Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

[0001] The present invention relates to a toolhead of the type identifiable by the features mentioned in the preamble of claim 1 appended.

[0002] The invention finds application in systems able to perform drilling, countersinking or other such machining operations automatically and to extremely close tolerances, in situations where the exact height of the machined surface is not known.

[0003] In particular, whilst implying no limitation of its general scope, the invention can be associated to advantage with numerically controlled multi-axis machine tools as used especially in the aircraft industry for drilling and countersinking holes in the outer panels of wing structures and fuselage sections, in readiness for the insertion of rivets. In practice, the heads of the inserted rivets must remain perfectly flush with the outer skin of the aircraft in order to ensure they will not generate turbulence, which would occasion a marked increase in aerodynamic resistance.

[0004] The prior art embraces devices able to control drilling or countersinking depth, which are set up by performing a mechanical adjustment before each machining job.

[0005] Patent IT 1220732, in particular, discloses a depth-controlled drilling and countersinking device able to operate on surfaces positioned at any given height relative to the feed direction of the tool. The device in question comprises a tool-holder with a shank that can be attached to the spindle of a machine tool, also a stop cage mechanism associated with the tool-holder by way of a pair of bearings and presenting a pair of cylinders with piston rods that project from both ends. Each of the rods is connected at one end to a collar, through which the tool is insertable when penetrating the work, and at the opposite end to a mounting plate. The collar is translatable relative to the tool-holder, in a direction parallel to the tool axis. The mounting plate associated with the ends of the rods remote from the tool carries respective micrometer screws that can be locked fast in a selected position by means of stops. Two microswitches are fixed to the spindlehead, their axes coinciding with those of the two micrometer screws. The microswitches are also connected to suitable devices serving to pilot the tool feed movement of the spindle. To control the depth of the countersink, the position of the screws is adjusted in such a way that the distance between the tip of the screw and the corresponding microswitch is equal to the distance between the face of the collar and the tool, plus the depth of the countersink. During operation, the spindle of the machine continues to advance until the screws engage and trip the microswitches. At this point, the devices piloting the movement of the spindle will be caused by the resulting contact to retract the tool. The machining depth is thus mechanically controlled, and the switches serve simply to halt the movement of the spindle once the prescribed depth has been reached.

[0006] The applicant finds that prior art devices of the type outlined above could be improved from various standpoints.

[0007] More exactly, mechanically controlled devices of familiar type such as the one described above do not allow any automatic adjustment of the depth to which the tool is sunk during the work cycle.

[0008] In practice however, an adjustment of this kind becomes necessary given that, whilst the shanks of the rivets utilized are generally identical, the dimensions of the respective heads will often vary. Accordingly, the single tool by which the hole is first drilled and then countersunk must penetrate to different depths according to the size of the rivet head that will ultimately occupy the hole. Furthermore, it may be that the cycle will involve sinking all of the holes initially, with different diameters one from another, and then countersinking each one in turn with a single tool penetrating to different depths as determined by the diameters of the different holes.

[0009] To this end, when using devices of the prior art type, the machine must always be stopped so as to allow manual adjustment of the micrometer screws.

[0010] It is also known from patent US5123789 a method of and apparatus for effecting a machining operation, e.g. drilling, on a multi-layered printed circuit board utilizing a machining apparatus having a spindle for driving a tool. The spindle is movable in the axial direction of the tool and a pressure foot for pressing the printed circuit board during the machining is mounted on the spindle for relative movement with respect thereto. The method includes the steps of determining the position of the end of a tool with respect to the end of a pressure foot in the state before the pressure foot contacts the printed circuit board, setting the amount of relative movement between the pressure foot and the tool necessary for effecting the desired machining, on the basis of the position of the end of the tool and a predetermined set value of the machining depth; and effecting the machining on the printed circuit board by controlling the feed of the tool in conformity with the amount of relative movement.

[0011] The object of the present invention is to resolve the problems encountered with prior art solutions by setting forth a toolhead for multi-axis machine tools as defined in claim 1, that will allow of sinking and countersinking holes automatically to different depths without any mechanical adjustment of the tool being required.

[0012] A further object of the invention is to provide a toolhead for multi-axis machine tools designed so as to allow a reduction of the down times between machining cycles, thereby optimizing production.

[0013] The stated objects and others besides will emerge more clearly from the following specification and are substantially realized in a toolhead for multi-axis machine tools, by virtue of the features as recited in the characterizing portion of claim 1 appended.

[0014] The invention will now be described in detail, by way of example, with the aid of the accompanying drawings, in which:
figure 1 illustrates a multi-axis machine tool equipped with a toolhead according to the present invention, viewed in perspective;

- figure 2 is an enlarged perspective view of the toolhead shown in figure 1;
- figure 3 is a sectional side elevation showing the toolhead of figure 2 attached to the spindle of the multi-axis machine;
- figures 4a and 4b show an enlarged detail of the toolhead in figure 2, illustrated during respective steps of operation.

[0015] Referring to the accompanying drawings, 1 denotes a toolhead according to the present invention, in its entirety.

[0016] The toolhead 1 is mounted to the spindlehead 2 of a numerically controlled multi-axis machine tool 3.

[0017] In general terms, the machine tool 3 comprises a bed 4 on which the spindlehead 2 is mounted with freedom of movement, relative to the bed 4, along a plurality of positioning axes. The spindlehead 2 is positioned on the various axes by drives means 5 of conventional embodiment (not described further), connected to a processing and control unit 6 and serving also to govern the rotation of the tool U about a relative machining axis J on the basis of data programmed into the control unit 6.

[0018] By way purely of example, the machine tool 3 shown schematically in figure 1 has five axes X, Y, Z, C and A with linear motors, and is designed to drill and countersink holes in parts of appreciable dimensions such as the panels and ribs of aircraft wings.

[0019] More specifically, the bed 4 of the machine 3 comprises two parallel slide ways 7 extending along a first positioning axis X, between which the work will be placed, and is surmounted by a gantry 8 traversable along the slide ways 7. The gantry 8 carries a first cross slide 9 traversable along the beam of the gantry 8, which coincides with a second positioning axis Y orthogonal to the first axis X and parallel to the floor. A second cross slide 10 mounted to the first slide 9 is traversable along a third positioning axis Z, extending perpendicular to the floor, and carries a rotary unit 11 at the bottom end centered on a fourth axis C parallel to the third axis Z. The spindlehead 2 is mounted to the rotary unit 11 and pivotable also about a fifth axis A orthogonal to the fourth axis C.

[0020] Referring to figures 2 and 3, the toolhead 1 is coupled to a spindle 12 in the spindlehead 2. More exactly, the toolhead 1 comprises a tool-holder 13 appearing as a cylindrical body centred on the machining axis J, of which one end 13a presents a spring collet 14 gripping the tool U, and the other end 13b presents a shank 15 that can be attached to the spindle 12 (indicated schematically).

[0021] The tool-holder 13 and the tool U are caused to rotate as one about the machining axis J, relative to the spindlehead 2, whilst the tool-holder 13 and the spindlehead 2 are rigidly associated one with another when moving along this same axis J.

[0022] The tool U shown in the accompanying drawings is furnished with a drill bit 16, and with a cutting portion 17 obtained by widening the shaft of the tool U so as to create a frustoconical surface that will countersink the hole drilled by the bit 16.

[0023] In an alternative solution, the tool U might be one comprising the conical countersink portion 17 only.

[0024] The toolhead 1 comprises a stop cage element 18 capable of sliding axially in relation to the tool-holder 13, and therefore to the spindlehead 2. The stop cage element 18 presents an active surface 19 disposed transverse to the machining axis J, such as can be offered in contact to a machinable work surface S (figures 4a and 4b). In the preferred embodiment of the drawings, the active surface 19 encircles the tool U circumferentially (figure 2).

[0025] The stop cage element 18 is capable of movement between a first operating position, in which the active surface 19 is located forward of the cutting portion 17 presented by the tool U, considered in the direction 20 along which the spindlehead 2 approaches the work surface S (figure 4a), and a second operating position in which the cutting portion 17 of the tool is located forward of the active surface 19, at least in part, as part of a work cycle to be described in due course.

[0026] In more detail, structurally, the toolhead 1 also incorporates an auxiliary housing 21 encasing the tool-holder 13 and presenting a first portion 21a adjacent to the spring collet 14, also a second portion 21b, adjacent to the shank 15, of which the diameter is greater than the diameter of the first portion 21a (figure 3).

[0027] The auxiliary housing 21 is mounted rotatably to the tool-holder 13 by way of a pair of bearings 22, while constrained to move as one with the selfsame tool-holder 13 along the direction of the machining axis J. The stop cage element 18 in turn is mounted slidably to the auxiliary housing 21.

[0028] More exactly, the stop cage element 18 presents a first cylindrical portion 18a ensheathing the first portion 21a of the housing 21, on which it is also slidable parallel to the machining axis J.

[0029] A second cylindrical portion 18b of the stop cage element 18 is joined coaxially and rigidly to the first portion 18a and extends beyond the collet 14 to a point of proximity with the cutting portion 17 of the tool U. One end 23 of the second cylindrical portion 18b of the stop cage element 18, the end nearer to the cutting portion 17, presents a thread engaged by a micrometer screw collar 24 affording the active surface 19.

[0030] A first circular seal 25a is positioned between the second cylindrical portion 18b of the stop cage element 18 and the auxiliary housing 21.

[0031] The stop cage element 18 is also connected to the auxiliary housing 21 by way of a pair of rods 26 accommodated slidably within the housing 21.

[0032] In particular, the rods 26 are anchored to the first cylindrical portion 18a of the stop cage element 18...
and extend parallel with the machining axis J toward the shank 15 of the tool-holder 13, passing through passages 27 created especially in the second portion 21b of the auxiliary housing 21. A first end 26a of each rod 26 is inserted stably into the first cylindrical portion 18a of the stop cage element 18, whilst the second end 26b of the rod 26 projects from the second portion 21b of the auxiliary housing 21, facing the spindlehead 2. The second ends 26b of the two rods 26 are anchored to a plate 28 encircling the tool-holder 13.

[0033] The toolhead 1 further comprises spring means 29 operating between the stop cage element 18 and the auxiliary housing 21, in such a manner as to bias the selfsame stop cage element 18 toward the first operating position.

[0034] In the example illustrated, such spring means 29 are embodied as two coil springs, each ensheathing a respective rod 26 with one end seated against the stop cage element 18 and the opposite end seated against the auxiliary housing 21.

[0035] The mechanical structure of the toolhead 1 as described thus far is designed in such a way that the stop cage element 18 and the assembly composed of the tool-holder 13 and the auxiliary housing 21 are allowed freedom of relative movement, parallel to the machining axis J, between two travel limit positions compassing the first and second operating positions.

[0036] As long as the active surface 19 is not directed against any work surface S, the toolhead 1 will be kept in the first limit position by the action of the coil springs 29. In this situation the plate 28 is positioned tight against the second portion 21b of the auxiliary housing 21.

[0037] In the second limit position, the stop cage element 18 is forced against a shoulder 21c located at the junction between the first portion 21a and the second portion 21b of the auxiliary housing 21. The space adjacent to the shoulder 21c is occupied by a second circular seal 25b, positioned between the first cylindrical portion 18a of the stop cage element 18 and the auxiliary housing 21.

[0038] Advantageously, the toolhead 1 further comprises sensing means 30 able to monitor the axial position of the stop cage element 18, continuously, relative to the tool-holder 13.

[0039] Likewise advantageously, the sensing means 30 of the toolhead 1 are connected to the processing and control unit 6 of the machine tool 3 in such a way as will allow the axial feed of the spindlehead 2 to be interlocked to the countersink depth value programmed in the selfsame control unit 6.

[0040] The aforementioned sensing means 30 comprise at least one displacement sensor 31 connected to a processing unit 32 interfaced or integrated with the main control unit 6. In effect, the electronics needed to handle the signal from the sensor 31 can be either incorporated into the main control unit 6 or procured as a separate unit 32 installed between the sensor 31 and the control unit 6.

[0041] The sensor 31 is required to detect a relative displacement of the stop cage element 18 and the tool-holder 13. Given that the tool-holder 13 moves as one with the spindlehead 2 along the machining axis J, the sensor 31 will be positioned preferably so as to detect a relative displacement between the stop cage element 18 and the spindlehead 2.

[0042] The sensor 31 can be of any given type as long as it is able to produce an output signal proportional to the relative displacement between the components in question.

[0043] In a preferred first embodiment of the present invention, the displacement sensor 31 would be a Linear Variable Differential Transformer or “LVDT” transducer of familiar type, mounted between the spindlehead 2 and the stop cage element 18. For example, the cylinder of the LVDT transducer could be anchored to the spindlehead 2 and the plunger rod offered to the plate 28 associated with the stop cage element 18.

[0044] In a second embodiment of the present invention, the displacement sensor 31 might be a measuring probe mounted in exactly the same way as the LVDT transducer.

[0045] Alternatively, and in a third possible embodiment of the invention, the displacement sensor 31 could be an inductive transducer operating between the spindlehead 2 and the stop cage element 18. By way of example, as indicated in figure 3, the inductive transducer 31 could be mounted to the spindlehead 2 and directed at the plate 28 associated with the stop cage element 18, the plate 28 in this instance being necessarily metallic.

[0046] Finally, in a fourth embodiment, the displacement sensor 31 could take the form of a laser device operating between the spindlehead 2 and the stop cage element 18. Likewise in this instance, the laser device would be mounted preferably to the spindlehead 2 and directed toward the plate 28 associated with the stop cage element 18.

[0047] Following a description concerned thus far with predominantly structural aspects, the operation of a machine tool equipped with a toolhead according to the present invention will now be described, and in particular the single operation of drilling and countersinking a hole.

[0048] The processing and control unit 6 is programmed to drill and to countersink a given number of holes on a known nominal surface, each countersunk to a predetermined depth H.

[0049] A tool U of the type illustrated is fitted to the tool-holder 13, and the position of the micrometer collar 24 adjusted, if necessary, relative to the frustoconical cutting portion 17 that will form the countersink, in such a way as to bring the leading edge of the selfsame frustoconical portion 17 into alignment with the active surface 19. The position in question can be checked with extreme precision, for example with the aid of scanning means.

[0050] The machine 3 begins its automatic work cycle, drilling a hole in the surface S by advancing the spindlehead 2 toward the work. During the course of the approach, the tip P of the tool penetrates the work while the
A toolhead for multi-axis machine tools, comprising:

1. A tool-holder (13) rotatable about a respective machining axis (J), equipped with a collet (14) in which to hold a tool (U), and attachable to the spindle (12) of a spindlehead (2) in a multi-axis machine tool (3); a stop cage element (18) slidably axial relative to the tool-holder (13), affording an active surface (19) set transverse to the machining axis (J) and positionable against the surface (S) of a workpiece, capable of movement between a first operating position in which the active surface (19) is located forward of a cutting portion (17) presented by the tool (U), relative to a feed direction (20) along which the spindlehead (2) approaches the surface (S) of the tool, and a second operating position in which the cutting portion (17) of the tool is located forward of the active surface (19), at least in part,

wherein it further comprises sensing means (30) by which the axial position of the stop cage element (18) relative to the tool-holder (13) is monitored continuously; the toolhead being characterised in that it further comprises an auxiliary housing (21) mounted rotatably to the tool-holder (13) and associated rigidly with the same tool-holder (13) in the axial direction, wherein the stop cage element (18) is mounted slidably to the auxiliary housing (21).

2. A toolhead as in claim 1, wherein sensing means (30) comprise at least one displacement sensor (31) connected to a processing unit (32).

3. A toolhead as in claim 1, wherein the displacement sensor (31) is an LVDT transducer.

4. A toolhead as in claim 3, wherein the LVDT transducer is mounted between the spindlehead (2) and the stop cage element (18).

5. A toolhead as in claim 1, wherein the displacement sensor (31) is a measuring probe.

6. A toolhead as in claim 5, wherein the measuring probe is mounted between the spindlehead (2) and the stop cage element (18).

7. A toolhead as in claim 1, wherein the displacement sensor (31) is an inductive transducer.

8. A toolhead as in claim 7, wherein the inductive transducer is mounted between the spindlehead (2) and the stop cage element (18).

9. A toolhead as in claim 1, wherein the displacement sensor (31) is a laser displacement sensor.

10. A toolhead as in claim 9, wherein the laser displacement sensor is mounted between the spindlehead (2) and the stop cage element (18).

11. A toolhead as in claim 1, wherein the stop cage element (18) is mounted to the auxiliary housing (21) by way of a pair of rods (26) accommodated slidably within the same housing (21).

12. A toolhead as in claim 1, further comprising spring
means (29) operating between the stop cage element (18) and the auxiliary housing (21), by means of which the stop cage element (18) is biased toward the first operating position.

13. A multi-axis machine tool, comprising:

- a bed (4);
- a spindlehead (2) mounted to the bed (4) and capable of movement relative to the bed (4) on a plurality of positioning axes (X, Y, Z, C, A);
- drive means (5) by which the spindlehead (2) is positioned on the various axes (X, Y, Z, C, A);

characterized in that it comprises a toolhead (1) according to claim 1; and in that the sensing means (30) of the toolhead (1) are connected to a processing and control unit (6) in such a way that the axial movement of the spindlehead (2) can be controlled according to a selected machining depth programmed into the selfsame processing and control unit (6).

Patentansprüche

1. Werkzeughalterkopf für mehrachsige Werkzeugmaschinen, enthaltend:

- einen um eine jeweilige Bearbeitungssachse (J) drehbaren Werkzeughalter (13), ausgestattet mit einer Spannpatrone (14), in welcher ein Werkzeug (U) gehalten wird, und anbringbar an einer Spindel (12) eines Spindelkopfstückes (2) in einer mehrachsigem Werkzeugmaschine (3);
- ein axial im Verhältnis zu dem Werkzeughalter (13) verschiebbares Druckanschlagelement (18), das eine aktive Oberfläche (19) quer zu der Bearbeitungssachse (J) aufweist und an der Oberfläche (S) eines Werkstückes positionierbar ist, in der Lage, eine Bewegung auszuführen zwischen einer ersten Arbeitsposition, in welcher die aktive Oberfläche (19) dem von dem Werkzeug (U) aufgewiesenen Schneidabschnitt (17) voraus angeordnet ist, im Verhältnis zu einer Vorschubrichtung (20), entlang welcher sich der Spindelkopf (2) der Oberfläche (S) des Werkstückes nähert, und einer zweiten Arbeitsposition, in welcher der Schneidabschnitt (17) des Werkzeugs wenigstens zum Teil der aktiven Oberfläche (19) voraus angeordnet ist, wobei er ausserdem Fühlermittel (30) enthält, montiert drehbar an dem Werkzeughalter (13) und in axialer Richtung starr mit dem Werkzeughalter (13) selbst verbunden, und bei welchem das Druckanschlagelement (18) gleitbar an dem Hilfsgehäuse (21) montiert ist.

2. Werkzeughalterkopf nach Patentanspruch 1, bei welchem die Fühlermittel (30) wenigstens einen Verschiebungsfühler (31) enthalten, der an eine Verarbeitungseinheit (32) angeschlossen ist.

3. Werkzeughalterkopf nach Patentanspruch 1, bei welchem der Verschiebungsfühler (31) ein LVDT-Wandler ist.

5. Werkzeughalterkopf nach Patentanspruch 1, bei welchem der Verschiebungsfühler (31) eine Messsonde ist.

6. Werkzeughalterkopf nach Patentanspruch 5, bei welchem die Messsonde zwischen dem Spindelkopf (2) und dem Druckanschlagelement (18) montiert ist.

7. Werkzeughalterkopf nach Patentanspruch 1, bei welchem der Verschiebungsfühler (31) ein induktiver Wandler ist.

8. Werkzeughalterkopf nach Patentanspruch 7, bei welchem der induktive Wandler zwischen dem Spindelkopf (2) und dem Druckanschlagelement (18) montiert ist.

1. Une tête porte-outils pour machines-outils multiaxes, comprenant :

un porte-outils (13) pouvant tourner autour d’un axe d’usinage (J) respectif, équipé d’une pince de serrage (14) pour le blocage d’un outil (U) et pouvant être accouplé avec la broche (2) d’une machine-outil multiaxes (3) ; un élément presseur (18) pouvant coulisser axialement par rapport au porte-outils (13) et présentant une surface active (19) disposée transversalement à l’axe d’usinage (J) et pouvant être amenée contre la surface (S) d’une pièce à usiner, ledit élément presseur (18) étant mobile entre une première position opérationnelle dans laquelle la surface active (19) est située au-delà d’une partie de coupe (17) de l’outil (U), par rapport à une direction (20) d’avancement du chariot porte-broche (2) vers la surface (S) à usiner, et une deuxième position opérationnelle dans laquelle la partie de coupe (17) de l’outil est située, au moins en partie, au-delà de la surface active (19), où ladite tête porte-outils comprend en outre des moyens de détection (30) destinés à contrôler en permanence la position axiale de l’élément presseur (18) par rapport au porte-outils (13) ; la tête porte-outils étant caractérisée en ce qu’elle comprend en outre un logement auxiliaire (21) monté de façon rotative sur le porte-outils (13) et axialement solidaire dudit porte-outils (13), où l’élément presseur (18) est monté de façon coulissante sur le logement auxiliaire (21).

2. La tête porte-outils selon la revendication 1, caractérisée en ce que les moyens de détection (30) comprennent au moins un capteur de déplacement (31) relié à une unité de traitement (32).

3. La tête porte-outils selon la revendication 1, caractérisée en ce que le capteur de déplacement (31) est un transducteur LVDT.

4. La tête porte-outils selon la revendication 3, caractérisée en ce que le transducteur LVDT est monté entre le chariot porte-broche (2) et l’élément presseur (18).

5. La tête porte-outils selon la revendication 1, caractérisée en ce que le palpeur de mesure est monté entre le chariot porte-broche (2) et l’élément presseur (18).

6. La tête porte-outils selon la revendication 5, caractérisée en ce que le palpeur de mesure est monté entre le chariot porte-broche (2) et l’élément presseur (18).

7. La tête porte-outils selon la revendication 1, caractérisée en ce que le capteur de déplacement (31) est un transducteur inductif.

8. La tête porte-outils selon la revendication 7, caractérisée en ce que le transducteur inductif est monté entre le chariot porte-broche (2) et l’élément presseur (18).

9. La tête porte-outils selon la revendication 1, caractérisée en ce que le capteur de déplacement (31) est un capteur laser de déplacement.

10. La tête porte-outils selon la revendication 9, caractérisée en ce que le capteur laser de déplacement est monté entre le chariot porte-broche (2) et l’élément presseur (18).

11. La tête porte-outils selon la revendication 1, caractérisée en ce que l’élément presseur (18) est monté sur le logement auxiliaire (21) par l’intermédiaire d’une paire de tiges (26) logées de façon coulissante dans ce même logement (21).

12. La tête porte-outils selon la revendication 1, caractérisée en ce qu’elle comprend en outre des moyens élastiques (29) agissant entre l’élément presseur (18) et le logement (21) et par l’intermédiaire desquels l’élément presseur (18) lui-même est poussé vers la première position opérationnelle.

13. Une machine-outil multiaxes, comprenant :
un bâti (4) ;
un chariot porte-broche (2) monté sur le bâti (4) et mobile par rapport audit bâti (4) selon une pluralité d’axes de positionnement (X, Y, Z, C, A) ;
des moyens d’entraînement (5) pour le positionnement du chariot porte-broche (2) sur les différents axes (X, Y, Z, C, A) ;

_**caractérisée en ce qu’elle comprend une tête porte-outils (1) selon la revendication 1 ; et en ce que les moyens de détection (30) de la tête porte-outils (1) sont reliés à une unité de traitement et de contrôle (6) de manière à ce que le mouvement axial du chariot porte-broche (2) puisse être piloté selon une profondeur d’usinage donnée programmée dans ladite unité de traitement et de contrôle (6).**_
