Note: Within nine months of the publication of the mention of the grant of the European patent in the European Patent Bulletin, any person may give notice to the European Patent Office of opposition to that patent, in accordance with the Implementing Regulations. Notice of opposition shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

Field of the Invention

[0001] This invention relates to apparatus for releasing tablets from a blister pack having a plurality of tablets contained in corresponding blisters.

Background of the Invention

[0002] It is common for various types of medicament to be supplied in tablet form in blister packs. Such a pack typically comprises a matrix array of blisters, each of which contains a respective tablet, which are sealed by a common foil seal across one face of the pack. In order to release a tablet from its blister, a sufficient collapsing force is to be applied to the blister to cause the tablet therein to rupture the portion of foil which seals that blister.

[0003] Although an able bodied person can relatively easily release a tablet, someone of reduced manual dexterity can find it difficult to apply a sufficient collapsing force to the blister. US5791513 shows a device which, in essence, acts as a stamp for ejecting a tablet from a blister pack. While such a device will help a person of reduced manual dexterity, it can still be awkward to use since the user has to ensure that the blister pack faces a correct position in the device with the blister containing a tablet to be ejected in registry with the appropriate portion of the stamp.

[0004] It is also known to provide devices in which a blister back is held within a housing that also has a plurality of stamps, each in registry with a respective blister, or a single stamp which can move from one blister to another. Such designs are, however, still relatively complex (and therefore expensive to produce), and can also still be awkward to use.

[0005] DE3317549 shows apparatus according to the pre-characterising portion of claim 1.

Summary of the Invention

[0006] According to the invention, there is provided apparatus for releasing tablets from a blister pack having a plurality of tablets contained in corresponding blisters, the apparatus comprising abutment means, receiving means comprising a pair of opposed jaws for receiving a blister pack with any selected one of a plurality of blisters of the pack in registry with the abutment means, either one of the abutment means and the receiving means being moveable to cause a collapsing force to be exerted on a selected blister thereby to release a tablet from the blister, wherein the apparatus includes biasing means integrally formed with a jaw for urging the receiving means into engagement with the blister pack, and the receiving means so arranged that said engagement releasably retains, and locates, the blister pack in position relative to the abutment means prior to the release of the tablet, characterised in that the biasing means comprise a resiliently flexible substantially u-shaped connecting arm.

[0007] By locating the blister pack, the receiving means helps the user correctly to position a blister pack relative to the abutment means. The receiving means also avoids the need for the user to hold the blister pack in a precise position relative to the abutment means.

[0008] Preferably, the abutment means is moveable towards a blister of a pack retained in the receiving means.

[0009] Preferably, the receiving means is arranged to receive a blister pack so that the selected blister faces the abutment means, the latter being operable to exert said collapsing force by directly engaging the blister.

[0010] One of those jaws may conveniently be so shaped as to locate a selected blister in registry with the abutment means, and to that end may have a recess, of a complimentary shape to that of a blister.

[0011] The abutment means may be incorporated into the receiving means, but preferably comprises a plunger movably mounted on a jaw on the receiving means.

[0012] Such an arrangement can simplify the construction, and hence reduce the production costs, of the apparatus.

[0013] Preferably, the biasing means biases the jaws into a neutral position, in which they are spaced apart so as to be able to receive a blister pack. This spacing allows the user to move the jaws against the action of the biasing means simply by inserting a blister pack into the space between the jaws.

[0014] The apparatus may advantageously include a further biasing means which acts between the plunger and the jaw in which it is mounted so as to urge the plunger away from the other jaw.

[0015] The further biasing means is preferably arranged to exert a sufficient biasing force on the plunger to make it difficult for a small child to use the device to obtain a tablet, whilst not significantly detracting from the facility that the device provides for its intended user.

[0016] Preferably, the further biasing means comprises a resiliently compressible member.

[0017] Such a member conveniently comprises a sleeve which extends around the plunger.

[0018] Preferably, the apparatus includes a base for supporting the jaws on a supporting surface, the base including an opening and a chute for conducting a tablet release from a blister pack to the opening. Another advantages associated with the apparatus is that the plunger can have a head, to be pressed by the user, which is considerably larger than a blister, since the need to provide a respective abutment for each blister is avoided by having receiving means which can receive a blister pack in any one of a number of possible positions, in each of which a respective blister is in registry with the plunger.
Brief Description of the Drawings

[0019] The invention will now be described, by way of example only, with reference to the accompanying drawings in which:

Figure 1 is an isometric view of apparatus in accordance with the invention and a blister pack for use therewith;

Figure 1a is a sectional side view of the apparatus and blister pack of Figure 1;

Figures 3-6 are views, corresponding to Figure 1, of the apparatus and blister pack during various stages in the operation of the apparatus;

Figures 3a-6a are views, similar to Figure 1a, at each of the stages shown in Figures 3-6 respectively; and

Figure 7 is a sectional view, corresponding to Figure 1a, of a second embodiment of apparatus in accordance with the invention.

Detailed Description

[0020] The apparatus in accordance with the invention comprises a base one which has a circular edge and a domed underside (referenced to in Figure 1a). A hollow circularly cylindrical column 4 extends upwardly from the centre of base 1 and incorporates an internal sloped chute 6 the bottom of which is situated adjacent an arcuate peripheral wall 8 on the base 1. The top surface 10 of the column 4 constitutes the lower jaw of the receiving means of the apparatus and also defines a central aperture 12 through which a tablet released by the apparatus can fall into the chute 6 and hence to the wall 8.

[0021] A generally U-shaped arm has one end formed integrally with the lower jaw 10, and extends naturally away from the lower jaw 10. The other end of the arm 14 carries an upper jaw 16 positioned immediately above the lower jaw 10, but spaced from the latter so as to define an opening between the two jaws. The arm 14 has two identical straight portions, one of which is shown at 18, connected together by a curved portion 20 of reduced thickness. The second straight portion of the arm 14 is shown at 19 in Figure 1a. The arm 14 is resiliently flexible in particularly the region of portion 20 so as to bias the upper jaw 16 into the position shown in Figure 1a.

[0022] The front of the jaw 16 is provided with a curved recess 22 having a front downwardly facing chamber 24 that acts as a camming surface.

[0023] The underside of the jaw 16 also includes a central recess 26 which is tapered, and in use locates a blister from the blister pack 3.

[0024] A hollow cylindrical stem 28 extends upwardly from the recess 26, and locates a plunger 30 which is mounted so as to be slidable through the stem 28. A generally circular push button 32 extends radially outwards from the top of the plunger 30, and is formed integrally therewith. The base 1, column 4, arm 14 and jaws are all formed as a single integral unit of a suitable plastic material.

[0025] The top of the jaw 16 also includes a circular peripheral wall 34 which, with the stem 28, defines an annular channel in the top of the jaw 16. This channel accommodates the bottom end of a resiliently compressible metal, plastics or foam spring. In this particular example, the spring is a cylinder 36 of a resiliently compressible foam material, the top of which acts directly on the underside of the button 32.

[0026] The blister pack 3, in this example, comprises 2 parallel rows, each of 5 blisters, in each of which a respective single tablet. These tablets are held in position by a sheet of heat sealed foil 38 on the underside of the pack 3.

[0027] When a tablet is to be released from a given blister, for example the blister 40, the pack 3 is positioned with the blister 40 in alignment with the recess 22 in the upper jaw 16. The blister 40 is then moved directly towards the recess 22 until it engages the camming surface 24. The height of the blister is slightly greater than the distance between the two jaws at the recess 12, and the engagement of the blister 40 with the camming surface 24 therefore tends to urge the two jaws apart so as to allow the blister 40 to be inserted into disposed between the jaws. As a blister approaches the recess 34, the biasing provided by the arm 14 causes the blister to be gently squeezed by the jaws and thereby to be urged into the recess 34. Thus the two jaws, operating in conjunction with the arm 14, will locate and retain the blister 40 into position in registry with the plunger 30.

[0028] This position is shown in Figures 3 and 3a.

[0029] Referring to Figures 4 and 4a, the user then presses on the button 32 and thus urges the plunger 30 against the top of the blister 40. Since the button 32 has a much larger area than the underside of the plunger 30, a given pressure exerted evenly to the button 32 will cause the plunger 30 to exert a much larger pressure on the blister 40. This helps the user to exert a sufficient force on the blister 40 to rupture the portion of the foil which seals that blister and thus to allow the tablet (reference 41) previously in the blister 40 to fall from the bottom of the pack, through the opening 12 and on to the chute 16, which then conveys the tablet 41 to the front of the base, to the position shown in Figures 4 and 4a, in which the tablet rests against wall 8.

[0030] The user the releases button 32 causing the plunger 30 to be urged upwardly by the sleeve 36 into the position shown in Figure 5 and 5a, and thus to enable the blister pack to be removed as shown in Figures 6 and 6a. The user can then easily retrieve the tablet 41 from the front of the base 1.

[0031] If the next tablet 44 is to be released from the blister 45, the pack 3 is moved until the blister 45 is alignment with the recess 12 and the process is repeated.
Once all the blisters have been released from the first of the rows 5 and 7 the pack is re-orientated so that the second of those rows is closer to the apparatus.

It will be appreciated from the forgoing that the apparatus functions in a similar fashion to a ticket stamp.

With reference to Figure 7 the second embodiment is similar in many respects to the first embodiment, and the reference numeral used in Figure 1a are also used to denote the corresponding parts of the second embodiment. In the second embodiment the foam spring 36 is assisted by a helical spring 100 of metal, plastics or similar material.

In a modified version of the second embodiment, a sleeve of a resiliently compressible material other than foam replaces the sleeve 36.

**Claims**

1. Apparatus for releasing tablets (41, 44) from a blister pack (3) having a plurality of tablets (41, 44) contained in corresponding blisters (40, 45), the apparatus comprising abutment means (30), receiving means (10, 16) comprising a pair of opposed jaws (10, 16) for receiving a blister pack (3) with any selected one of a plurality of blisters (40, 45) of the pack in registry with the abutment means (30), either one of the abutment means (30) and the receiving means (10, 16) being moveable to cause a collapsing force to be exerted on a selected blister (40, 45) thereby to release a tablet (41, 44) from the blister, wherein the apparatus includes biasing means (14, 18, 19, 20) integrally formed with a jaw (10, 16) for urging the receiving means (10, 16) into engagement with the blister pack (3), and the receiving means (10, 16) is so arranged that said engagement releasably retains, and locates, the blister pack (3) in position relative to the abutment means (30) prior to the release of the tablet (41, 44), characterised in that the biasing means (14, 18, 19, 20) comprise a resiliently flexible substantially u-shaped connecting arm (18, 19, 20).

2. Apparatus according to claim 1, wherein the abutment means (30) is moveable towards a blister (40, 45) of a pack (3) retained in the receiving means (10, 16).

3. Apparatus according to claim 1 or 2, wherein the receiving means (10, 16) is arranged to receive a blister pack (3) so that the selected blister (40, 45) faces the abutment means (30), the latter (30) being operable to exert said collapsing force by directly engaging the blister (40, 45).

4. Apparatus according to any preceding claim, wherein one of the jaws (16) is so shaped as to locate a selected blister (40, 45) in registry with the abutment means (30), and has a recess (26) of a complimentary shape to that of a blister (40, 45).

5. Apparatus according to any preceding claim, wherein in the abutment means (30) comprises a plunger (30) moveably mounted on a jaw (16) of the receiving means (10, 16).

6. Apparatus according to any preceding claim, wherein in the biasing means (14, 18, 19, 20) are operable to bias the jaws (10, 16) into a neutral position, in which they are spaced apart so as to be able to receive a blister pack (3).

7. Apparatus according to claim 5 or claim 6 when dependent therefrom, wherein the apparatus includes a further biasing means (36, 100) which acts between the plunger (30) and the jaw (16) in which it is mounted so as to urge the plunger (30) away from the other jaw (10).

8. Apparatus according to claim 7, wherein the further biasing means (36, 100) is arranged to exert a sufficient biasing force on the plunger (30) so as to make it difficult for a small child to use the device to obtain a tablet (41, 44).

9. Apparatus according to claim 7 or 8, wherein the further biasing means (36, 100) comprises a resiliently compressible member (36, 100).

10. Apparatus according to claim 9, wherein the resiliently compressible member (36, 100) comprises a sleeve (36) which extends around the plunger (30).

11. Apparatus according to any preceding claim, wherein in the apparatus includes a base (1) for supporting the jaws (10, 16) on a supporting surface, the base (1) including an opening and a chute (16) for conducting a tablet (41, 44) released from a blister pack (3) to the opening.

12. Apparatus according to claim 5 or any claim dependent therefrom, wherein the plunger (30) has a head (32), to be pressed by the user, which is considerably larger than a blister (41, 44).

**Patentansprüche**

1. Gerät zur Freigabe von Tabletten (41, 44) aus einer Blisterpackung (3) mit mehreren Tabletten (41, 44), die in entsprechenden Blistern (40, 45) enthalten sind, wobei das Gerät ein Anschlagmittel (30) und ein Aufnahmemittel (10, 16) mit einem Paar gegen-
überliegender Backen (10, 16) zur Aufnahme einer Blisterpackung (3) aufweist, wobei ein beliebig gewählter von mehreren Blistern (40, 45) der Packung mit dem Anschlagmittel (30) registerhaltig ist, wobei das Anschlagmittel (30) oder das Aufnahmemittel (10, 16) bewegt werden kann, um zu bewirken, dass eine Eindrückkraft auf einen gewählten Blister (40, 45) ausgeübt wird, wodurch eine Tablette (41, 44) aus dem Blister freigegeben wird, wobei das Gerät einstückig mit einer Backe (10, 16) ausgebildete Vorspannmittel (14, 18, 19, 20) aufweist, um das Aufnahmemittel (10, 16) in Eingriff mit der Blisterpackung (3) zu drängen, wobei das Aufnahmemittel (10, 16) so angeordnet ist, dass die Blisterpackung (3) gehalten und positioniert wird, dadurch gekennzeichnet, dass die Vorspannmittel (14, 18, 19, 20) einen federnd flexiblen, im Wesentlichen u-förmigen Verbindungsarm (18, 19, 20) umfassen.

2. Gerät nach Anspruch 1, wobei das Anschlagmittel (30) zu einem Blister (40, 45) einer im Aufnahmemittel (10, 16) gehaltenen Packung (3) bewegt werden kann.

3. Gerät nach Anspruch 1 oder 2, wobei das Aufnahmemittel (10, 16) so zur Aufnahme einer Blisterpackung (3) angeordnet ist, dass der gewählte Blister (40, 45) dem Anschlagmittel (30) gegenüberliegt, das so bedient werden kann, dass es die Eindrückkraft ausübt, indem es den Blister (40, 45) direkt in Eingriff nimmt.

4. Gerät nach einem der vorhergehenden Ansprüche, wobei eine der Backen (16) so geformt ist, dass sie einen gewählten Blister (40, 45) registerhaltig mit dem Anschlagmittel (30) positioniert, und eine Ausnehmung (26) mit einer Form hat, die komplementär zu der eines Blisters (40, 45) ist.

5. Gerät nach einem der vorhergehenden Ansprüche, wobei das Anschlagmittel (30) einen Stößel (30) aufweist, der beweglich an einer Backe (16) des Aufnahmemittels (10, 16) montiert ist.

6. Gerät nach einem der vorhergehenden Ansprüche, wobei die Vorspannmittel (14, 18, 19, 20) so betätigt werden können, dass sie die Backen (10, 16) in einer neutralen Position vorspannen, in der sie befestet sind, damit sie eine Blisterpackung (3) aufnehmen können.

7. Gerät nach Anspruch 5 oder Anspruch 6, wenn dieser davon abhängig ist, wobei das Gerät ein weiteres Vorspannmittel (36, 100) aufweist, das zwischen dem Stößel (30) und der Backe (16), in der es montiert ist, wirkt, um den Stößel (30) von der anderen Backe (10) weg zu drängen.

8. Gerät nach Anspruch 7, wobei das weitere Vorspannmittel (36, 100) so angeordnet ist, dass es eine ausreichende Vorspannkraft auf den Stößel (30) ausübt, so dass es für ein Kleinkind schwierig ist, das Gerät zum Erhalt einer Tablette (41, 44) zu verwenden.

9. Gerät nach Anspruch 7 oder 8, wobei das weitere Vorspannmittel (36, 100) ein federnd zusammenrückbares Element (36, 100) umfasst.

10. Gerät nach Anspruch 9, wobei das federnd zusammenrückbare Element (36, 100) eine sich um den Stößel (30) erstreckende Hülse (36) umfasst.

11. Gerät nach einem der vorhergehenden Ansprüche, wobei das Gerät eine Basis (1) zum Stützen der Backen (10, 16) auf einer Stützfläche aufweist, wobei die Basis (1) eine Öffnung und eine Rutsche (16) aufweist, um eine aus einer Blisterpackung (3) freigegebene Tablette (41, 44) zur Öffnung zu führen.

Revendications

1. Appareil permettant de sortir des comprimés (41, 44) d’un emballage sous coque (3) ayant une pluralité de comprimés (41, 44) contenus dans des coques correspondantes (40, 45), l’appareil comprenant un moyen de butée (30), un moyen de réception (10, 16) comprenant une paire de mâchoires opposées (10, 16) destinées à recevoir un emballage sous coque (3) avec n’importe laquelle d’une pluralité de coques (40, 45) de l’emballage en alignement avec le moyen de butée (30), n’importe lequel du moyen de butée (30) et du moyen de réception (10, 16) étant mobile afin d’exercer une force d’écrasement sur une coque sélectionnée (40, 45) de façon à faire sortir un comprimé (41, 44) de la coque, dans lequel l’appareil comprend un moyen d’inclinaison (14, 18, 19, 20) intégralement formé avec une mâchoire (10, 16) afin de forcer le moyen de réception (10, 16) en engagement avec l’emballage sous coque (3), et le moyen de réception (10, 16) est agencé afin que leled engagement retienne de manière amovible, et place, l’emballage sous coque (3) dans une certaine position par rapport au moyen de butée (30) avant la sortie du comprimé (41, 44), caractérisé en ce que le moyen d’inclinaison (14, 18, 19, 20) comprend un bras de liaison flexible de manière élastique et sensiblement en forme de U (18, 19, 20).
2. Appareil selon la revendication 1, dans lequel le moyen de butée (30) peut se déplacer vers une coque (40, 45) d’un emballage (3) maintenu dans le moyen de réception (10, 16).

3. Appareil selon la revendication 1 ou 2, dans lequel le moyen de réception (10, 16) est agencé afin de recevoir un emballage sous coque (3) afin que la coque sélectionnée (40, 45) soit tournée vers le moyen de butée (30), ce dernier (30) pouvant exercer ladite force d’écrasement en engageant directement la coque (40, 45).

4. Appareil selon l’une quelconque des revendications précédentes, dans lequel l’une des mâchoires (16) est formée de façon à placer une coque sélectionnée (40, 45) en alignement avec le moyen de butée (30), et possède un renfoncement (26) ayant une forme complémentaire à celle d’une coque (40, 45).

5. Appareil selon l’une quelconque des revendications précédentes, dans lequel le moyen de butée (30) comprend un piston plongeur (30) monté de manière mobile sur une mâchoire (16) du moyen de réception (10, 16).

6. Appareil selon l’une quelconque des revendications précédentes, dans lequel le moyen d’inclinaison (14, 18, 19, 20) peut incliner les mâchoires (10, 16) dans une position neutre, dans laquelle elles sont espacées de façon à pouvoir recevoir un emballage sous coque (3).

7. Appareil selon la revendication 5 ou la revendication 6 lorsqu’elle dépend de celle-ci, dans lequel l’appareil comprend un autre moyen d’inclinaison (36, 100) qui agit entre le piston plongeur (30) et la mâchoire (16) dans laquelle il est monté de façon à éloigner le piston plongeur (30) de l’autre mâchoire (10).

8. Appareil selon la revendication 7, dans lequel l’autre moyen d’inclinaison (36, 100) est agencé afin d’exercer une force d’inclinaison suffisante sur le piston plongeur (30) de façon à ce qu’un enfant ne puisse pas utiliser le dispositif afin d’obtenir un comprimé (41, 44).

9. Appareil selon la revendication 7 ou 8, dans lequel l’autre moyen d’inclinaison (36, 100) comprend un élément compressible de manière élastique (36, 100).

10. Appareil selon la revendication 9, dans lequel l’élément compressible de manière élastique (36, 100) comprend un manchon (36) qui s’étend autour du piston plongeur (30).

11. Appareil selon l’une quelconque des revendications précédentes, dans lequel l’appareil comprend une base (1) destinée à supporter les mâchoires (10, 16) sur une surface de support, la base (1) comprenant une ouverture et une goulote (16) destinée à guider un comprimé (41, 44) sorti d’un emballage sous coque (3) vers l’ouverture.

12. Appareil selon la revendication 5 ou n’importe quelle revendication dépendant de celle-ci, dans lequel le piston plongeur (30) possède une tête (32), devant être enfoncée par l’utilisateur, qui est bien plus grande qu’une coque (41, 44).
