Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

[0001] The present invention relates to an improved pen needle and safety shield system particularly, but not exclusively, adapted for pen injectors. The safety shield system in accord with aspects of this invention include a retractable generally tubular shield which is spring-biased to normally enclose the needle cannula of a pen needle dispenser, but which locks in the extended position enclosing the needle cannula following injection. Further, the double-ended needle cannula assembly may be safely nested in the cup-shaped cap following injection for disposal.

[0002] Hypodermic syringes are used to deliver selected doses of fluids including liquid medicaments, inoculations, etc. to patients. However, many applications using hypodermic needles are self-administered, including, for example, insulin, anti-histamines, et cetera. The required manipulation of a standard prior art hypodermic syringe can be inconvenient, particularly where the injection is self-administered in a public environment. Medication delivery pens or pen injectors have therefore been developed to facilitate self-administration of injections. A typical pen injector includes a generally tubular body portion resembling a fountain pen which receives a vial of fluid, such as insulin, anti-histamines, et cetera, having a pierceable closure, such as a rubber septum. The pen needle includes a hub generally having a double-ended needle cannula including a first end which extends into the body portion of the pen injector for piercing the closure of the vial and a second end used for self-injection of the fluid contained in the vial. The pen needle also generally includes a removable cup-shaped cap which encloses the second end of the needle cannula prior to use.

[0003] Various improvements in pen needles have been developed or proposed since their introduction, including adjustable injection length pen needles as disclosed in U.S. Patent No. 5,944,700 assigned to the assignee of the present application and safety shield systems for such pen needles, wherein the shield is generally cup-shaped including an open end which receives the body portion of the pen needle and a generally closed end portion having a central opening which receives the second end of the needle cannula when the shield is retracted from a first position enclosing the second end of the needle cannula to a second position wherein the needle cannula is exposed for injection. The assembly may further include a spring that biases the shield to the normally enclosed first position prior to injection.

[0004] Various safety shield systems have also been developed or proposed by the prior art for conventional hypodermic syringes wherein a tubular shield is spring biased to enclose the needle cannula following injection and including safety shields which lock in the extended enclosed position following injection. Such safety shield systems for conventional hypodermic syringes are operated manually or are spring biased to extend the tubular shield and enclose the needle cannula following injection but all require additional action "active systems" such as force, to activate as compared to the standard injection process. Hand manipulated safety shield systems may include spiral or complicated channel-shaped tracks on an inside surface of the shield which guide the shield during extension of the shield to enclose the needle cannula and lock the shield in the extended position. However, such complicated track systems may not always be reliable. A document disclosing a safety shield system is US 2002/0046448.

[0005] There is a need for a safety shield system for pen needles, wherein the shield initially encloses the second end of the needle cannula prior to use, permits retraction of the shield for self-administration of the fluid in the pen needle dispenser and then extends and locks the shield in the extended position enclosing the needle cannula following use. It would also be desirable to simplify the operation of the shield to eliminate manual manipulation or rotational movement of the shield from the retracted position to a locked extended position.

[0006] One concern with certain pen needle accessories, such as hidden needle adapters, has been potential needle sticks to the user during assembly of the accessory on the pen injector. Because the shield must be retractable for injection and the shield and cap assembly is typically threaded on the pen needle dispenser, the natural tendency of the user or patient is to press the cap toward the injector during assembly. This may cause the needle cannula to pierce the cap and possibly puncture the user during assembly. Another concern associated with pen needles has been the safe disposal of the hub and double-ended needle cannula. As will be understood, one end of the double-ended needle cannula may be enclosed in the cup-shaped cap; however, the other end is exposed following removal of the hub assembly from the pen injector.

[0007] The pen needle and safety shield system in accord with one aspect of this invention solves these problems by providing a safety shield which normally encloses the needle cannula prior to use, permits retraction of the safety shield during injection and automatically extends and locks the shield in the extended enclosed position following use. The pen needle of this invention also prevents retraction of the shield during assembly of the shield and needle cannula and hub assembly on the pen injector. Further, the improved safety shield system of this invention permits safe disposal of the hub and double-ended needle cannula assembly following removal from the pen injector.

SUMMARY OF THE INVENTION

[0008] As set forth above, the improved safety shield system in accord with one aspect of this invention is particularly but not exclusively adapted for pen injectors. That is, although the safety shield system of this invention is specifically designed for use with pen injectors of the type described herein, the safety shield system of this
invention may also be used with other devices including conventional hypodermic needle fluid delivery systems. For ease of description, however, the safety shield system of this invention will now be described as a component of a pen injector. As set forth above, such pen injectors generally include a tubular body portion adapted to receive a conventional vial for dispensing a fluid, such as insulin, anti-histamines, et cetera. A conventional pen needle dispenser further includes a needle cannula hub assembly wherein the hub is generally cup-shaped including a tubular portion having an open end whichthreadably receives the tubular end portion of the pen injector and a closed end portion which receives and secures the needle cannula. The tubular portion of the hub may be threadably or otherwise attached to the tubular end portion of the pen injector. The needle cannula extends through the end portion of the hub and includes a first end portion which extends into the body portion of the pen injector for piercing the closure in the vial and an opposed second end portion used for injection of a patient, including self-injection.

[0009] Certain implementations of improved safety shield system include a generally tubular clip member preferably having a tubular body portion received around the tubular hub portion of the hub assembly and a plurality of spaced laterally projecting resilient fingers. The free ends of the resilient fingers are hook-shaped opening toward the body portion of the pen injector. The safety shield system further includes a generally tubular reciprocable shield having a first tubular portion surrounding the clip member and a second tubular portion normally surrounding the second end of the needle cannula. As described below, the shield is spring biased to normally extend the second portion of the shield around the needle cannula. The shield may also include a plurality of spaced axially extending inwardly opening channel-shaped tracks on an inner surface of the shield which receive the resilient fingers of the clip member. During reciprocal motion of the shield as described above, the axially extending channel-shaped tracks guide the shield from a first position, wherein the shield second portion surrounds the second end of the needle cannula, to a second position, wherein the second end of the needle cannula is exposed for injection of a patient. The safety shield system further includes a spring resiliently biasing the shield axially to normally extend the shield second portion to surround the second end of the needle cannula. Thus, during use of the pen injector, the health care worker or patient presses the end of the shield against the area to be injected, which retracts the shield to the second position against the force of the spring. In a preferred embodiment, the shield is cup-shaped including the first and second tubular portions described above and a generally closed end portion having a central opening which receives the second end of the needle cannula therefore during injection. Following use, the spring automatically extends the shield to enclose the second end of the needle cannula.

[0010] The shield includes an opening spaced from but near the open end of the shield, and means is provided to prevent the free end of the resilient finger from being received in the opening during retraction of the shield from the first position enclosing the second end of the needle cannula to expose the needle cannula as described. Thus, the shield may be retracted to expose the second end of the needle cannula during injection, but the resilient finger will lock into the opening when the spring extends the shield to enclose the second end of the needle cannula following injection. The shield is thereby locked in the first position enclosing the second end of the needle cannula following injection. The free end of the resilient fingers are hook-shaped as described above and the hook-shaped portion of the finger is received through the opening and securely locks the shield in the closed position. In a preferred embodiment, each of the channel-shaped tracks include an opening which receives and secures each of the locking fingers. The improved safety shield system thus permits one retraction of the safety shield during injection and locks the safety shield to enclose the second end of the needle cannula following injection. Although various means may be utilized in accord with the invention to prevent receipt of the locking fingers in the openings during retraction of the safety shield to expose the needle cannula, one embodiment includes a resilient detent or finger portion in the tracks adjacent the opening which resiliently biases the fingers of the clip member inwardly, such that the resilient fingers of the clip member travel past the opening during retraction of the shield member to the second position as described above. Further, the resilient detents catch the hook-shaped end portions of the resilient fingers during extension of the shield, assuring locking of the shield in the extended position following injection. Another embodiment has the hook-shaped portion of the finger being larger than the opening such that the finger slides over the opening when the shield is moved to the second position. The openings include a chamfer which catch the hook-shaped portions of the fingers when the shield is returned to the first position.

[0011] The safety shield system further includes a removable cup-shaped cap which is received the shield prior to use. As will be understood, the cap is then removed and the pen injector is ready for use as described above. However, the cap of the improved safety shield system of this invention may also be used to safely store and dispose of the double-ended needle cannula. As described above, the second end of the needle cannula is protected following injection by the safety shield which is locked in the extended position surrounding the second end of the needle cannula. The needle cannula and safety shield system may then be safely stored in the cap for disposal by removing the needle cannula and safety shield assembly from the pen injector and inserting the first end of the needle cannula into the cup-shaped cap which is configured and adapted to receive and store the assembly for safe disposal. That is, the first end of the
needle cannula is then located in the cup-shaped cap preventing exposure to the needle cannula and the second end portion is safely enclosed by the safety shield which is locked in the extended position protecting the second end of the needle cannula. The subject invention includes a top cap and a bottom cap which interlock with each other to completely encompass the needle cannula.

[0012] The safety shield system in accord with aspects of this invention thus provides reliable operation and protection from the needle cannula. In certain implementations, the generally tubular safety shield moves axially guided by the axially extending channel-shaped tracks as described above, thereby eliminating rotational movement of the shield or a complex track system. The tubular body portion of the clip member includes a plurality of spaced axially extending radially projecting ribs which are received in axially extending grooves in the tubular portions of the shield, assuring axial movement of the shield during retraction and extension of the shield as described above. The resilient fingers of the clip member include a U-shaped portion integrally connected to the tubular portion of the clip member and hook-shaped free end portions as described above. This configuration provides additional resiliency for the hook-shaped end portions of the fingers. Further, the U-shaped portion of the fingers preferably open toward the generally closed end of the shield and the spring includes a first end received in the U-shaped portions of the fingers and a second end biased against the generally closed end of the shield assuring reliable movement of the shield.

[0013] The pen needle and safety shield system of this invention also prevents retraction of the shield during assembly of the safety shield system on the pen injector. As set forth above, one problem with certain pen needles has been potential piercing of the cap during threaded assembly of the cap and shield assembly on the pen dispenser thereby exposing the user to puncture. The cap of the improved safety shield system includes a plurality of radially inwardly projecting ribs which are received in the axially extending grooves in the tubular portion of the shield against the axially projecting ribs on the clip member. The grooves in the tubular portion of the shield preferably extend through the sidewall of the shield from adjacent the generally closed end to the ribs. These internal ribs on the cap prevent retraction of the shield during threaded assembly of the cap and shield assembly on the pen injector, thereby preventing accidental puncture during assembly.

[0014] The pen needle and safety shield system in accord with aspects of this invention thus permits normal operation of the safety shield to retract the shield during injection and automatically extends and locks the shield following injection to prevent inadvertent contact with the second end of the needle cannula. Further, as described above, the needle cannula assembly may then be safely stored in the cup-shaped cap or cover for disposal where-in the first end of the needle cannula is located in the cup-shaped cover and the second end is protected by the safety shield. Other advantages and meritorious features of the pen needle and safety shield system of this invention will be more fully understood from the following description of the embodiments, the appended claims and the drawings, a brief description of which follows.

BRIEF DESCRIPTION OF THE DRAWINGS

[0015] Figure 1 is a side view of one pen needle and safety shield system with the cap removed;

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0030] As set forth above, the improved safety shield system is particularly but not exclusively adapted for pen injectors, such as the pen needles available from Becton Dickinson and Company best shown at 20 in Figures 1 and 2. As will be understood, however, the safety shield system of this invention may also be used with other pen injectors of this general type and with conventional hypodermic syringes and drug delivery devices.

[0031] As described below, a safety shield 22 normally encloses a second end 38 of a needle cannula 34 as
shown in Figure 2 and a safety shield assembly 23 is enclosed by a cup-shaped cap 24 as shown in Figure 1. The implementation of the pen injector 20 includes an open end 26 which may include external ribs 28 to facilitate gripping of the pen needle 20 by the user for threadable attachment of the safety shield assembly 23 to the pen injector 20 as described below. As shown in Figure 2, the pen injector 20 receives a vial shown in phantom at 30 having a pierceable closure such as a rubber septum (not shown) in an open tubular end portion 31 of the vial. The pen injector 20 further includes a needle cannula and hub assembly 32 that includes the needle cannula 34 which extends through a hub member 40 to define a first end 36 that extends into the pen injector 20 to pierce the closure of the vial 30 or other container and the second opposed end 38 used for injection, including self-administration as described above. The hub member 40 includes a tubular rim portion 42 that is preferably threadably received on a tubular end portion 44 of the pen injector 20 and a central portion 46 that receives and secures the needle cannula 34. The needle cannula 34 includes a lumen or small passage therethrough for transferring fluid in the vial 30 to the user for self-injection or administration by a health care worker. The tubular rim portion 42 of the hub member 40 may include internal threads for threaded receipt of the hub member 40 on the externally threaded end portion 44 of the pen injector 20.

[0032] The safety shield system includes a generally tubular clip member 48 having a tubular body portion 50 which is received around the tubular rim portion 42 of the hub member 40, as shown in Figure 2, and a plurality of laterally projecting resilient hook-shaped fingers 52. The clip member 48 may be formed of a resilient polymeric material, such as polypropylene, such that the fingers 52 are able to flex inwardly and resiliently flex outwardly as described below. Alternatively, the clip member 48 may be formed of a metal stamping or may be integrally formed with hub member 40. As shown in Figure 2, for example, the fingers 52 are supported on a U-shaped portion 54 which further improves the resiliency of the fingers as they flex inwardly and spring outwardly. The clip member 48 further includes a plurality of circumferentially spaced axially extending ribs 56 which prevent rotational movement of the shield 22 and guide the shield 22 during axial movement of the shield 22 as described below.

[0033] Referring also to Figures 3 and 4, the safety shield 22 is generally tubular having an open end 58 and preferably including a generally closed end 60 having an axial opening 62 therethrough which receives the second end 38 of the needle cannula 34 as described below. The shield 22 further includes a plurality of circumferentially spaced longitudinally or axially extending channel-shaped tracks 64 in an internal surface of the tubular portion of the shield 22 that receives the hook-shaped fingers 52 and a plurality of circumferentially spaced axially extending slots or grooves 66 which receive the radial ribs 56 on the clip. As will be understood, the longitudinal axis of the safety shield 22 is coincident with the needle cannula 34. The axial channel-shaped tracks 64 each include a radial opening 68 which is generally adjacent to but spaced from the open end 58 of the shield 22. Each of the axial channel-shaped tracks 64 may include an inwardly projecting resilient integral tang or finger portion 70 adjacent the opening 68 closest to the open end 58 as seen in Figure 4. The resilient tangs or finger portions 70 resiliently bias the hook-shaped fingers 52 inwardly and preferably include a ledge 72 releasably retaining the shield 22 in the extended position prior to injection as shown in Figure 2 and further described below.

[0034] A coil spring 74 is biased between the clip member 48 and the generally closed end 60 of the shield 22, resiliently urging the shield 22 toward the extended position to enclose the second end 38 of the needle cannula 34, as shown in Figure 2. The inside surface of the shield 22 includes a plurality of circumferentially spaced radially projecting ribs 76 that center the coil spring 74 in the shield 22. The cup-shaped cap 24 includes a closed end 80 and an open end 78. The open end receives the safety shield assembly 23 and needle cannula and hub assembly 32. The internal surface of the cap 24 includes a plurality of radially projecting ribs 84 that extend axially from adjacent the closed end 80 to the ends of the radial ribs 56 which prevent retraction of the safety shield 22 during assembly on the pen injector 20. The external surface of the cap 24 may also include ribs 82 to assist in gripping the cap 24 during assembly of the safety shield assembly 23 on the pen injector 20. The closed end 80 of the cap 24 also includes an inwardly projecting dimple 86 which is received in the opening 62 of the shield 22 centering the cap 24 on the shield 22. Other details of the safety shield assembly 23 will be discussed below in the description of the assembly and operation of the pen needle and safety shield system.

[0035] First, the operation of one implementation of the pen needle and safety shield system will now be described. One important advantage of the safety shield assembly 23 is that it may be preassembled with the needle cannula and hub assembly 32 and supplied to the patient or end user as an assembly ready for use. The first step taken by the patient or end user is then to attach this combined assembly to the pen injector 20 by threading the tubular rim portion 42 of the needle cannula and hub assembly 32 onto the tubular end portion 44 of the pen injector 20. As can be seen from Figure 2, the internal ribs 84 on the cap 24 are aligned with the ribs 56 of the clip member 48 and prevent inadvertent depression or retraction of the safety shield assembly 23. Such depression or retraction could drive the second end 38 of the needle cannula 34 through the opening 62 of the shield 22 and puncture the cap 24, thereby exposing the end user to the needle cannula 34. The vial 30 may be previously loaded into the pen injector 20 and the open end 26 may be closed by an end cap (not shown), such that
the threaded assembly results in piercing the first end 36 of the needle cannula 34 through the closure, such as a rubber septum, in the open end 31 of the vial 30 as the tubular rim portion 42 of the hub member 40 is threaded onto the rim portion 44 of the pen injector 20. Alternatively, the vial 30 may be inserted into the pen injector 20 following assembly.

[0036] Once the vial is inserted in the pen injector 20, the cap 24 is removed from the assembly as shown in Figures 1 and 5. The pen needle and safety shield assembly is then ready for use.

[0037] As set forth above, the safety shield assembly 23 is particularly, but not exclusively, suitable for pen needle injectors typically used for self-administration of fluid or liquid drugs, vaccines or medicament, such as insulin, anti-histamines, et cetera. During use, the patient simply depresses the generally closed end 60 of the safety shield 22 against the body area to be injected, as shown in Figure 6. As shown in Figures 2 and 5, the hook-shaped fingers 52 are releasably retained by the inwardly projecting tangs or finger portions 70 of the shield 22 preventing inadvertent retraction of the shield 22 and providing some resistance to movement of the shield 22 during injection. Further, the fingers 52 are resiliently biased inwardly by the shield 22, such that retraction of the shield 22 when the generally closed end 60 of the shield 22 is pressed against the skin causes the fingers 52 to move over the openings 68 and move into the channel-shaped tracks 64 during initial retraction of the shield 22, exposing the second end 38 of the needle cannula 34 which is received through the opening 62 of the shield 22, resulting in injection of the patient. The top of the fingers may be longer than the opening in the axial direction. Consequently, during actuation of the shield 22 (as seen in Figs. 6 and 14), the top portion of the finger does not contact the top of the opening during such actuation. Rotation of the shield 22 relative to the needle cannula and hub assembly 32 is prevented by the ribs 56 which follow the axial slots or grooves 66 assuring axial movement of the shield 22.

[0038] Following injection, the needle cannula 34 is withdrawn from the patient and the shield 22 is simultaneously extended by the coil spring 74, such that the second end 38 of the needle cannula 34 is never exposed. The shield 22 is extended axially as the needle cannula 34 is withdrawn because the hook-shaped fingers 52 move in the axial channel-shaped track 64 and the radial ribs 56 move through the slots or grooves 66. Upon full extension of the shield 22 to enclose the second end 38 of the needle cannula 34, the hook-shaped fingers 52 are received through the openings 68 and the hook-shaped portion is received around the inwardly projecting tang 70, locking the shield 22 in the extended position as shown in Figure 7. The shield 22 cannot be retracted that is, moved downwards shown in Fig. 7 following injection to re-expose the second end 38 of the needle cannula 34.

[0039] After use, the safety shield assembly 23 may be removed from the pen injector 20 by unthreading the tubular rim portion 42 of the hub member 40 from the threaded tubular end portion 44 of the pen injector 20 and safely disposed of directly into a sharps container or by reversing this assembly and inserting the assembly into the cup-shaped cap 24 as shown in Figure 8. The first sharp end 36 of the needle cannula 34 is thus safely received in the cup-shaped cap 24 and the second end 38 of the needle cannula is protected by the safety shield 22, which is locked in the extended position, providing for safe disposal of the entire assembly. The internal ribs 84 of the cap 24 may be designed to provide an interference fit with the safety shield assembly 23, thereby preventing inadvertent removal of the assembly from the cap 24 and inadvertent exposure to either end of the needle cannula 34 following disposal. As shown in Fig. 8, one or more of the ribs 84 may include a ball-shaped end portion 90 which is received in a socket 92, securing the assembly in the cap 24 as shown in Figure 8.

[0040] The improved safety shield assembly 23 thus provides several important advantages. First, the safety shield assembly 23 and cap 24 may be easily attached to the pen injector 20 without inadvertent retraction of the safety shield assembly 23 on the pen injector 20 and piercing the cap 24, exposing the needle cannula 34 to the patient. This safety feature is provided by the radial ribs 56 on the hub member 40, which engage the internal ribs 84 of the cap 24 preventing retraction of the shield 22 during assembly. Upon removal of the cap 24, the pen injector 20 may be easily utilized for self-injection by the patient by depressing the generally closed end 60 of the safety shield 22 against the area to be injected without ever exposing the second end 38 of the needle cannula 34 to view. Following injection, the safety shield 22 is automatically extended by the spring 74 to enclose the second end 38 of the needle cannula 34 and locked in the extended position by the resilient fingers 52 which extend into the openings 68 through the channel-shaped tracks 64. The hook-shaped fingers 52 also lock over the resilient integral tangs 70. Following use, the safety shield assembly 23 and needle cannula and hub assembly 32 may be easily removed from the pen injector 20 by unthreading the tubular rim portion 42 of the hub member 40 from the tubular end portion 44 of the pen injector 20, reversing the assembly, and inserting the first end 36 of the needle cannula 34 into the cap 24, providing for safe disposal of the assembly wherein both ends of the double ended needle cannula 34 are safely enclosed, preventing inadvertent contact with the needle cannula 34.

[0041] As set forth above, the needle cannula and hub assembly 32 is assembled in the safety shield assembly 23 prior to receipt by the end user, wherein the hook-shaped fingers 52 are releasably retained by the ledge 72 of the inwardly projecting tangs 70 during assembly of the shield 22 on the clip member 48. The cap 24 is
assembled on the shield 22 by disposing the inwardly projecting ribs 84 of the cap 24 into the slots 66 in the shield 22 as best shown in Figure 1, wherein the end portions 87 of ribs 84 engage the ends of the radial rib portions 56 as best shown in Figure 2. The radial ribs 56 include a chamfered end 57 which guides the ribs 56 into the slot 66 and the radial ribs 56 are connected to the tubular body portion by web portions 55. Further, the coil spring 74 is received between the radial ribs and the tubular body portion 50 against the web portion 55 as shown in Figure 2. The radial ribs 56 may thus be resiliently flexed inwardly during assembly. As set forth above, the clip member 48 may be formed of a resilient polymeric material, such as polypropylene or formed of a metal stamping. All of the components of the safety shield assembly 23 and the cap 24 are preferably formed of a sterilizable material including a polymeric material which can be injection molded. Thus, a suitable material for the cap 24, shield 22 and clip member 48 is a sterilizable polypropylene.

[0042] Other locking means for locking the shield 22 in the extended position following injection may be utilized. Further, locking means may be provided within the cap 24 for locking the safety shield assembly 23 within the cap 24 following removal of the safety shield assembly 23 from the pen injector 20 and storage of the assembly in the safety cap 24 as shown in Figure 8, including interlocking ribs, etc. Further, certain improved features of the safety shield system may be utilized with conventional pen needle and shield assemblies, including, for example, the radial ribs 84 on the internal surface of the cap 24 which prevent depression or retraction of the shield 22 during assembly of the safety shield 22 and cap 24 on the pen injector 20 as described above.

[0043] Referring now to Figures 9 - 15, an embodiment of the safety shield system is shown, in which, generally like numerals increased by one hundred indicate like or corresponding parts throughout the several views. Figures 9 - 11 illustrate the safety shield system per se and Figures 12 - 15 illustrate the safety shield system mounted to a pen injector 120. As shown in Figures 12 - 15, the pen injector 120 includes a body portion 121 for receiving a container 130, such as a vial 130, having fluid disposed therein.

[0044] The safety shield system includes a hub member 140 removably mounted to the body portion 121. The hub member 140 includes a tubular rim portion 142 which is preferably threadably received on a tubular end portion 144 of the pen injector 120. The hub member 140 also includes at least one radially extending rib 141 and a central portion 146 which receives and secures a needle cannula 134. In particular, the needle cannula 134 is mounted to and extends through the hub member 140. Specifically, the needle cannula 134 has a first end 136 extending into the body portion 121 for fluid communication with the container 130 and a second end 138 extending away from the body portion 121 for injection and transfer of the fluid from the container 130 to a user. As discussed above, the needle cannula 134 includes a lumen or small passage therethrough for transferring fluid in the vial 130 to the user for self-injection or administration by a health care worker.

[0045] Referring also to Figures 9-11, the safety shield 122 system includes a clip member 148 mounted to the hub member 140 and having at least one laterally projecting resilient finger 152. Preferably, the clip member 148 includes a plurality of spaced laterally projecting resilient fingers 152. Each of the resilient fingers 152 include a hook-shaped end portion. The clip member 148 may be formed of a metallic material and includes a common base 151 with each of the resilient fingers 152 extending from the base 151. The base 151 is in turn fastened to the central portion 146 of the hub member 140. Alternatively, the clip member 148 may be formed of other materials or integrally formed with the hub. The fingers 152 are able to flex inwardly and resiliently flex outwardly as described below.

[0046] A shield 122 is moveably mounted to the clip member 148 between a first position surrounding the second end 138 of the needle cannula 134, see Figures 10-13, and 15, and a second position exposing the second end 138 of the needle cannula 134, see Figure 14. The shield 122 is generally cup-shaped having an open end 158 received around the clip member 148 and a generally closed end 160 having a central opening 162 therethrough receiving the second end 138 of the needle cannula 134 as described below. The shield 122 includes at least one opening 168 and preferably a plurality of openings 168 for receiving the fingers 152. The openings 168 extend through a side wall of the shield 122 for receiving the hook-shaped end portions of the fingers 152 therethrough to lock the shield 122 in the first position surrounding the needle cannula 134 (shown in Figure 15). Each of the hook-shaped end portions of the fingers 152 preferably open toward the shield 122 for easy insertion into the openings 168. In particular, the shield 122 is first retracted to the second position to expose the needle cannula 134, see Figure 14, and then extended to the first position surrounding the needle cannula 134 where the fingers 152 now lock the shield 122 in the first position to prevent further exposure of the needle cannula 134, see Figure 15.

[0047] In this embodiment of the subject invention, each of the hook-shaped end portions of the fingers 152 are larger than the corresponding openings 168 in the shield 122 such that the resilient fingers 152 initially slide over the openings 168 when the shield 122 is retracted to the second position. In particular, the hook-shaped end portions of the fingers 152 are longer than the openings 168 in the shield 122. The openings 168 each include a chamfer 169 with the fingers 152 first engaging the chamfer 169 and then extending into the openings 168 when the shield 122 returns to the first position from the second position.

[0048] As seen, for example, in Fig. 13, the second end of the needle cannula is disposed within a channel
formed by a guide. As a result, the needle cannula is disposed within the opening 162, whether the tip of the needle is exposed or not. As the shield is retracted, the guide prevents the needle tip from catching on the portions of the shield adjacent to the opening 162.

[0049] The shield 122 further includes at least one radial groove 166 with the radially extending rib 141 of the hub member 140 being disposed within the groove 166 to prevent rotation of the shield 122 relative to the clip member 148. In the preferred embodiment, the shield 122 includes a plurality of spaced radial grooves 166 and the hub member 140 includes a plurality of spaced radially extending ribs 141 with a corresponding rib 141 disposed within each groove 166 to prevent rotation of the shield 122 relative to the clip member 148.

[0050] The safety shield 122 system further includes a spring 174 disposed within the shield 122 for continuously biasing the shield 122 toward the first position. Preferably, the spring 174 is a spiral spring having one end abutting the common base 151 and an opposed end biased against the generally closed end 160 of the shield 122.

[0051] As shown in Figures 9-12, a removable cup-shaped top cap 124 is also provided in this embodiment for initially being received over the shield 122. The top cap 124 includes an open end 178 which receives the hub member 140 as described below and a closed end 180. An internal surface of the cup-shaped top cap 124 includes inwardly projecting ribs 184 which are disposed within the grooves 166 of the shield 122. The ribs are designed to align with ribs 141 of the hub member 140 to prevent actuation during assembly. The shield 122 cannot be accessed when the top cap 124 is installed such that the shield 122 cannot retract relative to the hub member 140 when the top cap 124 is received over the shield 122. An external surface of the top cap 124 may also include ribs 182 to assist in gripping the top cap 124 during assembly of the shield system on the pen injector 120. The top cap 124 also includes first 181 and second 183 internal tabs. The first internal tabs 181 form an undercut which engages the ribs 141 of the hub member 140 to secure the top cap 124 to the hub member 140 and provide a degree of resistance during removal of the top cap 124 from the hub member 140 as described below. As shown in greater detail. As with the embodiment of Figures 1-8, one important advantage of the safety shield system is that the safety shield system may be preassembled and supplied to the patient or end user as an assembly ready for use.

[0055] The first step by the patient or end user is to break the frangible label 196 by rotating the bottom cap 193 relative to the top cap 124, see Figure 11. As mentioned above, the bottom cap 193 includes the second camming surface 197 which engages the first camming surface 185 on the top cap 124. The bottom cap 193 therefore axially separates from the top cap 124 as the bottom cap 193 is rotated thereby exposing the tubular rim portion 142 of the hub member 140 and the second end 138 of the needle cannula 134. The bottom cap 193 is then set aside for future use.

[0056] Referring to Figure 12, the hub member 140 can now be attached to the pen injector 120 by threading the tubular rim portion 142 of the hub member 140 on the tubular end portion 144 of the pen injector 120. As can be seen from Figure 12, the internal ribs 184 on the top cap 124, which are aligned with and about the ribs 141 of the hub member 140 and are disposed within the grooves 166 of the shield 122, prevent inadvertent depression or retraction of the shield 122 which could drive the second end 138 of the needle cannula 134 through the opening 168 of the shield 122 and puncture the top cap 124, which would expose the end user to the needle cannula 134. The vial 130 may be previously loaded into the pen injector 120 and the open end may be closed by an end cap (not shown), such that the threading assembly...
results in piercing the first end 136 of the needle cannula 134 through the closure, such as a rubber septum, in the open end of the vial 130. Alternatively, the vial 130 may be inserted into the pen injector 120 following assembly.

With the vial in place, the top cap 124 is removed from the assembly as shown in Figures 13-15 and set aside for future use. The safety shield system is then ready for use.

As set forth above, the safety shield system is particularly, but not exclusively, suitable for pen injectors 120 typically used for self-administration of fluid or liquid drugs, vaccines or medicament, such as insulin, anti-histamines, et cetera. During use, the patient simply depresses the generally closed end 160 of the shield 122 against a body area to be injected and actuates the pen injector. Referring to Figure 14, this depression moves the shield 122 into the second position and allows the second end 138 of the needle cannula 134 to pass through the opening 168 in the shield 122 such that this end of the needle cannula 134 can be injected into the user.

During the movement of the shield 122 to the second position, the larger fingers 152 slide over the openings 168 and are resiliently biased inwardly. Preferably, the tips 652 of the fingers are longer than the openings 168 to prevent engagement of the finger to the opening during actuation. Rotation of the shield 122 relative to the hub member 140 is prevented by the ribs 141 which follow the axial slots or grooves 166 assuring axial movement of the shield 122.

Following injection, the needle cannula 134 is withdrawn from the patient and the shield 122 is simultaneously extended by the coil spring 174, such that the second end 138 of the needle cannula 134 is never exposed. Upon full extension of the shield 122 to enclose the second end 138 of the needle cannula 134, the hook-shaped end portions of the fingers 152 engage the chambers 169 and are received through the openings 168 locking the shield 122 in the extended first position as shown in Figure 15. That is, the shield 122 cannot be retracted following injection to expose the second end 138 of the needle cannula 134.

The safety shield system may then be removed from the pen injector 120 by unthreading the tubular rim portion 142 of the hub member 140 from the threaded tubular end portion 144 of the pen injector 120 and safely disposed of directly into a sharps container. Alternatively or in addition, the top 124 and bottom 193 caps can be re-installed over the shield 122 and hub members 140 to completely and safely encompass the needle cannula 134 as shown in Figure 10. The first end 136 of the needle cannula 134 is thus safely received in the cup-shaped bottom cap 193 and the second end 138 of the needle cannula 134 is protected by the safety shield 122 and the top cap 124. The camming surfaces 197 and 185 interact to self-align the bottom cap and the top cap as they are reattached to the pen needle.

Having described the embodiments of this invention, we now claim the invention, as follows.

**Claims**

1. A safety shield system for a drug delivery device, the safety shield system comprising:

   - a hub member (140) securable to the drug delivery device (120);
   - a needle cannula (134) mounted to the hub member;
   - a clip member (148) attached to the hub member and having a laterally outwardly projecting hook shaped finger (152);
   - a shield (122) moveably mounted with respect to the hub member between a first position surrounding the needle cannula and a second position exposing the needle cannula, the shield including an opening (168) for receiving the finger when the shield is first caused to move from the first position to the second position, and then caused to move from the second position to the first position such that the finger locks the shield in the first position to prevent subsequent movement of the shield from the first position to the second position;
   - a spring (174) disposed within the shield for continuously biasing the shield toward the first position;
   - a cup-shaped top cap (124) removably surrounding the shield; and
   - a cup-shaped bottom cap (193) interconnected with the cup-shaped top and removably surrounding the hub member.

2. The safety shield system of claim 1, wherein the finger is made of a resilient material and includes a hook-shaped end portion opening toward the shield and the opening extends through a side wall of the shield for receiving the hook-shaped end portion therethrough to lock the shield in the first position surrounding the needle cannula.

3. The safety shield system of claim 1, wherein the clip member includes a plurality of spaced resilient fingers and the shield includes a plurality of corresponding openings through side walls of the shield for receiving the fingers and locking the shield in the first position surrounding the needle cannula.

4. The safety shield system of claim 3 wherein the clip member includes a common base with each of the resilient fingers extending from the base.

5. The safety shield system of claim 4 wherein the spring is a spiral spring having one end abutting the common base and an opposed end biased against...
6. The safety shield system of claim 1 wherein the needle cannula extends through the hub member to define a first end for extending into the drug delivery device to puncture a closure in a container received in the drug delivery device, and a second end extending into the shield.

7. The safety shield system of claim 6 wherein the shield is generally cup-shaped having an open end received around the clip member and a generally closed end having a central opening therethrough receiving the second end of the needle cannula, and the spring being a spiral spring biased against the generally closed end of the shield.

8. The safety shield system of claim 1 wherein the finger includes a hook-shaped end portion which is larger than the opening in the shield such that the resilient finger initially slides over the opening when the shield is retracted to the second position.

9. The safety shield system of claim 8 wherein the opening includes a chamfer with the finger first engaging the chamfer and then extending into the opening when the shield returns to the first position from the second position.

10. The safety shield system of claim 8 wherein the shield includes at least one radial groove and the hub member includes at least one radially extending rib disposed within the groove to prevent rotation of the shield relative to the clip member.

11. The safety shield system of claim 8 wherein the shield includes a plurality of spaced radial grooves and the hub member includes a plurality of spaced radially extending ribs with a corresponding rib disposed within each groove to prevent rotation of the shield relative to the clip member.

12. The safety shield system as of claim 1 wherein the cup-shaped top cap includes inwardly projecting ribs which are disposed within the grooves of the shield for preventing retraction of the shield relative to the hub member when the top cap is received over the shield.

13. The safety shield system of claim 12 wherein the top cap includes at least one first internal tab which engages the ribs of the hub member to secure the top cap to the hub member and provide a degree of resistance during removal of the top cap from the hub member.

14. The safety shield system of claim 1 wherein the bottom cap interengages the top cap when the top cap is received over the shield and the bottom cap is received over the hub member thereby forming a sterile barrier.

15. The safety shield system of claim 14 wherein the top cap includes at least one second internal tab which engages the bottom cap to secure the bottom cap to the top cap and provide a degree of resistance during removal of the bottom cap from the top cap.

16. The safety shield system of claim 14 wherein the top cap includes a first camming surface and the bottom cap includes a second camming surface with the first and second camming surfaces abutting each other during rotation of the bottom cap relative to the top cap such that the bottom cap simultaneously moves axially away from the top cap.

17. The safety shield system of claim 1, further comprising a pen-type drug delivery device to which the hub member may be secured.

18. The safety shield system of claim 1, further comprising a guide disposed in the shield and forming a channel, wherein, when the shield is in the first position and in the second position, the needle cannula is, at least in part, within the channel.

19. The safety shield system of claim 1, wherein the clip member is integrally formed with the hub.

Patentansprüche

1. Sicherheits-Schutzsystem für eine Medikamentenzuführvorrichtung, mit:

   einem Ansatzteil (140), das an der Medikamentenzuführvorrichtung (120) befestigbar ist;
   einer Nadelkanüle (134), die an dem Ansatzteil befestigt ist;
   einem Cliquenteil (148), das an dem Ansatzteil befestigt ist und einen seitlich nach außen absteckenden hakenförmigen Finger (152) aufweist;
   einem Schutzein (122), das relativ zu dem Ansatzteil zwischen einer ersten Position, in der es die Nadelkanüle umgibt, und einer zweiten Position bewegbar ist, in der die Nadelkanüle exponiert ist, wobei das Schutzein eine Öffnung (168) aufweist, die, wenn das Schutzein das erste Mal aus der ersten Position in die zweite Position bewegt wird und dann aus der zweiten Position in die erste Position bewegt wird, den Finger derart aufnimmt, dass der Finger das Schutzein in der ersten Position verriegelt, um eine nachfolgende Bewegung des Schutzeins aus der ersten Position in die zweite Position zu verhindern;
2. Sicherheits-Schutzsystem nach Anspruch 1, bei dem der Finger aus einem elastischen Material ausgebildet ist und einen hakenförmigen Endteil aufweist, der sich zu dem Schutzteil hin öffnet, und die Öffnung durch eine Seitenwand des Schutzteils verläuft, um das Schutzteil abnehmbar umzugeben, und dadurch das Schutzteil in der die Nadelkanüle umgebenden ersten Position zu verriegeln.

4. Sicherheits-Schutzsystem nach Anspruch 3, bei dem das Clipteil eine gemeinsame Basis aufweist, wobei jeder der elastischen Finger von der Basis absteht.

5. Sicherheits-Schutzsystem nach Anspruch 4, bei dem die Feder eine Spiralfeder ist, die mit einem Ende an der gemeinsamen Basis anliegt und mit dem gegenüberliegenden Ende gegen das Schutzteil vorgespansnt ist.

6. Sicherheits-Schutzsystem nach Anspruch 1, bei dem die Nadelkanüle derart durch das Ansatzteil verläuft, dass ein erstes Ende, welches sich in die Medikamentenzuführvorrichtung erstreckt, ein entsprechender Öffnung aufweist, um ein Verschlussstück eines in der Medikamentenzuführvorrichtung aufgenommenen Behälters zu punktieren, und ein zweites Ende gebildet wird, das sich in das Schutzteil erstreckt.

7. Sicherheits-Schutzsystem nach Anspruch 6, bei dem das Schutzteil im Wesentlichen becherförmig ist und ein offenes Ende, das das Clipteil umgibt, und ein im Wesentlichen geschlossenes Ende mit einer durch dieses verlaufenden zentralen Öffnung aufweist, die das zweite Ende der Nadelkanüle aufnimmt, wobei die Feder eine Spiralfeder ist, die gegen das im Wesentlichen geschlossene Ende des Schutzteils vorgespansnt ist.

8. Sicherheits-Schutzsystem nach Anspruch 1, bei dem der Finger ein hakenförmiges Ende aufweist, das derart größer ist als die im Schutzteil ausgebildete Öffnung, dass der elastische Finger anfangs über die Öffnung gleitet, wenn das Schutzteil in die zweite Position zurückgezogen wird.

9. Sicherheits-Schutzsystem nach Anspruch 8, bei dem die Öffnung eine Schräüng aufweist, wobei der Finger zuerst an der Schräüng angreift und sich dann in die Öffnung bewegt, wenn das Schutzteil aus der zweiten Position in die erste Position zurückkehrt.

10. Sicherheits-Schutzsystem nach Anspruch 8, bei dem das Schutzteil mindestens eine Radialnuten aufweist und das Ansatzteil mindestens eine radial verlaufende Rippen aufweist, die in der Nut angeordnet ist, um eine Drehung des Schutzteils relativ zu dem Clipteil zu verhindern.

11. Sicherheits-Schutzsystem nach Anspruch 8, bei dem das Schutzteil mehrere mit gegenseitigem Abstand angeordneten Radialnuten aufweist und das Ansatzteil mehrere mit gegenseitigem Abstand angeordnete, radial verlaufende Rippen aufweist, wobei in jeder Nut eine entsprechende Rippe angeordnet ist, um eine Drehung des Schutzteils relativ zu dem Clipteil zu verhindern.

12. Sicherheits-Schutzsystem nach Anspruch 1, bei dem die becherförmige obere Kappe nach innen vorspringende Rippen aufweist, die in den Nuten des Schutzteils angeordnet sind, um ein Zurückziehen des Schutzteils relativ zu dem Ansatzteil zu verhindern, wenn die obere Kappe auf das Schutzteil gesetzt ist.

14. Sicherheits-Schutzsystem nach Anspruch 1, bei dem die untere Kappe mit der oberen Kappe zusammengreift, wenn die obere Kappe auf dem Schutzteil sitzt, und die untere Kappe auf dem Ansatzteil sitzt, um eine sterile Barriere zu bilden.

15. Sicherheits-Schutzsystem nach Anspruch 14, bei dem die obere Kappe mindestens einen zweiten inneren Vorsprung aufweist, der mit der unteren Kappe zusammengreift, um die untere Kappe an der oberen Kappe zu sichern und beim Abnehmen der unteren Kappe von der oberen Kappe ein Maß an Widerstand zu erzeugen.
16. Système de protection de sécurité selon la revendication 14, dans lequel le doigt comporte une partie élastique s'étendant depuis la base jusqu'à la première position entourant la canule en aiguille.

17. Système de protection de sécurité selon la revendication 1, dans lequel le doigt est fait à partir d'un matériau résilient et comporte une portion d'extrémité en crochet s'appuyant sur la paroi latérale de la protection pour recevoir les doigts et verrouiller la protection dans la première position entourant la canule en aiguille.

18. Système de protection de sécurité selon la revendication 1, dans lequel le doigt est fait à partir d'un matériau résilient et comporte une portion d'extrémité en crochet s'appuyant sur la paroi latérale de la protection pour recevoir les doigts et verrouiller la protection dans la première position entourant la canule en aiguille.

19. Système de protection de sécurité selon la revendication 1, dans lequel le doigt est fait à partir d'un matériau résilient et comporte une portion d'extrémité en crochet s'appuyant sur la paroi latérale de la protection pour recevoir les doigts et verrouiller la protection dans la première position entourant la canule en aiguille.

Revendications

1. Système de protection de sécurité pour un dispositif d'administration de médicaments, le système de protection de sécurité comprenant :

- un élément formant moyeu (140) pouvant être bloqué sur le dispositif d'administration de médicaments (120) ;
- une canule en aiguille (134) montée sur l'élément formant moyeu ;
- un élément formant pince (148) attaché sur l'élément formant moyeu et ayant un doigt (152) en crochet faisant saillie latéralement vers l'extérieur ;
- une protection (122) montée de manière déplacable par rapport à l'élément formant moyen entre une première position entourant la canule en aiguille et une seconde position exposant la canule en aiguille, la protection comportant une ouverture (168) destinée à recevoir le doigt lorsque la protection est d'abord amenée à se déplacer depuis la première position jusqu'à la seconde position, et ensuite amener à se déplacer depuis la seconde position jusqu'à la première position, de telle manière que le doigt verrouille la protection dans la première position afin d'empêcher un déplacement ultérieur de la protection depuis la première position vers la seconde position ;
- un ressort (174) disposé à l'intérieur de la protection pour dévier de manière continue la protection vers la première position ;
- un embout supérieur (124) en forme de coupe entourant la protection ; et
- un embout inférieur (193) en forme de coupe relié au haut en forme de coupe et entourant de manière amovible l'élément formant moyeu.

2. Système de protection de sécurité selon la revendication 1, dans lequel le doigt est fait à partir d'un matériau résilient et comporte une portion d'extrémité en crochet s'appuyant sur la protection et l'ouverture s'étend au travers d'une paroi latérale de la protection pour recevoir la portion d'extrémité en crochet au travers de celle-ci afin de verrouiller la protection dans la première position entourant la canule en aiguille.

3. Système de protection de sécurité selon la revendication 1, dans lequel l'élément formant pince comporte une pluralité de doigts résiliants espacés et la protection comporte une pluralité d'ouvertures correspondantes au travers de parois latérales de la protection destinées à recevoir les doigts et verrouiller la protection dans la première position entourant la canule en aiguille.

4. Système de protection de sécurité selon la revendication 3, dans lequel l'élément formant pince comporte une base commune avec chacun des doigts résiliants s'étendant depuis la base.

5. Système de protection de sécurité selon la revendication 4, dans lequel le ressort est un ressort en spirale ayant une extrémité s'appuyant sur la base commune et une extrémité opposée déviée contre la protection.

6. Système de protection de sécurité selon la revendication 1, dans lequel la canule en aiguille s'étend au travers de l'élément formant moyeu afin de définir une extrémité générale pour s'étendre dans le dispositif d'administration de médicaments pour recevoir un élément de fermeture dans un récipient reçu dans le dispositif d'administration de médicaments, et une seconde extrémité s'étendant dans la protection.

7. Système de protection de sécurité selon la revendication 6, dans lequel la protection est généralement en forme de coupe ayant une extrémité ouverte recevant la première extrémité généralement fermée ayant une ouverture centrale au travers de celle-ci, recevant la seconde extrémité de la canule en aiguille, et le ressort étant un ressort en spirale dévié contre l'extrémité généralement fermée de la protection.

8. Système de protection de sécurité selon la revendication 1, dans lequel le doigt comporte une portion
d’extrémité en crochet qui est plus grande que l’ouverture de la protection, de telle manière que le doigt résilient coulisse initialement au-dessus de l’ouverture lorsque la protection est reculée vers la seconde position.

9. Système de protection de sécurité selon la revendication 8, dans lequel l’ouverture comporte un chanfrein, le doigt mettant d’abord en prise le chanfrein et s’étendant ensuite dans l’ouverture lorsque la protection retourne vers la première position depuis la seconde position.

10. Système de protection de sécurité selon la revendication 8, dans lequel la protection comporte au moins une rainure radiale et l’élément formant moyeu comporte au moins une nervure s’étendant radialement disposée à l’intérieur de la rainure afin d’empêcher une rotation de la protection relativement à l’élément formant pince.

11. Système de protection de sécurité selon la revendication 8, dans lequel la protection comporte une pluralité de rainures radiales espacées et l’élément formant moyeu comporte une pluralité de nervures es-pacées s’étendant radialement avec une nervure correspondante disposée à l’intérieur de chaque rainure afin d’empêcher une rotation de la protection relativement à l’élément formant pince.

12. Système de protection de sécurité selon la revendication 1, dans lequel l’embout supérieur en forme de coupe comporte des nervures en saillie vers l’intérieur qui sont disposées à l’intérieur des rainures de la protection pour empêcher un recul de la protection relativement à l’élément formant moyeu lorsque l’embout supérieur est reçu au-dessus de la protection.

13. Système de protection de sécurité selon la revendication 12, dans lequel l’embout supérieur comporte au moins une première languette interne qui met en prise les nervures de l’élément formant moyeu afin de bloquer l’embout supérieur sur l’élément formant moyeu et fournir un degré de résistance au cours d’un retrait de l’embout supérieur de l’élément formant moyeu.

14. Système de protection de sécurité selon la revendication 1, dans lequel l’embout inférieur met en prise réciproquement l’embout supérieur lorsque l’embout supérieur est reçu au-dessus de la protection et que l’embout inférieur est reçu au-dessus de l’élément formant moyeu, formant de ce fait une barrière stéristile.

15. Système de protection de sécurité selon la revendication 14, dans lequel l’embout supérieur comporte au moins une seconde languette interne qui met en prise l’embout inférieur afin de bloquer l’embout inférieur sur l’embout supérieur et fournir un degré de résistance au cours d’un retrait de l’embout inférieur depuis l’embout supérieur.
