Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
The invention relates to a heat-sealed, heat-sterilised product package made of a polymer-coated, fibre-based packaging material. The invention also relates to a packaging material suitable for such a package and to the use of the material.

There are numerous known applications of polymer-coated fibre-based packaging materials, in which one or both sides of the fibre base are provided with one or more successive coating layers and which are intended for various packaging purposes. The coating can optionally achieve a moisture, oxygen and/or light barrier, which is intended to improve the storage life of the packaged product and thus to extend its effective storage and/or "best before date". The coating also provides a heat-sealable material, enabling a tight seal of the product package. Food packages constitute one principal field of application for such packaging materials, which are used for instance for cartons, casings and boxes formed of coated packaging board and pouch packages formed of coated paper.

Heat-sterilised packages form a notable group of sealed food packages, the packaging material of these being required to withstand sterilising treatment conditions. Sterilisation may be performed by irradiation or by hot pressurised steam in an autoclave. Closed metal cans have typically been treated in autoclaves, however, nowadays also fibre-based packaging materials are available for autoclave applications. WO 02/28637 thus describes a packaging material for autoclave packages, in which the board substrate is equipped with an oxygen barrier layer, polymer heat-sealing layers and binder layers required between these. In this publication, the oxygen barrier layer is preferably formed of an aluminium foil, even though EVOH is also mentioned as an optional material. The proposed material for the binder and heat-sealing layers is polypropene, which resists, without melting, the temperature above 130 °C prevailing in an autoclave.

In tests of heat-sterilised fibre-based food packages, the applicant has found the problem of bleached packaging board coated merely with polymer oxygen-barrier and heat-sealing layers tending to yellow due to heating. This is especially true for packages treated in autoclaves, which are required to resist the high autoclave temperature and pressure over the required treatment period, about 30 minutes in general. In other words, a package made of polymer-coated board gets another appearance during autoclave treatment, and this is a drawback in the market, especially in demanding applications.

The purpose of the present invention is to eliminate the problem mentioned above and to provide a sterile package made of a fibre-based material, whose material in addition to the fibre base comprises only polymer coating layers, which achieve the sealability, heat resistance and light shield required for the product, and in which also yellowing of the material as a result of heating treatment has been substantially avoided. The product package of the invention is characterised by the fact that a first polymer coating layer outside the fibre base of the package contains a white pigment, and in that the second polymer coating layer inside the first layer contains a light-absorbing pigment.

In the package of the invention, white pigment is used to hide the fibre base so that yellowing caused by heating does not significantly affect the aspect of the package, more precisely its ISO brightness. The light absorbent pigment, in turn, which has been placed in a coating layer different from that of the white pigment imparting the package its brightness, shields the packaged product from visible light. In addition, in accordance with the invention, light-absorbing black pigment can also be used as an agent for stabilising the light appearance of the package as described in the following.

In accordance with the invention, without the use of an aluminium foil, a fibre-based packaging material has thus been achieved, which resists heat sterilisation, especially autoclave treatment at high temperature and under vapour pressure, the polymer coating layers in the material forming the light shield required for the storage life of the product and which also meets the requirements posed on the appearance of the finished package to be marketed. The light shield can be formed with polymer layer toned grey with a black and a white pigment, e.g. as in WO 01/76976, the polymer layer forming an inner layer that replaces the conventional aluminium foil of the package, whereas on the opposite side of the package, i.e. on its outer surface, merely white pigment can be used, which affects the package appearance substantially by covering the discoloration of the fibre base caused by heating treatment.

An optional solution of the invention is to provide two successive pigmented polymer layers outside the fibre base in the package, with the outer polymer layer containing 5 to 25% of white pigment and the inner polymer layer closer to the fibre base containing black pigment in a small amount. These successive pigmented layers allow the light tone of the packaging material to be effectively stabilised despite yellowing of the subjacent fibre base. The overall colour of the material is then white or light grey, slightly toned grey under the effect of the black pigment underneath the white pigment. The brightness degree depends on the pigment amounts used and their mutual ratios, however, the idea is to adjust the material tone as close to white as possible and to maintain this tone during the heating treatment of the package.

A small amount of black pigment provided under a white-pigmented layer has a slightly light-absorbing effect. This effect may yet be inadequate in shielding the packaged product from light penetrating the material. If desired, more effective light-shielding pigmentation can be achieved by providing the polymer coating inside the package with a sufficient amount of light-absorbing pigment, e.g. by toning at least one inner coating layer of the fibre base grey, as disclosed in the WO patent specification 01/76976 mentioned above.
The desired material toning can be achieved with successive pigmented layers, whose total weight is 25 to 60 g/m², the black pigment concentration of the inner layer being in the range 0.05 to 0.5%, preferably approx. 0.06 to 0.15%, and the white pigment concentration in the outer layer being in the range 5 to 25%, preferably approx. 7 to 12%. Optionally, the inner layer containing black pigment can also be admixed with white pigment so as to get an overall light grey tone of the layer. The proportion of white pigment in the inner layer could thus be 5 to 25%, preferably 7 to 15%. Carbon black, for instance, is suitable as a black pigment, and titanium dioxide as a white pigment.

In a preferred embodiment of the invention, the package material comprises on both sides of the fibre base an outer transparent heat-sealing layer, with the pigmented polymer layers located inside these. This avoids the pigmented layer from getting into direct contact with the product to be packaged, which is prohibited by foodstuff legislation or regulations in a number of countries. However, the inner pigmented polymer layer may contain the same heat-sealable polymer as the outer layer and it may be located immediately underneath this, so that these layers during heat sealing act as a single uniform material layer forming the seam.

In an autoclave package, the fusion point of the polymer in the heat-sealing layer should be at least approx. 130 °C, thus avoiding fusion of the polymer in the autoclave. Polypropene is an example of such heat-sealable polymers.

Depending on the packaged product, the package material may further comprise one or more polymer oxygen-barrier layers, which most advantageously are located inside the package, between the fibre base and the pigmented light-shield layer. Especially ethylene vinyl alcohol copolymer (EVOH) and polyamide (PA) are suitable materials of the oxygen-barrier layer.

In the package of the invention, the fibre base of the material may consist particularly of a packaging board made of bleached pulp, having a weight in the range 130 to 500 g/m², or a packaging paper having a weight in the range 20 to 120 g/m². These are suitable for heat-sealable casing or carton packages or poach packages to be treated in an autoclave.

The heat-sealable packaging material of the invention, which is suitable for sterile packages as described above, comprising a fibre base and polymer heat-seal layers on its both sides, is characterised by the fact that pigment has been incorporated in the polymer layers on both sides of the fibre base, with the fibre base being hidden with white pigment on one side of the fibre base, and with a light-absorbing pigment forming a light shield for the packaged product on the opposite side of the fibre base. Such a material can be used for forming a light-shielding package for the product, which can be sterilised without any yellowing caused by heating substantially altering the aspect of the package.

The invention further comprises the use of the fibre-based, polymer-coated packaging material tinted by pigmenting on both sides in packages to be sterilised by heating. The invention relates in particular to the use of one of the packaging materials described in further detail above in food packages that have been sealed by heat sealing and are intended for treatment in an autoclave.

The invention is described in greater detail below by means of examples and with reference to the accompanying drawings, in which Figures 1 to 10 are schematic views of ten different layered packaging materials of the invention, and Figure 11 shows a package made from the packaging material of figure 1 by bending and heat sealing.

The polymer-coated packaging board of figure 1 comprises in the following order: an outer heat-sealing layer 1 made of polypropene (PP), an inner polypropene heat-sealing layer 2 pigmented white with titanium dioxide, a fibre base 4 made of bleached pulp, a polyamide (PA) oxygen-barrier layer 5 adhered directly to the fibre base, an EVOH oxygen-barrier layer 6, a polymer binder layer 7, a heat-sealable polypropene layer 8, which has been toned grey by means of carbon black and titanium dioxide, and a heat-sealing layer 9 made of polypropene. The successive coating layers can be produced on different sides of the board 4 by means of coextrusion. The material can be bent and heat-sealed to form a closed product package preferably with the polypropene layer 2 tinted white with titanium dioxide placed on the outer surface of the package, i.e. outside the fibre base 4, and with the polypropene layer 8 tinted grey by means of carbon black and titanium dioxide placed on the inner surface of the package, i.e. inside the fibre base 4. Owing to the layer 2 containing white pigment, the material generally preserves its brightness in a heat-sterilising treatment of the package made from it, such as autoclave treatment, despite any yellowing of the fibrous substrate 4. The grey layer 8 has the function of shielding the packaged product from light.

The packaging material shown in figure 2 differs from the one of figure 1 only in that the polypropene heat-sealing layer placed on the outer surface of the package has been omitted and in that the mutual order of PA and EVOH oxygen-barrier layers 5, 6 in the material has been changed. Thus the polypropene layer 2 tinted white with titanium dioxide is on the outer surface of the material, where it serves alone as a heat-sealable layer.

The packaging material of figure 3, again, differs from the one shown in figure 1 only in that the material of the pigmented polymer layers 2, 8 on both sides of the fibre base 4 is cyclo-olefin copolymer (COC) instead of polypropene. COC is a polymer obtained by copolymerisation of ethene and norbornene, which is poorly vapour-permeable and whose application in layered packaging materials is known per se.

The package material of figure 4 consists of a polypropene layer 1, a polypropene layer 2 pigmented white with titanium dioxide, a fibre base 4, a polypropene layer 9', a binder layer 7', a PA oxygen barrier layer 5, an EVOH...
The packaging material of figure 5 differs from the one shown in figure 4 in that the grey pigment composition is admixed in the two binder layers 8, 8' of the structure, so that the number of coating layers is reduced by one. The material comprises a coextruded seven-layer structure 9, 8', 5, 6', 5', 8, 9, which is symmetrical relative to the central EVOH layer 6. Figure 6 further shows a variant of the material of figure 5, in which only the innermost binder layer 8 contains grey pigment. This has the advantage of the separately manufactured five-layer film laminate 5, 6, 5', 7, 9 mentioned above, which can be sealed to the final layered packaging material as an integral assembly.

In the packaging materials of figures 1 to 6, the fibre base 4 may consist of a packaging board containing bleached sulphate pulp, having a weight in the range 130 to 500 g/m², preferably 170 to 300 g/m². If the fibre base optionally consists of bleached paper, it may have a weight in the range 20 to 120 g/m². The weight of the PA and EVOH oxygen-barrier layers 5, 6 may be 3 to 15 g/m², preferably 5 to 10 g/m². The weight of the transparent polypropene layers 1, 9 placed outermost in the material can be 5 to 30 g/m², preferably 7 to 20 g/m², and the inner pigmented polypropene layers 2, 8 adjacent these outer polypropene layers may have a weight in the range 10 to 50 g/m², preferably 25 to 40 g/m². The titanium dioxide concentration of the white-pigmented polypropene layer 2 may be 5 to 25%, preferably approx. 7 to 12%. The carbon black concentration in the grey-pigmented polypropene layer 8 may be 0.05 to 0.5%, preferably approx. 0.12 to 0.15% and the titanium dioxide concentration accordingly 5 to 25%, preferably approx. 7 to 12%. The binder layers 7, whose material is appropriately i.a. the polymer marketed by the company Mitsui Chemicals under the trade name Admer, may have a weight in the range 3 to 15 g/m², preferably 5 to 10 g/m². If the polymer material of the pigmented layers 2, 8 is COC or Admer instead of polypropene, the layer weights and pigment concentrations of the pigmented layers mentioned above apply to these as well.

The polymer-coated packaging board of figure 7 comprises in the following order: a coating layer 2 pigmented with titanium dioxide, a coating layer 3 pigmented with carbon black, a fibre base 4 made of bleached board, a light-shield layer 8 toned grey with titanium dioxide and carbon black so as to resemble an aluminium foil, and a transparent heat-sealing layer 9. The polymer material of all of the coating layers 2, 3, 8, 9 is polypropene. The successive coating layers can be formed on different sides of the fibre base 4 by co-extrusion. The material can be bent and heat-sealed to form a closed product package so that the successive, pigmented polypropene layers 2, 3 are placed on the outer surface of the package, i.e. outside the fibre base 4, and the grey light-shield layer 8 and the transparent heat-sealing layer 9 are placed on the inner surface of the package, i.e. inside the fibre base 4. The outer successive pigmented layers 2, 3 of the package impart the package a light, almost white shade, which does not change in a heat-sterilising treatment of the package.

Figure 8 shows a packaging board suitable especially for food packages treated in autoclaves, in which, compared with figure 7, there are the following added layers: a transparent polypropene heat-sealing layer 1 placed on the outer surface of the package, polyamide and EVOH oxygen-barrier layers 5, 6 inside the fibre base 4, and a binder layer 7 adhering to the light-shield layer 8 of the EVOH layer 6, whose material is e.g. the polymer marketed the company Mitsui Chemicals under the trade name Admer. Consequently, the package formed of the material is protected with pigmented layers 2, 3 against any yellowing of the fibre base 4 occurring in autoclave treatment, and the oxygen-barrier layers 5, 6 and the light-shield layer 8 inside the package protect the packaged product and extend its storage life and best before date.

Figure 9 shows a modification of the packaging board of figure 8, to which a second polyamide layer 5' and polypropene and binder layers 9, 7' have been added between the fibre base 4 and the polyamide layer 5. The arrangement enhances the adhesion between the oxygen-barrier layers and the fibre base. Additional features consist of the symmetrical five-layer combination of the binder 7', polyamide 5, EVOH 6, polyamide 5' and binder 7, which is an advantage when coating layers are formed by co-extrusion, and the provision for incorporating the five-layer structure of polypropene 9', binder 7', polyamide 5, EVOH 6 and polyamide 5' as a film laminate in the material, such film laminates being commercially available in the market. Such a finished laminate can be sealed to the board at the same time as the other coating layers of the material are produced by co-extrusion.

Figure 10 shows a second modification of the packaging material, which differs from the one shown in figure 9 only in that a second grey-pigmented light-shield layer 8' has been added inside the fibre base 4, so that the layer combination inside the fibre base has been made symmetrical in its totality, which is and advantage in terms of co-
extrusion.

In the packaging materials of figures 7 to 10, the white-pigmented layer 2 outside the fibre base 4 may have a weight in the range 20 to 50 g/m², and the layer 3 containing black pigment may have a weight in the range 5 to 10 g/m². The grey-pigmented light-shield layer 8 inside the fibre base 4 may have a weight in the range 10 to 50 g/m², preferably 25 to 40 g/m². The titanium dioxide concentration in the white-pigmented coating layer 2 may be in the range 5 to 25%, preferably 7 to 12%. The carbon black concentration in the inner coating layer 3 may be 0.05 to 0.5%, preferably 0.06 to 0.15%. If the layer 3 contains also titanium dioxide, it may have a concentration in the range 5 to 25%, preferably 7 to 15%. In other respects, the material layer weights are equal to those defined in conjunction with figures 1 to 6.

The packaging boards intended for use in autoclaves illustrated in figures 1 to 10 can be varied in different ways within the scope of the invention. Adequate oxygen barrier can be provided by means of one single EVOH layer 6, for instance, and then the polyamide layers can be omitted. If the pigmented layers on the outer surface of the package are used as heat-sealing layers, the outermost transparent heat-sealing layer 1 may also be superfluous. The innermost layer 3 containing black pigment, which is possibly provided, may be optionally admixed with white pigment, e.g. titanium dioxide, and then the layer gets a light grey overall shade.

Figure 11 shows a closed package product 10 shaped as a rectangular prism, which has been manufactured by bending and heat sealing blanks of the packaging material of figure 1. The figure includes a partial enlargement of the package wall, showing that the polymer layer 2 tinted white by pigmenting is placed outside the substrate board 4 in the package, and that the grey-pigmented polymer-layer 8 is placed inside this. Thus the outer surface of the package is white and its inner surface is grey, resembling an aluminium foil. At the seam points 11 of the package, the blank edges are overlapping and the polypropene layers 1, 2, 8, 9 of the opposite board sides are tightly heat sealed together.

In addition to the outermost transparent layers 1, 9, the pigmented polypropene layers 2, 8 also contribute to the heat sealing. The package is intended for sterilisation at the autoclave temperature of approx. 130 °C, at which the white layer 2 prevents the package from yellowing.

The material of package 10 of figure 11 can be varied, for instance by using any of the packaging materials illustrated in figures 2 to 10. In accordance with the invention, it is further possible to exclude the light-shield layer 8 inside the package from the materials of figures 7 to 10, provided that the outer layer 3 containing black pigment gives adequate light shield for the product. It is further possible, within the scope of the invention, to provide sterilised heat-sealed poach packages having a fibre base of paper and a weight in the range 20 to 120 g/m².

The following examples comprise experiments, which have primarily tested the effect achieved with pigments added to the polymer coating in covering yellowing of the fibre base of the packaging material during autoclave treatment. The examples have also measured the protection against humidification of the fibre base provided by polymer coatings. The autoclave treatment does not affect the light shield achieved with pigments on the opposite side of the fibre base, and this is why this effect has not been tested.

Example 1

Pieces of fibre-based packaging material were tested in an autoclave, in which the saturated vapour had a temperature of 130 °C. The fibre base of the material consisted of a packaging board made of bleached pulp having a weight of 250 g/m². The test material 1 consisted of this material as such. Test material 2 consisted of said board, with an aluminium foil laminated on its other side by means of a low-density polyethylene (LDPE) layer having a weight of 20 g/m², which acted as a binder. Test materials 3 to 11 were layered packaging materials, whose substrate consisted of said test material 2 and in which the board was equipped, on the side opposite to the aluminium foil, with one single polymer coating layer. The polymer of this layer was polyethylene (test material 3), polypropene (test materials 4 and 5), a mixture of 70% polypropene and 30% polyethylene (test materials 6 and 7), a pigmented mixture of 92% of the mixture of polypropene and polyethylene above and 8% titanium dioxide (test materials 8 and 9), and also cyclo-olefin copolymer (COC), which was the product Topas 8007D, producer Ticona GmbH.

The test material pieces were heated in an autoclave for 20 minutes at room temperature to the treatment temperature of 130 °C, at which the pieces were maintained for 0, 20, 40 or 60 minutes. After the treatment, the autoclave was cooled within 20 minutes, resuming room temperature, at which the test pieces were removed from the autoclave. For each test material, the brightness (ISO%) of the polymer-coated side of the material, i.e. opposite to the aluminium foil, was measured before the autoclave treatment (initial brightness) and after autoclave treatments of different durations. Accordingly, the moisture content of the materials was measured before the autoclave treatment (initial moisture) and after autoclave treatments of different durations. The results are presented in the following table 1, which also indicates the weight of the polymer-coating layer in each of the test materials 3 to 11.

</table>
The results show that regarding polymer-coated test materials 4 to 11, the fibre base had 14% maximum moisture content after autoclave treatment, which is still an acceptable value in view of the autoclave treatment of a package made of this material. In test material 3, the LDPE coating layer melted at autoclave temperature, and this is why the moisture content of the fibre base was not measured. Measurements of test material 2, i.e. uncoated aluminium/LDPE/board laminate, indicate strong water soaking of the unprotected fibre base in the autoclave.

A study of the measured brightness values before the autoclave treatment and after various treatment durations shows a progressive decrease in brightness as the treatment period increases, which is due to yellowing of the fibre base, which is not at all covered by the colourless polymer surface. With test materials 8 and 9, in which the polymer coating layer was pigmented, the brightness reduction was, however, substantially less than with materials equipped with an unpigmented colourless polymer coating. Consequently, white titanium dioxide pigment allows the yellowing of a fibre base occurring in autoclave treatment to be covered to a considerable extent.

Example 2

A series of tests in conformity with example 1 was made with materials, in which the fibre base consisted of packaging board made of bleached pulp, having a weight of 210 g/m² (test material 1). On one side of this board, an aluminium foil (test material 2) had been laminated by means of an LDPE binder layer having a weight of 20 g/m², and the opposite side of the board was additionally equipped with a two-layered polymer coating, whose inner layer contained a mixture of 70% of polypropene and 30% of polyethene, to which had been added titanium dioxide in various amounts, and whose outer layer was pure polypropene (test materials 3 to 12). The measured moisture contents of the fibre base and the brightness on the polymer coating side in the material before and after the autoclave treatment are shown in table 2. The table also contains the layer weights of the inner pigmented and the outer unpigmented polymer layers, respectively.

The results indicate a decrease in the brightness of the material as the autoclave treatment period increases, however, a comparison of the results with the brightness of the materials equipped with an unpigmented polymer coating of table 1 shows the considerable effect of the titanium dioxide pigment in covering the yellowing of the fibre base, the effect increasing with an increase of the pigment concentration and the weight of the pigmented layer, i.e. the layer thickness. A still better covering effect can obviously be achieved by further increasing the layer thickness of the pigmented polymer layer.

Example 3

In this example, the test series was performed with test materials free from aluminium, whose fibre base consisted of a packaging board made of bleached pulp, having a weight of 210 g/m² (test material 1). On one side, the board was coated with a polymer layer, in which polypropene was admixed with 7.5% of titanium dioxide and having a layer weight of 58 g/m² (test material 2). The opposite side of the board was coated with an unpigmented polymer coating layer (test material 3 to 6), or with a layered structure formed of two or three successive unpigmented polymer layers (test materials 7 to 11). The materials of the coating layers was polypropene (test materials 3 and 4), a mixture of 70% of polypropene and 30% of polyethylene (test materials 5 and 6), a two-layered structure, whose inner layer was COC (Topas 8007D) and outer layer said mixture of polypropene and polyethylene (test material 7), a three-layered structure, whose innermost layer was polyamide, following layer a binder (Admer NF 912E) and outermost layer said mixture of polypropene and polyethylene (test materials 8 and 9), or a three-layered structure, whose innermost layer was ethyl vinyl alcohol copolymer, intermediate layer a binder (Admer NF 912E) and outermost layer polypropene. The weights of the polymer layer(s) on the unpigmented side of the fibre base are indicated in the following table 3.

</table>
The autoclave treatments of the test materials were performed in the same manner as in examples 1 and 2, except that the duration of the autoclave treatment at a temperature of 130 °C was 0, 30 or 60 minutes, respectively, and the initial brightness of the material and brightness after a 60 minute autoclave treatment were measured on both sides of the material.

The results of table 3 show the crucial difference in the change of the brightness between the fibre base sides coated with pigmented and unpigmented coating. On the pigmented side, there was a slight decrease in the brightness of the material, and in all the cases, the brightness value after one hour of autoclave treatment was above 80% ISO. On the unpigmented side of the material, the brightness decreased notably as a result of yellowing of the fibre base, which the colourless coating layers are unable to cover.

Example 4 (comparative)

A test series was performed with a packaging material, whose fibre base consisted of a packaging board made of bleached pulp having a weight of 210 m/m². The board was coated on one side with a polymer layer covering against yellowing, in which polypropene was admixed with 7.5% of titanium dioxide and whose layer weight was 58 g/m². The opposite board side was coated with an unpigmented polymer coating layer (test materials 1 to 4) or a layer structure formed of two or three successive unpigmented polymer layers (test materials 5 to 9). The coating layer materials were polypropene (test materials 1 and 2), a mixture of 70% of polypropene and 30% of polyethene (test materials 3 and 4), a two-layered structure, whose inner layer was COC (Topas 8007D) and outer layer said mixture of polypropene and polyethene (test material 5), a three-layered structure, whose innermost layer was polyamide, following layer a binder (Admer NF 912E) and outermost layer said mixture of polypropene and polyethene (test materials 6 and 7), or a three-layered structure, whose innermost layer was ethyl vinyl alcohol polymer, intermediate layer a binder (Admer NF 912E) and outermost layer polypropene (test materials 8 and 9).

The test material pieces were heated in an autoclave for 20 minutes at room temperature to a treatment temperature of 130 °C, at which the pieces were kept for 60 minutes. After the treatment, the autoclave was cooled in 20 minutes, resuming room temperature, at which the test pieces were removed from the autoclave. The brightness (ISO %) on each side of each test material was measured before the autoclave treatment (initial brightness) and after the autoclave treatment. The results are shown in table 4, which also indicates the weights of the unpigmented polymer coating layers in each test material 1 to 9.

</table>
The test results of the table show the problem to be solved with the invention, i.e. the notable decrease of brightness due to yellowing of the fibre base, which the colourless coating layers on the unpigmented side of the fibre base have been unable to cover. Owing to the pigment, the initial brightness on the opposite side of the fibre base, pigmented with titanium dioxide as in FI patent application 20030260, was high and a slight decrease of brightness has occurred in the autoclave treatment, however, with a final brightness above 80% ISO in each case.

Example 5

A test series in conformity with example 4 was carried out with materials of the invention, in which the fibre base consisted of a packaging board made of bleached pulp, having a weight of 250 g/m². One side (the outer side) of this board, which is intended to be the outer surface of the autoclave package, was equipped with a two-layered polypropene coating, in the innermost layer of which polypropene was admixed with carbon black and titanium dioxide (test materials 1 to 7) or merely with carbon black (test materials 8 to 22), and whose outermost layer comprised polypropene admixed with titanium dioxide alone. In part of the materials (test materials 20 to 22), the opposite board side, which will be the inner surface in the autoclave package, was equipped with an inner light-shield layer based on polypropene and pigmented grey with carbon black (0.15%) and titanium dioxide (12.5%), having a weight of 27 g/m², and with a transparent polypropene layer covering this, having a weight of 23 g/m². The measured brightness of said outer material side before and after the autoclave treatment is shown in the following table 5. The table also comprises the pigment concentrations of the pigmented polymer layers on the outside of the material and the layer weights.

</table>
The results show that the packaging material of the invention can be toned to an optimum brightness of above 80% ISO, which undergoes a slight, practically negligible change during autoclave treatment. The final brightness after the treatment is almost the same as in FI patent application 20030260, however, with a clearly improved colour stability of the light shade during the treatment.

Claims

1. A heat-sealed heat-sterilised product package made of a polymer-coated fibre-based packaging material, characterised in that a first polymer coating layer outside the fibre base in the package contains white pigment, and in that a second polymer coating layer inside the first layer contains a light-absorbing pigment.

2. A package as defined in claim 1, characterised in that the coating layer containing a light-absorbing pigment is located inside the fibre base in the package.

3. A package as defined in claim 2, characterised in that the polymer coating outside the fibre base contains only white pigment, which hides the fibre base from sight.

4. A package as defined in claim 2, characterised in that outside the fibre base in the package there are two successive pigmented polymer layers, with the outer polymer layer containing 5 to 25% of white pigment and the inner polymer layer located closer to the fibre base containing black pigment, and that inside the fibre base there is a polymer layer containing light-absorbing pigment to provide a light shield for the packaged product.

5. A package as defined in any of claims 2 to 4, characterised in that inside the fibre base the polymer layer has been toned grey by mixing black and white pigments.

6. A package as defined in any of claims 2 to 5, characterised in that, both outside and inside the fibre base, the pigments are located in the innermost polymer layers covered by a transparent heat-sealable overlay layer.

7. A package as defined in claim 1, characterised in that outside the fibre base of the package there are two successive pigmented polymer layers, with the outer polymer layer containing 5 to 25% of white pigment and the inner polymer layer located closer to the fibre base containing a light-absorbing black pigment.

8. A package as defined in any of the preceding claims, characterised in that inside the fibre base of the package there is at least one polymer oxygen-barrier layer.

9. A package as defined in any of the preceding claims, characterised in that the outside of the heat-sterilised package has a brightness above 80% ISO.

10. A package as defined in any of the preceding claims, characterised in being a food package sterilised in an autoclave.

11. A polymer-coated heat-sealable packaging material intended for the product package of claim 1, comprising a fibre base and polymer heat-sealable layers on both sides of the substrate, characterised in that pigment has been incorporated in the polymer layers on both sides of the fibre base, with white pigment on one side of the fibre base hiding the fibre base and with a light-absorbing pigment on the opposite side of the fibre base forming a light shield.
for the product to be packaged.

12. A packaging material as defined in claim 11, characterised in that the brightness of the material is above 80% ISO on one side of the fibre base, where the polymer layer contains white pigment.

13. A packaging material as defined in claim 11 or 12, characterised in that the other side of the fibre base is provided with two successive pigmented polymer layers, with the outer polymer layer containing 5 to 25% of white pigment and the inner polymer layer located closer to the fibre base containing black pigment for stabilising the brightness of said material side despite any change during heating, and in that a pigmented light-shield polymer layer is provided on the opposite side of the fibre base.

14. A packaging material as defined in claim 13, characterised in that black and white pigments have been mixed in said inner polymer layer and in that the outer polymer layer contains exclusively white pigment.

15. A packaging material as defined in any of claims 11 to 14, characterised in that the light shield on the opposite side of the fibre base has been achieved by tinting the polymer layer grey with black and white pigments.

16. A packaging material as defined in any of claims 11 to 15, characterised in that the material comprises an outer transparent heat-seal layer on both sides of the fibre base and at least one inner pigmented polymer layer.

17. A packaging material as defined in claim 16, characterised in that the inner pigmented layer contains the same heat-sealable polymer as the outer layer.

18. A packaging material as defined in any of claims 11 to 17, characterised in that the polymer in the heat-seal layers has a fusion point of at least 130 °C.

19. A packaging material as defined in claim 18, characterised in that the heat-seal polymer is polypropene.

20. A packaging material as defined in any of claims 11 to 19, characterised in that the material comprises at least one polymer oxygen-barrier layer.

21. A packaging material as defined in claim 20, characterised in that the oxygen-barrier layer is located between the fibre base and the light-shield layer.

22. A packaging material as defined in claim 21, characterised in that the material of the oxygen-barrier layer or layers is ethylene vinyl alcohol polymer (EVOH) or polyamide (PA).

23. A packaging material as defined in any of claims 11 to 22, characterised in that the fibre base consists of bleached packaging paper or board.

24. Use of the packaging material of any of claims 11 to 23 for packages to be sterilised in an autoclave.

25. Use as defined in claim 24 for food packages to be sterilised in an autoclave.

Patentansprüche

2. Verpackung wie in Anspruch 1 definiert, dadurch gekennzeichnet, daß die ein Licht absorbierendes Pigment enthaltende Beschichtungsschicht in der Faserbasis in der Verpackung angeordnet ist.

3. Verpackung wie in Anspruch 2 definiert, dadurch gekennzeichnet, daß die Polymerbeschichtung außerhalb der Faserbasis nur ein weißes Pigment enthält, das die Faserbasis verdeckt.
4. Verpackung wie in Anspruch 2 definiert, dadurch gekennzeichnet, daß außerhalb der Faserbasis in der Verpackung zwei aufeinanderfolgende pigmentierte Polymerschichten angeordnet sind, wobei die äußere Polymerschicht 5 bis 25 % eines weißen Pigments und die innere Polymerschicht, die näher der Faserbasis angeordnet ist, ein schwarzes Pigment enthält, und daß in der Faserbasis eine Polymerschicht angeordnet ist, die ein lichtabsorbierendes Pigment enthält, um einen Lichtschutz für das verpackte Produkt bereitzustellen.

5. Verpackung wie in einem der Ansprüche 2 bis 4 definiert, dadurch gekennzeichnet, daß die Polymerschicht in der Faserbasis durch Mischen schwarzer und weißer Pigmente grau getönt ist.

6. Verpackung wie in einem der Ansprüche 2 bis 5 definiert, dadurch gekennzeichnet, daß außerhalb und innerhalb der Faserbasis die Pigmente in den zuinnerst liegenden Polymerschichten angeordnet sind, die mit einer transparenten wärmeversiegelbaren Deckschicht bedeckt sind.

7. Verpackung wie in Anspruch 1 definiert, dadurch gekennzeichnet, daß außerhalb der Faserbasis zwei aufeinanderfolgende pigmentierte Polymerschichten angeordnet sind, wobei die äußere Polymerschicht 5 bis 25 % weißes Pigment enthält und die innere Polymerschicht, die näher der Faserbasis angeordnet ist, ein lichtabsorbierendes schwarzes Pigment enthält.

8. Verpackung wie in einem der vorstehenden Ansprüche definiert, dadurch gekennzeichnet, daß die Polymerschicht in der Faserbasis der Verpackung wenigstens eine polymere Sauerstoffsperrschicht angeordnet ist.

9. Verpackung wie in einem der vorstehenden Ansprüche definiert, dadurch gekennzeichnet, daß das Äußere der heißsterilisierten Verpackung eine Helligkeit über 80 % ISO aufweist.

10. Verpackung wie in einem der vorstehenden Ansprüche definiert, dadurch gekennzeichnet, daß sie eine in einem Autoklaven sterilisierte Nahrungsmittelverpackung ist.

11. Polymerbeschichtetetes, wärmeversiegelbares Verpackungsmaterial für die Produktverpackung gemäß Anspruch 1, umfassend eine Faserbasis und polymere wärmeversiegelbare Schichten auf beiden Seiten des Substrats, dadurch gekennzeichnet, daß ein Pigment in die Polymerschichten auf beiden Seiten der Faserbasis eingegliedert ist, wobei ein weißes Pigment auf einer Seite der Faserbasis die Faserbasis verdeckt und ein lichtabsorbierendes Pigment auf der gegenüberliegenden Seite der Faserbasis einen Lichtschutz für das zu verpackende Produkt bildet.

13. Verpackungsmaterial wie in Anspruch 11 oder 12 definiert, dadurch gekennzeichnet, daß die andere Seite der Faserbasis mit zwei aufeinanderfolgenden pigmentierten Polymerschichten versehen ist, wobei die äußere Polymerschicht 5 bis 25 % weißes Pigment enthält und die innere Polymerschicht, die näher der Faserbasis angeordnet ist, ein schwarzes Pigment zum Stabilisieren der Helligkeit der Materialseite trotz Veränderungen während des Erwärmens enthält, und dadurch, daß eine pigmentierte Lichtschutzpolymerschicht auf der gegenüberliegenden Seite der Faserbasis angeordnet ist.

15. Verpackungsmaterial wie in einem der Ansprüche 11 bis 14 definiert, dadurch gekennzeichnet, daß der Lichtschutz auf der gegenüberliegenden Seite der Faserbasis durch Grautönen der Polymerschicht mit schwarzen und weißen Pigmenten erzielt wird.

16. Verpackungsmaterial wie in einem der Ansprüche 11 bis 15 definiert, dadurch gekennzeichnet, daß das Material eine äußere transparente Wärmesiegelschicht auf beiden Seiten der Faserbasis und wenigstens eine innere pigmentierte Polymerschicht umfaßt.

17. Verpackungsmaterial wie in Anspruch 16 definiert, dadurch gekennzeichnet, daß die innere pigmentierte Schicht das gleiche wärmeversiegelbare Polymer wie die äußere Schicht enthält.
Verpackungsmaterial wie in einem der Ansprüche 11 bis 17 definiert, dadurch gekennzeichnet, daß das Polymer in den Warmsiegelschichten einen Schmelzpunkt von wenigstens 130°C aufweist.

Verpackungsmaterial wie in Anspruch 18 definiert, dadurch gekennzeichnet, daß das Warmsiegelpolymer Polypropylen ist.

Verpackungsmaterial wie in einem der Ansprüche 11 bis 19 definiert, dadurch gekennzeichnet, daß das Material wenigstens eine polymere Sauerstoffsperrschicht umfaßt.

Verpackungsmaterial wie in Anspruch 20 definiert, dadurch gekennzeichnet, daß die Sauerstoffsperrschicht zwischen der Faserbasis und der Lichtschutzschicht angeordnet ist.

Verpackungsmaterial wie in Anspruch 18 definiert, dadurch gekennzeichnet, daß das Warmsiegelpolymer Polypropylen ist.

Verpackungsmaterial wie in einem der Ansprüche 11 bis 22 definiert, dadurch gekennzeichnet, daß das Material der Sauerstoffsperrschicht oder -schichten Ethylenvinylalkoholpolymer (EVOH) oder Polyamid (PA) ist.

Verpackungsmaterial wie in Anspruch 21 definiert, dadurch gekennzeichnet, daß die Sauerstoffsperrschicht zwischen der Faserbasis und der Lichtschutzschicht angeordnet ist.

Verpackungsmaterial wie in Anspruch 22 definiert, dadurch gekennzeichnet, daß die Sauerstoffsperrschicht oder -schichten Ethylenvinylalkoholpolymer (EVOH) oder Polyamid (PA) ist.

Verpackungsmaterial wie in einem der Ansprüche 11 bis 23 definiert, dadurch gekennzeichnet, daß die Faserbasis aus gebleichtem Packpapier oder Karton besteht.

Verwendung des Verpackungsmaterials gemäß einem der Ansprüche 11 bis 23 für in einem Autoklaven zu sterilisierende Verpackungen.

Verwendung wie in Anspruch 24 definiert für in einem Autoklaven zu sterilisierende Nahrungsmittelverpackungen.

Revendications

1. Emballage pour produit thermoscellé et stérilisé par la chaleur formé par un matériau d’emballage à base de fibres à revêtement polymère, caractérisé en ce qu’une première couche de revêtement polymère à l’extérieur de la base de fibres dans l’emballage contient un pigment blanc, et en ce qu’une seconde couche de revêtement polymère à l’intérieur de la première couche contient un pigment absorbant la lumière.

2. Emballage tel que défini dans la revendication 1, caractérisé en ce que la couche de revêtement contenant un pigment absorbant la lumière se trouve à l’intérieur de la base de fibres dans l’emballage.

3. Emballage tel que défini dans la revendication 2, caractérisé en ce que le revêtement polymère à l’extérieur de la base de fibres ne contient que le pigment blanc, qui cache la base de fibres de la vue.

4. Emballage tel que défini dans la revendication 2, caractérisé en ce qu’à l’extérieur de la base de fibres dans l’emballage il y a deux couches polymères pigmentées successives, la couche polymère extérieure contenant de 5 à 25 % de pigment blanc et la couche polymère intérieure, située plus près de la base de fibres, contenant un pigment noir, et en ce qu’à l’intérieur de la base de fibres il y a une couche polymère contenant un pigment absorbant la lumière pour fournir une protection contre la lumière au produit emballé.

5. Emballage tel que défini dans l’une quelconque des revendications 2 à 4, caractérisé en ce que l’intérieur de la base de fibres de la couche polymère a été teinté en gris par mélange de pigments noirs et blancs.

6. Emballage tel que défini dans l’une quelconque des revendications 2 à 5, caractérisé en ce que, à la fois à l’extérieur et à l’intérieur de la base de fibres, les pigments sont situés dans les couches polymères les plus à l’intérieur couvertes par une couche de surface transparente pouvant être thermoscellée.

7. Emballage tel que défini dans la revendication 1, caractérisé en ce qu’à l’extérieur de la base de fibres de l’emballage il y a deux couches polymères pigmentées successives, la couche polymère extérieure contenant de 5 à 25 % de pigment blanc et la couche polymère intérieure, située plus près de la base de fibres, contenant un pigment noir absorbant la lumière.

8. Emballage tel que défini dans l’une quelconque des revendications précédentes, caractérisé en ce qu’à l’intérieur de la base de fibres de l’emballage, il y a au moins une couche polymère formant barrière contre l’oxygène.
9. Emballage tel que défini dans l’une quelconque des revendications précédentes, **caractérisé en ce que** l’extérieur de l’emballage stérilisé par la chaleur a une brillance supérieure à 80 % d’ISO.

10. Emballage tel que défini dans l’une quelconque des revendications précédentes, **caractérisé en ce qu’il s’agit d’un emballage alimentaire stérilisé dans un autoclave.**

11. Matériau d’emballage à revêtement polymère pouvant être thermoscellé destiné à l’emballage pour produit selon la revendication 1, qui comprend une base de fibres et des couches polymères pouvant être thermoscellées sur les deux côtés du substrat, **caractérisé en ce que** le pigment a été incorporé dans les couches polymères sur les deux côtés de la base de fibres, avec le pigment blanc sur un côté de la base de fibres cachant la base de fibres et avec un pigment absorbant la lumière sur le côté opposé de la base de fibres formant une protection contre la lumière pour le produit à emballer.

12. Matériau d’emballage tel que défini dans la revendication 11, **caractérisé en ce que** la brillance du matériau est supérieure à 80 % d’ISO sur un côté de la base de fibres, où la couche polymère contient un pigment blanc.

13. Matériau d’emballage tel que défini dans la revendication 11 ou 12, **caractérisé en ce que** l’autre côté de la base de fibres est doté de deux couches polymères pigmentées successives, avec la couche polymère extérieure contenant de 5 à 25 % de pigment blanc et la couche polymère intérieure située plus près de la base de fibres contenant un pigment noir pour stabiliser la brillance dudit côté du matériau en dépit d’un changement quelconque durant le chauffage, et **en ce que** une couche polymère pigmentée de protection contre la lumière est prévue sur le côté opposé de la base de fibres.

14. Matériau d’emballage tel que défini dans la revendication 13, **caractérisé en ce que** les pigments noirs et blancs ont été mélangés dans ladite couche polymère intérieure et **en ce que** la couche polymère extérieure contient exclusivement un pigment blanc.

15. Matériau d’emballage tel que défini dans l’une quelconque des revendications 11 à 14, **caractérisé en ce que** la protection contre la lumière sur le côté opposé de la base de fibres a été obtenue en teignant la couche polymère en gris avec des pigments noirs et blancs.

16. Matériau d’emballage tel que défini dans l’une quelconque des revendications 11 à 15, **caractérisé en ce que** le matériau comprend une couche transparente thermoscellée extérieure sur les deux côtés de la base de fibres et au moins une couche polymère pigmentée intérieure.

17. Matériau d’emballage tel que défini dans la revendication 16, **caractérisé en ce que** la couche pigmentée intérieure contient le même polymère pouvant être thermoscellé que la couche extérieure.

18. Matériau d’emballage tel que défini dans l’une quelconque des revendications 11 à 17, **caractérisé en ce que** le polymère dans les couches thermoscellées a un point de fusion d’au moins 130°C.

19. Matériau d’emballage tel que défini dans la revendication 18, **caractérisé en ce que** le polymère thermoscellé est le polypropène.

20. Matériau d’emballage tel que défini dans l’une quelconque des revendications 11 à 19, **caractérisé en ce que** le matériau comprend au moins une couche polymère formant barrière contre l’oxygène.

21. Matériau d’emballage tel que défini dans la revendication 20, **caractérisé en ce que** la couche formant barrière contre l’oxygène se trouve entre la base de fibres et la couche de protection contre la lumière.

22. Matériau d’emballage tel que défini dans la revendication 21, **caractérisé en ce que** le matériau de la couche ou des couches formant barrière contre l’oxygène est un polymère éthylène-alcool vinylique (EVOH) ou un polyamide (PA).

23. Matériau d’emballage tel que défini dans l’une quelconque des revendications 11 à 22, **caractérisé en ce que** la base de fibres est constituée par un papier ou carton d’emballage blanchi.

24. Utilisation du matériau d’emballage selon l’une quelconque des revendications 11 à 23, pour des emballages à
stériliser dans un autoclave.

25. Utilisation telle que définie dans la revendication 24, pour des emballages alimentaires à stériliser dans un autoclave.
