may be used to produce particles of any other polymer.

The polymer is first slowly poured into a solvent, in an embodiment, at room temperature, under vigorous stirring in a sealed stainless steel reactor (1), yielding a mixture. Suitable solvents include, but are not limited to, water, aqueous salt solutions, and organic solvents. The mixture is heated up to over 90°C to allow a complete dissolution of the agarose, forming a solution. The solution is quickly cooled down to an intermediate temperature between dissolution and gelling temperatures, where a special additive can be added to the solution in order to improve bead porosity. This additive or chemical can be any chemical that helps obtain improved porosity, such as a salt (for example, ammonium sulfate) or a surfactant, in an embodiment, ammonium sulfate. Then, the solution is slowly cooled down to the process temperature, close enough to the gelling temperature, at a rate, for example, of up to about 0.5°C/min, in an embodiment, not more than 0.1°C/min.

Once the gel has reached its process temperature, it is pumped through a heated tube (12) maintained at the gel process temperature, from the reactor (1) to a nozzle (42), using a gear pump (11) also maintained at the gel process temperature by means of a pump head heater (not illustrated). The gel is supplied to a distributor (40) by the nozzle (42), and evenly distributed on the atomization wheel (39) by means of a distributor (40). A thin uniform layer is formed by both centrifugal force and the use of the distributor (40), and split by teeth (43) into filaments, which are broken in uniform sized spheres by the air flowing at the atomization wheel (39) edge. The beads travel through the surrounding air in the dome (13), where relative humidity and temperature are accurately controlled (from hot and humid at the atomization wheel (39) edge to less hot and less humid air at the catch tray (14) level) before they fall into the catch tray (14). The temperature and humidity profiles in the dome (13), between the atomization wheel (39) and surface of the catch tray (45), are accurately controlled in order to make sure that the bead formed turns into solid phase prior to reaching the catch tray surface. A liquid, for example water, is continuously recirculated at a flow rate in a closed loop from the catch tray (14) to a siever (20) and back to the catch tray via a recirculation pump (23). The flow rate is adjusted in such way that the surface of the catch tray (45) is always covered with a thin continuous layer of liquid. A heat exchanger (21) is installed in the inlet reservoir (22) of the recirculation pump (23) to control the catch tray (14) temperature. The beads can be collected at the outlet of the siever machine (20) in a sealed bucket (24) for packaging.

The beader (2) thus contains a dome (13) and a catch tray (14). The dome (13) is not attached to the catch tray (14), leaving the beader (2) open for air exchanges with the production room. The dome skirt (15) controls the gap between the dome (13) and the catch tray (14), which is responsible for the fresh air inlet into the process. Therefore the dome (13) defines a zone surrounding the apparatus and partially encloses the atomizer wheel in an open system. In certain embodiments, the temperature and humidity of the ambient air in the production room should be accurately controlled between 20-23°C and 25-75% humidity, respectively, in order to get an adequate temperature and humidity profile in the dome (13). Deviations from these recommended adjustments could be compensated by variations in other process parameters such as the gap between the dome (13) and the catch tray (14) as an example.

The catch tray (14), which has a slope from the center to the edge, collects the beads off the atomization wheel in a liquid that is in continuous recirculation. In order to allow the dome to move up and down for maintenance, cleaning and atomization wheel (39) installation, a system of, for example, at least one rod with an air cylinder, for example, three rods (18) with three air cylinders (19), may be used. A rigid structure (44) stabilizes the dome and avoids any instability that could result in vibration or movements of the dome (13).

Two columns are included in the beader: a top column (4), which is attached to the dome (13), and a bottom column (3), which is attached to the catch tray (14). These two columns are clearly illustrated in drawings 2 to 7. The bottom column (3) holds the atomization wheel and helps in the control of temperature and humidity profiles in the dome (39), while the top column (4) controls the environment over the atomization wheel and helps in the control of the temperature and humidity in the dome (13). For maximum advantage, these two columns should be centered at all times. Both the rods (18) and the rigid structure (44) of the dome (13) guarantee centering of the two columns (3) and (4). A main steam supply (5) is split in two steam lines (6) and (7), that are required for the control of both temperature and humidity in the dome (13).
A collecting liquid (water in the illustrated example) is distributed from the inlet reservoir (22) to the catch tray (14) through a splitter (16) which can be located at the center of the catch tray (14). The liquid forms a uniform and evenly distributed thin film on the catch tray surface (45) and ends in tubes (17) that are connected to the siever (20). For maximum advantage, the catch tray surface (45) should be continuously covered by a thin layer of liquid in order to prevent drying of the beads as they fall on the catch tray (14). The liquid flow rate in the catch tray (14) and its temperature affect the control of humidity and temperature in the dome (13).

The center part of the dome is illustrated in figure 2. A flat atomization wheel (39) that, in certain embodiments, can have radially projecting teeth (43) at an edge thereof, is covered by a distributor (40), which is centered with the atomization wheel (39) and, in certain embodiments, rotates at the same speed as the atomization wheel. A plate (58) is screwed to the tapered shaft (29), keeping the atomization wheel-distributor assembly in place. The distributor (40) is the recipient for the gel that comes out from a nozzle (42). The gel falls on a distributor lip (67), which is filled with holes (66), allowing the gel to be evenly distributed at the bottom of the distributor (40). These holes should occupy almost all the distributor lip (67) surface and be spaced in such a way that sufficient strength of the distributor (40) is maintained. An inside cylinder (60) of the distributor (40) is longer than an outside cylinder (59) giving a constant and reproducible gap between the atomization wheel (39) and the distributor (40). This design avoids the use of spacers, which would unbalance the atomization wheel-distributor assembly and increase particle size distribution. In mounting high speed rotary bodies it is advantageous that the rotating mass be balanced. A suitable mounting arrangement for securely position the wheel on the rotatable shaft is to use a tapered shaft (29) in order to make atomization wheel-shaft alignment easy and reproducible and to maintain balancing. The inside of the atomization wheel (39) is machined with the same slope as the tapered section (61) of the tapered shaft (29). In an embodiment, the atomization wheel (39) does not touch the bottom of the tapered section (61) but is supported by the tapered section (61) itself. This has been designed to avoid any screwed part that would make the alignment difficult to reproduce. For maximum advantage, the tapered shaft-atomization wheel-distributor assembly should be balanced, advantageously, at all speeds within the rotation speed range utilized, to eliminate vibration.

The atomization wheel (39) stands over a bottom steam diffuser (31), which helps the regulation of temperature and humidity in the dome (13) and in the area close to the atomization wheel (39). The bottom steam diffuser (31) is connected to a bottom steam line (7) where a steam trap (48) removes any steam condensate located in the bottom steam line (7). A needle valve (65), located as close as possible to the steam trap (48), accurately controls the steam flow rate to the bottom steam diffuser (31). Steam is distributed into the dome (13) via slots (50) located on the side of the bottom steam diffuser (31). A bottom plate (46) and a top plate (38) are part of the bottom steam diffuser (31) and can be affixed to it using screws (49), for example. A drain (47) allows the evacuation of any condensation that could occur in the bottom steam diffuser (31) and avoids water accumulation that would result in steam bubbling and result in a change in humidity and temperature conditions in the dome (13). An annular plate (30) having holes, for example, very small holes, covers the side of the bottom steam diffuser (31). The small holes of the annular plate (30) cover a limited sector of the annular plate (30). For example, the sector may be defined by the first 60° starting at the bottom of the annular plate (30), in order to guide the steam in the dome (13) and not under the atomization wheel (39) or at the atomization wheel (39) edge, close to the teeth (43). The bottom column (3) also holds a motor (not illustrated) that controls atomization wheel (39) RPMs (revolutions per minute).

The top steam diffuser (26) is connected to the top column (4) using flange (28), spacer (25) and connection (27). The spacer (25) and connection (27) avoid any chimney effect in the top column (4) that could result from the high spinning rate of the atomization wheel and thus affect the temperature and humidity conditions in the dome (13) and in the area close to and above the atomization wheel (39). The steam in the top steam line (6) goes through a demister (69) where most water drops resulting from steam condensation are removed. A steam trap (68) completes condensate removal from the top steam line (6). The top steam line (6) is then split into three steam lines (8), (9) and (10), where needle valves (62), (63) and (64) respectively, accurately control the steam flow rate in the areas of the top steam diffuser (26). The first steam line (10) is split into a group of holes (55) located immediately above the distributor (40), and keeps the air above the distributor (40) fully saturated in order to prevent the liquid sprayed from drying under the effect of the fast air flow rate generated by pumping caused by the rotation of the atomization wheel (39). The second steam line (9) is split into a second group of holes (54) forming a circle located outside the distributor (40) but still above the atomization wheel (39). This second steam line (9) is also required to avoid drying of the liquid on the atomization wheel (39) but also to maintain the required temperature profile above the atomization wheel (39). A ring (57) restricts exchanges between the dome (13) and the area above the atomization wheel (39) and helps to control temperature and humidity conditions above the atomization wheel (39). The third steam line (8) supplies steam to a group of holes (53) located above the atomization wheel (39) but outside the ring (57), directing steam in the dome (13), close to the atomization wheel (39) edge.

The combination of appropriate adjustments to the following process parameters combined with the presence of a demister (69), steam traps (48) and (68), bottom steam diffuser (31) and top steam diffuser (26) controls the temperature and humidity profiles in the dome (13), in the area above the atomization wheel and at the atomization
wheel edge: distance between the dome (13) and the catch tray (14), steam pressure, temperature and flow rate of the liquid in the catch tray, humidity and temperature of the air surrounding the apparatus (production room), needle valves (62), (63), (64), (65) adjustments, distance between the atomization wheel (39) and the ring (57) of the top steam diffuser (51), atomization wheel (39) spinning rate, distance between the atomization wheel (39) and the surface of the catch tray (45). These parameters control temperature and humidity profiles and are adjusted according to the product manufactured and desired properties.

Although various embodiments of the invention are disclosed herein, many adaptations and modifications may be made within the scope of the invention in accordance with the common general knowledge of those skilled in this art. Such modifications include the substitution of known equivalents for any aspect of the invention in order to achieve substantially the same result in substantially the same way. Numeric ranges are inclusive of the numbers defining the range. In the claims, the word "comprising" is used as an open-ended term, substantially equivalent to the phrase "including, but not limited to". The following examples are illustrative of various aspects of the invention, and do not limit the broad aspects of the invention as disclosed herein.

Examples

Particles produced by the apparatus and method of the present invention have a very narrow size distribution as illustrated by the following examples describing agarose bead manufacture. The polymer preparation steps and temperatures and most process parameters are specific to agarose preparation and could differ depending on the polymer used for particle formation.

Example 1: Preparation of 4% 100 µm agarose beads

300 g of agarose was slowly poured in 4.25L of purified water under vigorous mixing. This solution was heated up to 97-99°C for 30 minutes and cooled down to 70°C. A heating/cooling fluid was used in the jacket of the reactor to control the temperature accurately. 750 mL of a 0.75M ammonium sulfate solution, maintained at 70°C, was added very slowly and under vigorous stirring to the previous agarose solution in order to prevent local salting out, which would result in the formation of lumps. The final solution was cooled to 56-57°C at a rate not more than 0.1 °C/min. In the meantime, the beader was started for stabilization. Atomization wheel-column centering was checked, and the distance between the atomization wheel and the top column was adjusted to 15 mm. The dome opening (distance between the dome and the catch tray) was adjusted to 7 cm. The atomization wheel speed was adjusted to 4900-5100 RPM, needle valves were all adjusted at 7 and steam pressure was set at 5psig at the boiler outlet. These steam adjustments allowed the control of dome temperature at 36-39°C close to the edge of the atomization wheel and were adequate for the product manufactured and the size of the dome. Approximately 60L/minute of purified water maintained at 16-19°C were recirculated in the catch tray to ensure that the catch tray surface is continuously covered with a thin film of water. This water flow rate is also appropriated for the control of temperature and humidity in the dome. Resulting stabilized beader temperatures were the following:

- Atomization wheel temperature: 56-60°C
- Catch tray temperature: 16-19°C
- Dome temperature close to the atomization wheel edge: 37-39°C
- Temperature at area above atomization wheel: 71-73°C

Once the beader was stabilized and the gel at the right temperature, the gear pump was turned on, feeding 1.6L of gel/hr to the atomization wheel. The following properties were recorded:

Process reproducibility has been demonstrated and is clearly documented. The particle size distribution before sieving is very narrow, a lot more than any equivalent product available on the market at the moment. The distribution can be significantly improved by sieving, without significantly reducing the global yield. As an example, a 5L batch prepared as above gave reproducibly 6.5 to 6.8L of beads.

Example 2: Preparation of 4% 100 μm agarose beads using apparatus further comprising baffles

A plurality of 3 inch or 6 inch baffles were inserted into the dome in order to get a more homogeneous temperature profile in the dome. Four baffles were equally distributed on the inside of the dome, vertically, to inhibit the effect of room conditions in the dome. With the baffles in place, the dome is less sensitive to ambient conditions, and dome conditions are more easily reproduced. In addition, a wider range of particle size can be produced in the same apparatus when the baffles are used. The increase in disk RPM required to produce smaller particles affects the air pattern and hydrodynamics in the dome. The presence of baffles makes the temperature profiles less dependent on disk RPM. Also, the production of large particles (above 200 microns) resulted in projection of particles on the walls of the dome, due to the inertia of the particles produced. The presence of baffles affects the air pattern in such a way that the particles formed fall closer to the bottom column, making possible the manufacture of large particles without changing the design of the equipment.

Example 3: Preparation of 5% 200 μm agarose beads

A procedure similar to the one described for the preparation of 4% 100 μm agarose beads has been applied for the manufacturing of 200 μm agarose beads at the 2L scale. The differences are set forth in the present description.

110 g of agarose was slowly poured in 1.7L of purified water under vigorous mixing. This solution was heated up to 97-99°C for 30 minutes and cooled down to 70°C. 300 mL of a 0.75M ammonium sulfate solution, maintained at 70°C, was added very slowly and under vigorous stirring to the previous agarose solution. The final solution was cooled to 55-57°C at a rate not more than 0.1°C/min.

In the meantime, the beader was started for stabilization. The distance between the atomization wheel and the top column was adjusted to 15 mm. The dome opening was adjusted to 4 cm. The atomization wheel speed was adjusted to about 2000 RPM, needle valves were all adjusted at 3 and steam pressure was set at 5psig at the boiler outlet. These steam adjustments allowed the control of dome temperature at 47-50°C close to the edge of the atomization wheel and were adequate for the product manufactured and the size of the dome.

Approximately 60L/minute of purified water maintained at 14-16°C was recirculated in the catch tray. Resulting stabilized beader temperatures were the following:

| Atomization wheel temperature: Not available due to the dome opening |
| Catch tray temperature: 14-16°C |
| Dome temperature close to the atomization wheel edge: 47-50°C |
| Temperature at area above atomization wheel: 78-80°C |

Once the beader was stabilized and the gel at the right temperature, the gear pump was turned on, feeding about 2.8L of gel/hr to the atomization wheel. The following properties were recorded:

Example 4: Preparation of 4% 125 μm agarose beads

[0069] The procedure described for the production of 4% 100 microns agarose beads has been applied for the production of 4% 125 microns agarose beads at the 3L scale. The differences are set forth in the present description.

[0070] 180 g of agarose was slowly poured in 2.55L of purified water under vigorous mixing. This solution was heated up to 97-99°C for 30 minutes and cooled down to 70°C. 450 mL of a 0.75M ammonium sulfate solution, maintained at 70°C, was added very slowly and under vigorous stirring to the previous agarose solution. The final solution was cooled to 55-57°C at a rate not more than 0.1 °C/min.

[0071] In the meantime, the beader was started for stabilization. The distance between the atomization wheel and the top column was adjusted to 15 mm. The dome opening was adjusted to 7 cm. The atomization wheel speed was adjusted to 3700-3800 RPM, needle valves were all adjusted at 4-5 and steam pressure was set at 5psig at the boiler outlet. These steam adjustments allowed the control of dome temperature at 35-37°C close to the edge of the atomization wheel and were adequate for the product manufactured and the size of the dome. Approximately 60L/minute of purified water maintained at 14-16°C were recirculated in the catch tray. Resulting stabilized beader temperatures were the following:

- Atomization wheel temperature: 56-58°C
- Catch tray temperature: 14-16°C
- Dome temperature close to the atomization wheel edge: 35-37°C
- Temperature at area above atomization wheel: 71-75°C

[0072] Once the beader was stabilized and the gel at the right temperature, the gear pump was turned on, feeding about 1.9L of gel/hr to the atomization wheel. The following properties were recorded:

Example 5: Preparation of 4% 60 μm agarose beads

[0073] The procedure described for the production of 4% 100 microns agarose beads has been applied for the production of 4% 60 microns agarose beads at the 2L scale. The differences are set forth in the present description.

[0074] 120 g of agarose was slowly poured in 1.7L of purified water under vigorous mixing. This solution was heated up to 97-99°C for 30 minutes and cooled down to 70°C. 300 mL of a 0.75M ammonium sulfate solution, maintained at 70°C, was added very slowly and under vigorous stirring to the previous agarose solution. The final solution was cooled to 56-58°C at a rate not more than 0.1 °C/min.

[0075] In the meantime, the beader was started for stabilization. The distance between the atomization wheel and the top column was adjusted to 15 mm. The dome opening was adjusted to 7 cm. The atomization wheel speed was adjusted to 7200 RPM, needle valves were all adjusted at 7 and steam pressure was set at 5psig at the boiler outlet. Those steam adjustments allowed the control of dome temperature at 33-35°C close to the edge of the atomization wheel and were adequate for the product manufactured and the size of the dome. Approximately 60L/minute of purified water maintained at 16-19°C were recirculated in the catch tray. Resulting stabilized beader temperatures were the following:

- Atomization wheel temperature: 56-58°C
- Catch tray temperature: 16-19°C
- Dome temperature close to the atomization wheel edge: 33-35°C
- Temperature at area above atomization wheel: 68-70°C

[0076] Once the beader was stabilized and the gel at the right temperature, the gear pump was turned on, feeding about 0.6L of gel/hr to the atomization wheel. The following properties were recorded:

[0077] Again lot 001108446 was manufactured using the 6" baffles as described in the example above and compared to the standard material to demonstrate that the presence of baffles do not affect the particle properties.
Example 6: Preparation of 6% 100 μm agarose beads

[0078] The procedure described for the production of 4% 100 microns agarose beads has been applied for the production of 6% 100 microns agarose beads at the 5L scale. The differences are set forth in the present description.

[0079] 380 g of agarose was slowly poured in 4.25L of purified water under vigorous mixing. This solution was heated up to 97-99°C for 30 minutes and cooled down to 70°C. 750 mL of a 0.75M ammonium sulfate solution, maintained at 70°C, was added very slowly and under vigorous stirring to the previous agarose solution. The final solution was cooled to 59-61°C at a rate not more than 0.1 °C/min.

[0080] In the meantime, the beader was started for stabilization. The distance between the atomization wheel and the top column was adjusted to 15 mm. The dome opening was adjusted to 7 cm. The atomization wheel speed was adjusted to 4900-5100 RPM, needle valves were all adjusted at 7-9 and steam pressure was set at 5psig at the boiler outlet. Those steam adjustments allowed the control of dome temperature at 37-39°C close to the edge of the atomization wheel and were adequate for the product manufactured and the size of the dome. Approximately 60L/minute of purified water maintained at 16-20°C were recirculated in the catch tray. Resulting stabilized beader temperatures were the following:

- Atomization wheel temperature: 59-63
- Catch tray temperature: 16-20°C
- Dome temperature close to the atomization wheel edge: 37-39°C
- Temperature at area above atomization wheel: 71-74°C

[0081] Once the beader was stabilized and the gel at the right temperature, the gear pump was turned on, feeding about 1.7L of gel/hr to the atomization wheel. The following properties were recorded:

Batch 001026439 was produced using a higher pump flow rate. According to the theory, the pump flow rate could be significantly increased without affecting the product quality. This has been confirmed with lot 001026439, where the pump was increased to its limit and delivering about 3.5L/hr of gel on the atomization wheel without affecting the properties. Only the particle size distribution before sieving was slightly broader when the pump flow rate is increased, resulting in a lower product yield. Therefore the gel flow rate fed to the atomization disk is not limited to the examples above, higher and lower feed rates can result in the same product.

[0082] In an embodiment, the atomizer machine may further comprise at least one baffle, in a further embodiment, a plurality of baffles, in a further embodiment, 4 baffles, which is/are disposed within the enclosure and can affect/regulate
the air pattern in the interior environment.

[0083] The particles produced by the apparatus and process of present invention may be used in all the chromato-
graphic and electrophoretic methodologies for industrial purification purposes including affinity chromatography, gel
filtration, ion-exchange chromatography, as support for grafting different types of ligands; and coating rigid spheres of
glass or plastic for types of chromatographic applications.

Claims

1. An atomizer machine which can be used for the production of porous polymer particles, comprising:
   a. an atomizer wheel rotatable about an axis;
   b. a distributor for depositing polymer in fluid state to said wheel;
   c. a catch tray disposed under the atomizer wheel, to collect polymer particles formed as a result of ejection of
      the polymer from the wheel’s edge as the atomizer wheel rotates;
   d. an enclosure, enclosing said atomizer wheel, said distributor and said catch tray, said enclosure defining a
      partition between interior and exterior environments of said atomizer machine;
   e. an aperture on said enclosure, allowing gas exchange between the interior and exterior environments; and
   f. means for controlling temperature and humidity in the interior environment.

2. A machine according to claim 1, wherein said aperture is of variable size.

3. A machine according to claim 2, wherein said enclosure includes a peripheral wall surrounding said atomizer wheel,
said distributor and said catch tray, and a roof portion covering said peripheral wall.

4. A machine according to claim 3, wherein said peripheral wall is generally circular.

5. A machine according to claim 4, wherein said aperture extends circumferentially along said peripheral wall.

6. A machine according to claim 4 or claim 5, wherein said peripheral wall includes an upper portion and a lower
   portion, said aperture being defined between said upper portion and said lower portion.

7. A machine according to claim 6, further comprising an actuator to displace said upper portion and said lower portion
   relative to each other, to vary the size of said aperture.

8. A machine according to claim 7, wherein said actuator is operative to displace said upper portion along said axis,
to vary the size of said aperture.

9. A machine according to any preceding claim, wherein the means for controlling temperature and humidity comprises
   at least one of: a unit for controlling size of said aperture, a unit for controlling temperature of the distributor and
   wheel, a unit for controlling temperature and flow rate of water in the catch tray, at least one valve providing at least
   one respective vapor stream at said atomizer wheel’s periphery, over the wheel and in the enclosure, and at least
   one steam trap for de-misting air in said interior environment and preventing water droplets from falling on said
   atomizer wheel.

10. A machine according to any preceding claim, further comprising a monitor capable of indicating temperature in said
    interior environment.

11. A machine according to any preceding claim, further comprising a monitor capable of indicating humidity in said
    interior environment.

12. A machine according to any preceding claim, further comprising a trajectory control means to control trajectory of
    the particles from said atomizer wheel’s periphery to said catch tray.

13. A machine according to claim 12, wherein the trajectory control means comprises a unit for controlling size of said
    aperture, disposing steam valves at the periphery of said atomizer wheel, over said atomizer wheel and directly into
    said enclosure, and controlling airflow patterns at the periphery of said atomizer wheel.
14. A machine according to any preceding claim, further comprising a reactor for producing the polymer and at least one temperature-controlled conduit for feeding the polymer from the reactor to the distributor.

15. A machine according to claim 14, wherein the at least one conduit consists of a double jacket tube defining an inner passage for feeding the polymer to the distributor, and an outer envelope, surrounding the inner passage, through which a liquid may flow, to control temperature of the polymer.

16. A machine according any preceding claim, wherein said distributor is adapted to rotate in the same direction as said atomizer wheel.

17. A machine according to any preceding claim, wherein the distributor comprises a plurality of holes.

18. A machine according to claim 17, wherein the plurality of holes are disposed in a circle.

19. A machine according to claim 17, wherein the distributor has 24 holes.

20. A machine according to any preceding claim, wherein said atomizer wheel has a flat surface.

21. A machine according to any preceding claim, further comprising a shaft for receiving said atomizer wheel, said shaft being conical and tapered, so as to reduce vibrations during rotation of said atomizer wheel.

22. A machine according to any preceding claim, further comprising a shaft for receiving said atomizer wheel, said shaft having a threaded section for securing said atomizer wheel to said shaft.

23. A machine according to any preceding claim, further comprising a sorting bin for receiving and sorting the particles from said catch tray.

24. A machine according to any preceding claim, wherein said atomizer wheel has, at its perimeter, radially projecting teeth.

25. A machine according to any preceding claim, further comprising at least one baffle disposed within the enclosure, for regulating air flow within said internal environment.

26. A machine according to claim 25, wherein the at least one baffle is a plurality of baffles.

27. A machine according to claim 26, wherein the plurality of baffles comprises 4 baffles.

28. A method for producing porous polymer particles, which comprises supplying polymer to a machine according to any preceding claim, and allowing gas exchange through said aperture, thereby regulating temperature, humidity and air flow within said internal environment.

29. A method according to claim 28, further comprising varying size of said aperture, to vary a rate of gas exchange.

30. A method according to claim 28 or claim 29, wherein the polymer is agarose.

Patentansprüche

1. Zerstäubermaschine, die zur Herstellung von porösen Polymerartikeln verwendet werden kann und die folgendes umfaßt:
   a. ein Zerstäuberrad, das um eine Achse drehbar ist;
   b. einen Verteiler, um Polymermaterial im flüssigen Zustand auf das Rad aufzubringen;
   c. einen Auffangkorb, der unter dem Zerstäuberrad angeordnet ist, um Polymerpartikel aufzusammeln, die als ein Ergebnis des Abwerfens des Polymermaterials vom Rand des Rads gebildet werden, wenn das Rad rotiert;
   d. ein Gehäuse, das das Zerstäuberrad, den Verteiler und den Auffangkorb umschließt, wobei das Gehäuse eine Aufteilung zwischen einer inneren und äußeren Umgebung der Zerstäubermaschine definiert;
   e. eine Öffnung im Gehäuse, die Gasausstausch zwischen der inneren und äußeren Umgebung gestattet; und
f. Mittel zur Feuchtigkeits- und Temperatursteuerung in der inneren Umgebung.

2. Maschine nach Anspruch 1, wobei die Öffnung eine variable Größe hat.

4. Maschine nach Anspruch 3, wobei die Umfangswand allgemein kreisförmig ist.

5. Maschine nach Anspruch 4, wobei die Öffnung sich in Umfangsrichtung entlang der Umfangswand erstreckt.

6. Maschine nach Anspruch 4 oder 5, wobei die Umfangswand einen oberen Abschnitt und einen unteren Abschnitt umfaßt, wobei die Öffnung zwischen dem oberen Abschnitt und dem unteren Abschnitt definiert wird.

7. Maschine nach Anspruch 6, die des weiteren ein Stellglied umfaßt, um den oberen Abschnitt und den unteren Abschnitt relativ zueinander zu verschieben, um die Größe der Öffnung zu verändern.

8. Maschine nach Anspruch 7, wobei das Stellglied geeignet ist, den oberen Abschnitt entlang der Achse zu verschieben, um die Größe der Öffnung zu verändern.

10. Maschine nach einem der vorangegangenen Ansprüche, die des weiteren einen Monitor umfaßt, der geeignet ist, die Temperatur in der inneren Umgebung anzuzeigen.

11. Maschine nach einem der vorangegangenen Ansprüche, die des weiteren einen Monitor umfaßt, der geeignet ist, die Feuchtigkeit in der inneren Umgebung anzuzeigen.

12. Maschine nach einem der vorangegangenen Ansprüche, die des weiteren ein Bahnsteuerungsmittel umfaßt, um die Bahn der Partikel vom Umfang des Zerstäuberrads zum Auffangkorb zu steuern.

14. Maschine nach einem der vorangegangenen Ansprüche, die des weiteren ein Reaktorgefäß zur Herstellung des Polymers und wenigstens eine temperaturgesteuerte Leitung zur Zuführung des Polymers vom Reaktorgefäß zum Verteiler umfaßt.

15. Maschine nach Anspruch 14, wobei die wenigstens eine Leitung aus einer doppelwandigen Röhre besteht, die einen inneren Kanal zur Zuführung des Polymers zum Verteiler und eine den inneren Kanal umgebende äußere Hüle, durch den eine Flüssigkeit zur Temperatursteuerung des Polymers fließen kann, definiert.

17. Maschine nach einem der vorangegangenen Ansprüche, wobei der Verteiler mehrere Löcher umfaßt.

18. Maschine nach Anspruch 17, wobei die mehreren Löcher in einem Kreis angeordnet sind.

19. Maschine nach Anspruch 17, wobei der Verteiler 24 Löcher hat.

20. Maschine nach einem der vorangegangenen Ansprüche, wobei das Zerstäuberrad eine flache Oberfläche hat.
21. Maschine nach einem der vorhergehenden Ansprüche, die des weiteren einen Schaft zur Aufnahme des Zerstäuberrads umfaßt, wobei der Schaft konisch und sich verjüngend ist, um Vibrationen während der Rotation des Zerstäuberrads zu verringern.

22. Maschine nach einem der vorhergehenden Ansprüche, die des weiteren einen Schaft zur Aufnahme des Zerstäuberrads umfaßt, wobei der Schaft einen Gewindeabschnitt zur Befestigung des Zerstäuberrads am Schaft hat.

23. Maschine nach einem der vorhergehenden Ansprüche, die des weiteren einen Sortierbehälter zur Aufnahme und zum Sortieren der Partikel vom Auffangkorb umfaßt.

25. Maschine nach einem der vorhergehenden Ansprüche, die des weiteren wenigstens eine im Gehäuse angeordnete Prallfläche zur Regelung der Luftströmung in der inneren Umgebung umfaßt.

26. Maschine nach Anspruch 25, wobei die wenigstens eine Prallfläche mehrere Prallflächen sind.

27. Maschine nach Anspruch 26, wobei die mehreren Prallflächen 4 Prallflächen umfassen.

29. Verfahren nach Anspruch 28, das des weiteren eine veränderliche Größe der Öffnung umfaßt, um die Gasaustauschrate zu verändern.

30. Verfahren nach Anspruch 28 oder 29, wobei das Polymer Agarose ist.

Revendications

1. Machine d’atomisation, qui peut être utilisée pour la production de particules polymères poreuses, comprenant :
   a. une roue d’atomisation pouvant être mise en rotation autour d’un axe ;
   b. un distributeur pour déposer le polymère à l’état fluide sur ladite roue ;
   c. un tiroir de réception, disposé sous la roue d’atomisation, pour collecter les particules de polymère formées suite à l’éjection du polymère depuis le bord de la roue lorsque la roue d’atomisation est en rotation ;
   d. une enceinte, renfermant ladite roue d’atomisation, ledit distributeur et ledit tiroir de réception, ladite enceinte définissant une partition entre les environnements intérieur et extérieur de la dite machine d’atomisation ;
   e. une ouverture dans ladite enceinte, permettant un échange de gaz entre les environnements intérieur et extérieur, et
   f. des moyens pour contrôler la température et l’humidité dans l’environnement intérieur.

2. Machine selon la revendication 1, dans laquelle ladite ouverture et de taille variable.

3. Machine selon la revendication 2, dans laquelle ladite enceinte comprend une paroi périphérique entourant ladite roue d’atomisation, ledit distributeur et ledit tiroir de réception, et une partie de toit couvrant ladite paroi périphérique.

5. Machine selon la revendication 4, dans laquelle ladite ouverture s’étend sur la circonférence, le long de ladite paroi périphérique.

6. Machine selon la revendication 4 ou 5, dans laquelle ladite paroi périphérique comprend une partie supérieure et une partie inférieure, ladite ouverture étant définie entre ladite partie supérieure et ladite partie inférieure.

7. Machine selon la revendication 6, comprenant en outre, un appareil de commande pour déplacer ladite partie
supérieure et ladite partie inférieure l’une par rapport à l’autre, pour varier la taille de ladite ouverture.

8. Machine selon la revendication 7, dans laquelle ledit appareil de commande est fonctionnel pour déplacer ladite partie supérieure le long dudit axe, pour varier la taille de ladite ouverture.

12. Machine selon l’une quelconque des revendications précédentes, comprenant en outre, un moyen de contrôle de trajectoire pour contrôler la trajectoire des particules depuis la périphérie de ladite roue d’atomisation vers ledit tiroir de réception.

13. Machine selon la revendication 12, dans laquelle ledit moyen de contrôle de trajectoire comprend une unité pour contrôler la taille de ladite ouverture, disposer les vannes de vapeur à la périphérie de ladite roue d’atomisation, sur ladite roue d’atomisation et directement, dans ladite enceinte, et contrôler les motifs d’écoulement d’air à la périphérie de ladite roue d’atomisation.

17. Machine selon l’une quelconque des revendications précédentes, dans laquelle le distributeur comprend une série de trous.

18. Machine selon la revendication 17, dans laquelle la série de trous est disposée sur un cercle.

19. Machine selon la revendication 17, dans laquelle le distributeur à 24 trous.

23. Machine selon l’une quelconque des revendications précédentes, comprenant en outre une trémie de tri, pour recevoir et trier les particules dudit tiroir de réception.

26. Machine selon la revendication 25, dans laquelle la au moins une chicane est une série de chicanes.

27. Machine selon la revendication 26, dans laquelle la série de chicanes comprend 4 chicanes.

28. Procédé pour produire des particules polymères poreuses, qui comprend l’apport d’un polymère à une machine selon l’une quelconque des revendications précédentes, et le fait de permettre un échange gazeux par ladite ouverture, pour ainsi réguler la température, l’humidité et l’écoulement d’air dans ledit environnement interieur.

29. Procédé selon la revendication 28, comprenant en outre la variation de la taille de ladite ouverture, pour varier la vitesse de l’échange gazeux.

30. Procédé selon la revendication 28 ou 29, dans lequel le polymère est l’agarose.
FIG. 6
