Description

Field of the Invention.

[0001] The present invention relates to the treatment of cystic fibrosis (CF) with the secretin release stimulator camostat.

Background to the Invention.

Cystic Fibrosis.

[0002] Cystic fibrosis (CF) is the most common, fatal, autosomal recessive inherited disease, with over 7000 people currently diagnosed in the UK alone and approximately 30,000 in the United States. The incidence of CF is strongly dependent on ethnic background. Caucasian individuals with Northern European ancestry are most at risk exhibiting a probability of approximately 1 in 2500, based on a heterozygous carrier rate of about 1 in 25.

[0003] CF arises as a result of genetic mutation(s) in the gene of the cystic fibrosis transmembrane regulator (CFTR) chloride channel throughout the body. Such mutations in the CFTR lead either to incorrect folding of the protein and/or the lack of migration of the transcribed protein from the Endoplasmic Reticulum to the epithelial plasma membrane and subsequent loss of chloride (Cl-) channel function. This causes a cellular and luminal imbalance in fluid and electrolyte transport and volume within the lower respiratory tract of the CF lung, which reduces the constitution of the mucus which in turn impairs mucociliary clearance and initiates the inevitable and persistent bacterial infections within the lung of CF patients. Different mutations give rise to CF symptoms of varying severity and correspondingly lead to variations in patient survival rates.

[0004] Over the last few decades, improved drug and physiotherapy treatments have improved patient survival time significantly, though average life expectancy is still short, currently around 30 years. There is therefore a continuing need to develop better treatment for this condition.

Secretin.

[0005] Secretin is a peptide hormone which is secreted from S cells in the proximal small intestine (especially the duodenum and jejunum) in response to acidic contents leaving the stomach. The structure of porcine secretin has been known for some time and it has been isolated from porcine intestine and has been found to be constituted by a peptide composed of 27 amino acid residues (Mutt et al, 1970). Moreover, it has been found that bovine and porcine secretins are identical, and are also similar to canine secretin.

[0006] Although bovine and porcine secretins behave identically with human secretin in some respects they are not structurally identical. These animal secretins differ from the human secretin at positions 15 and 16. An alignment of human, porcine and canine secretin is shown in Figure 1.

[0007] Secretin's physiological role is to stimulate water (H₂O) and bicarbonate (HCO₃⁻) secretion from the pancreas, leading to the neutralisation of acidic chyme. Its actions are mediated via a seven transmembrane domain, G protein coupled receptor (GPCR), a member of the glucagon-secretin-vasoactive intestinal peptide structurally related superfamily of GPCRs (IUPHAR Receptor Compendium, 1998), for which the peptide exhibits nanomolar affinity. Secretin receptor stimulation mediates increases in intracellular cAMP, and the activation of protein kinase A (PKA).

[0008] Secretin is currently approved by the FDA to diagnose gastrinoma and assess pancreatic function. Anecdotal reports from "off-label" use of secretin in paediatric autism suggest that it may improve both physiological and behavioural symptoms associated with autism, a disorder characterized by severely impaired communication, social skills and development (see for example WO98/52593, US-A-6,020,310 or US-A-6,020,314). In March 2000 Repligen Corporation (USA) announced it had initiated a Phase II clinical trial with secretin in children with autism, with the Phase II trial sites including the Mayo Clinic, the University of Rochester Medical Center and the Southwest Autism Research Center in collaboration with Phoenix Children's Hospital. Initial results of these trials suggest that secretin infusion may be beneficial in discrete groups of severely autistic children.

[0009] Secretin has also been proposed for the prophylaxis of the aspiration pneumonia syndrome (e.g. in EP0150760: AU3806485).

[0010] There are a wide number of reported synthetic and/or naturally occurring secretin peptide analogues and fragments (referred to herein as "secretin receptor ligands") which exhibit a wide range of potencies, efficacies and selectivity for the secretin receptor. These include, but are not limited to mono / poly substituted secretin analogues, secretin fragments, substituted secretin fragments, reduced peptide bond analogues (Gardner et al, 1976; Gardner et al, 1979; Waelbroeck et al, 1981; Konig et al, 1984; Staun-Olsen et al, 1986; Robbertecht et al, 1988; Haffer et al, 1991), and naturally occurring and synthetic analogues, fragment and chimeric peptides of the VIP/secretin family (including VIP (vasoactive intestinal peptide), gastric inhibitory peptide (GIP), PACAP (pituitary adenylate cyclase-activating poly-
petide), adrenomedullin, calcitonin, CGRP (alpha, beta and skin calcitonin gene related peptides), glucagon, glucagon-like peptide (GLP), growth hormone-releasing factor, parathyroid hormone (PTH) and its related protein (PTHrP), corticotrophin-releasing hormone (CRH) and amylin. Many of these peptides (including glucagon, GLP, PACAP and VIP) share significant amino acid homology, particularly in the amino terminus with secretin. All these peptides are thought to adopt similar secondary structural characteristics, including one or two regions of amphipathic α-helical secondary structure, and appear to interact with their receptors in a well conserved manner (Sexton, 1999).

[0011] Also known are secretin-related receptor peptides, and associated analogues and fragments which exhibit affinity for the secretin receptor.

Disclosure of the Invention.

[0012] We have studied the expression levels of secretin receptor in tissue from patients with CF and COPD. We have found that in both normal individuals and patients with these disease conditions, secretin receptor is expressed in the distal regions of the lung, particularly the tertiary bronchus and parenchyma, with little or no measurable mRNA expression in more proximal regions of the lung. The expression of secretin receptor in these tissues has not previously been reported.

[0013] We have moreover surprisingly found that levels of secretin receptor mRNA in tertiary bronchus of CF patients are significantly elevated. This elevation is specific to CF, and not shared by patients with other lung disorders. The elevation was specific to tissue of the tertiary bronchus.

[0014] While not wishing to be bound by any one particular theory, we believe the action of secretin on ion movements in cells (see below) will counteract the effect of the CTFR deficiency associated with CF. Further, although the operation of the present invention does not rely upon any one particular theory, an explanation of the elevated levels of secretin receptor mRNA in tertiary bronchial tissue is that this is in response to the ion imbalance experienced in these cells.

[0015] Moreover, in patients with COPD there is increasing recognition that the role of ion efflux in the lungs of patients may be a critical target for therapeutic intervention. The secretin receptor is coupled to the G-protein, Gs, and therefore it can be envisaged that activation of the functional secretin receptor that has been identified herein on epithelial cells lining the distal human bronchus will result in the accumulation of intracellular cAMP, and subsequent bronchodilation (see also Ng et al, 1999). Moreover in other mucus hypersecretory lung diseases, such as cystic fibrosis and COPD, reduction of predominantly Cl- efflux alters the aqueous and ionic composition and subsequent viscosity of mucus and mucus secretions, leading to thick insipid mucus which impairs mucociliary clearance from the lung. Thus the stimulation of ion movement in such patients may thus be beneficial in the treatment of their disease.

[0016] Accordingly, the present invention provides a medicament for treatment of cystic fibrosis in a patient suffering from CF, for use in a method comprising administering to said patient an effective amount of an agent which triggers anion efflux in respiratory tissue via the activation of a secretin receptor.

[0017] The present invention is in one part based on the surprising finding by the inventors of elevated levels of secretin receptor mRNA in the tertiary bronchus of CF patients, and relates to the novel use of secretin in the treatment of cystic fibrosis. It has been contemplated by the inventors that secretin may be delivered to the patient in an effective amount by means other than directly administering the secretin receptor ligand itself. An alternative method of administering secretin is by the use of agents which stimulate the up-regulation of the production and or release of endogenous secretin in pulmonary cells, or secretin related peptides.

[0018] The invention also provides the use of an agent which triggers anion efflux in respiratory tissue via the activation of a secretin receptor for the manufacture of a medicament for the treatment of cystic fibrosis.

Brief Description of the Drawings.

[0019]

Figure 1 shows an alignment of human, porcine and canine secretin.

Figure 2 shows differential expression of mRNA of the secretin receptor in control and CF lung regions.

Figure 3 shows mRNA expression of GAPDH in control and lung CF regions.

Figure 4 shows differential expression of mRNA of the secretin receptor in control and CF lung regions from a sample of 16 control and 25 CF tissue donors.

Figure 5 shows that secretin stimulates ionic movement in the non-CF tertiary bronchus.

Figure 6 shows that secretin stimulates non-CTFR dependent ionic movement in confluent monolayers of primary epithelial cells.
human tertiary bronchial epithelial cells derived from non-CF donors.

Figure 7 shows that secretin stimulates ionic movement in the human CF tertiary bronchus.

Figure 8 shows the effect of secretin on chloride ion efflux in primary human tertiary bronchial epithelial cells derived from non CF donors.

Figure 9 shows the levels of NeuroD mRNA in tertiary bronchus and lung parenchyma of CF patients.

Detailed Description of the Invention.

Agent which triggers anion efflux in respiratory tissue via the activation of a secretin receptor.

[0020] There are a number of mechanisms by which secretin receptors may be activated. For example, expression of secretin is widely reported to be restricted to S-type enteroendocrine cells in the small intestine and colonic enteroendocrine cells and insulin producing β cells of the developing pancreas. Both enteroendocrine cells and pancreatic islets arise from the primitive embryonic gut endoderm. In addition, the primary airways are formed through a process termed branching morphogenesis, whereby 2 ventral lung buds sprout from the epithelium lining the floor of the embryonic foregut endoderm. Patterning of the airways is then accomplished by the outgrowth and repetitive branching of the two long buds. Pulmonary neuroendocrine (PNE) cells are amongst the first cells to differentiate from the primitive lung epithelium, and are generally most abundant in the airways of fetal and neonatal lungs. These cells are known to express a number of peptides including calcitonin, calcitonin gene related peptide, serotonin and endothelin, and can be visualized by their immunoreactivity to these peptides or to general endocrine markers such synaptophysin, chromogranin and protein gene product 9.5. In the CF bronchus, increased calcitonin immunoreactivity within endocrine cells has been demonstrated (Wolf et al, 1986).

[0021] We have found that there is increased chromogranin A immunoreactivity in CF tertiary bronchial sections compared to non CF lung, suggestive of an increased number of solitary endocrine cells in CF lung. Increased expression of endocrine cells within the tertiary bronchus of the CF lung would be expected to correlate with the increased presence of endocrine peptides including secretin. As such, direct or indirect stimulation of endocrine cells to locally release secretin (and/or secretin releasing peptides or peptides which exhibit affinity for the secretin receptor) within the lung would represent an alternative approach to stimulating the secretin receptor with exogenous secretin, or a mimetic and providing a therapeutic benefit in CF.

[0022] Further, the secretin gene may be upregulated by the provision of agents which increase the level of transcription of the gene, e.g. via promoter or enhancer regulation. The enhancer region of the secretin gene contains a cis-acting DNA consensus sequence (CAGCTG) known as an E box, which bind proteins belonging to the basic helix-loop-helix (bHLH) family of transcription factors. A bHLH protein known as BETA2/NeuroD has been demonstrated to lead to the tissue-specific regulation of secretin gene transcription (Mutoh et al, 1997). In knock out mice, BETA2/NeuroD deficient mice fail to develop enteroendocrine cells or pancreatic β cells, demonstrating the critical role of this transcription factor in the normal development of several specialized cells types that arise from the gut endoderm. Beta2/NeuroD expression has been demonstrated to locate only to endocrine cells in transgenic mice (Rhindi et al, 1999).

[0023] In addition, up regulation of endogenous secretin production may also be achieved by a variety of other methods known in the art (e.g. see Jiang et al., 2001; Yang et al., 1998; Morse et al., 2001; Lewis et al., 1997; West & Rodman, 2001; Alton & Kitson, 2000) including but not limited to gene therapy (delivery of DNA or RNA in a viral or non viral vector encoding a peptide capable of directly or indirectly stimulating the secretin receptor or its cell signaling pathway), or gene targeting (delivery of agents which target regulatory sequences or transcription factor binding sites on the promoter region of the gene encoding secretin or a related peptide, thereby switching on production of secretin or a related peptide capable of directly or indirectly stimulating the secretin receptor).

[0024] A number of mechanisms are known to stimulate secretin release, including the following:

Agents such as dibutylryl cyclic-3',5'-adenosine monophosphate, forskolin, 4 beta-12-O-tetradecanoylphorbol-13-acetate, the synthetic serine protease inhibitor, camostat, and the calcium ionophore, A2318, which stimulate Ca\(^{2+}\) and cyclic-3',5'-adenosine monophosphate-dependent secretin release (Xue et al, 1993);

Pancreatic phospholipase A\(_2\) (PL\(_{A2}\)) which has been demonstrated to intrinsically possess secretin-releasing activity, which is independent of its digestive enzymatic activity (Chang et al, 1999);

The neuropeptides bombesin, gastrin releasing peptide, VIP and galanin have also been shown to modulate secretin release in secretin-producing cells (Chang et al, 1998); and

Long chain fatty acids, such as sodium oleate are potent stimulators of secretin release from endocrine cells. Their stimulatory effect is potentiated by endogenous protein kinase A and mediated by activation of Ca\(^{2+}\) influx through
Further, receptor activity modifying proteins, or RAMP are novel single transmembrane domain proteins that can modulate the expression and/or activity of at least two members of the secretin receptor GPCR family. To date there are 3 RAMP isoforms, 1-3, whose interactions are suggested to potentially result in trafficking of the receptor to the cell surface, modifying the degree of receptor glycosylation, and/or contributing to the ligand binding site through association with the receptor at the cell surface (Sexton, 1999).

RAMPS may indirectly alter a peptide selectivity for a specific receptor of the secretin GPCR family. For example, studies in which a single point mutation of the PTH1 receptor confers secretin responsiveness to this receptor, while the reverse mutation confers PTH responsiveness to the secretin receptor (Turner et al, 1996) has been suggested could be due to alterations in specific RAMP interactions with the receptor. (Sexton, 1999).

As such, agonism of the secretin receptor could be mediated via the simultaneous or sequential application of a peptide analogue or fragment of the secretin receptor family and a specific RAMP.

Respiratory tissue in which secretin receptors are activated particularly includes tissue within the distal regions of the lung selected from tertiary bronchus and lung parenchyma.

Compositions of the Invention.

The novel findings reported herein give rise to novel compositions which comprise camostat together with at least one other compound active against CF wherein this other compound action against CF is chosen from hederocromil or from mucolytic agents such as acetylcysteine, deoxyribonuclease I (dornase) or erdosteine.

With regard to construction of the delivery device, any form of aerosolization known in the art, including but not limited to nebulization, atomization or pump aerosolization of a liquid formulation, and aerosolization of a dry powder formulation, can be used in the practice of the invention. A delivery device that is uniquely designed for administration of solid formulations is envisioned. Often, the aerosolization of a liquid or a dry powder formulation will require a propellant. The propellant can be any propellant generally used in the art. Examples of useful propellants include chlorofluorocarbons, hydrofluorocarbons, hydrochlorofluorocarbons, and hydrocarbons, including trifluoromethane, dichlorodifluoromethane, dichlorotetrafluoroethanol, and 1,1,1,2-tetrafluoroethane, and combinations thereof.

In a preferred aspect of the invention, the device for aerosolization is a metered dose inhaler. A metered dose inhaler provides a specific dosage when administered, rather than a variable dose depending on administration. Such a metered dose inhaler can be used with either a liquid or a dry powder aerosol formulation.

Systems of aerosol delivery, such as the pressurized metered dose inhaler and the dry powder inhaler are disclosed in Newman, Aerosols and the Lung, Clarke, S.W. and Davia, D. editors, pp 197-22 and can be used in connection with the present invention.

Additional pharmaceutical methods may be employed to control the duration of action of the antagonists of this invention. The antagonists also may be entrapped in microcapsules prepared, for example, by coacervation techniques by interfacial polymerization (for example, hydroxyethylcellulose or gelatin-microcapsules and poly-(methylmethacrylate)microcapsules, respectively), in colloidal drug delivery systems (for example, liposomes, albumin microspheres, microemulsions, nano-particles and nanocapsules), or in macroemulsions. Such techniques are disclosed in Remington’s Pharmaceutical Sciences, 16th edition, Oisol, A., ed (1980).

Preparations for parenteral administration includes sterile aqueous or non-aqueous solutions, suspensions or emulsions. Examples of non-aqueous solvents or suspending media are propylene glycol, vegetable oils, such as olive oil, and injectible organic esters, such as ethyl oleate. These compositions may also contain adjuvants, such as preserving, wetting, emulsifying and dispersing agents. They may be sterilized, for example, by filtration through a bacteria-retaining filter, by incorporation of sterilizing agents in the composition, by irradiation or by heating. They may be also be manufactured in the form of sterile solid compositions, which can be dissolved in a sterile injectible medium immediately before use. As well as the more customary intravenous and intramuscular routes the compositions may also be administered by intraarticular injection.

The percentages of active ingredient in the compositions of the invention may be varied as long as they constitute a proportion such that a suitable dosage for the desired stimulatory effect on the pancreas is obtained. Obviously several unit dosage forms may be administered at about the same time. Generally, the compositions should contain from about 0.1% to about 80% by weight of active ingredient.

The dose employed depends upon the desired stimulatory effect, the route of administration and the duration of the treatment. Typical doses may be in the range of from 10^-6 to 10^-3 mg per day, preferably from 10^-6 to 10^-4 mg per day for a human patient. The secretin receptor ligand may be administered each day or, according to the wishes of the medical practitioner, less often, e.g. weekly, or until the desired therapeutic effect is achieved.

The following examples illustrate the invention.
Example 1: RNA Expression Profiles.

[0038] Messenger RNA expression profiles of the secretin receptor (protein accession P47872; nucleotide accession U28281) was examined. Total RNA was isolated from tertiary / quaternary bronchus and lung parenchyma from 5 control and 5 CF donors using TriZol™a commercially available solution of phenol and guanidine isothiocyanate, according to the protocol described by the manufacturer (Life Technologies). Samples of RNA were used only if intact 18s and 28s ribosomal RNA were detected by gel electrophoresis and if genomic DNA formed less than 10% of the total nucleic acid sample. Total RNA samples were annealed to the primer probe sequence plus a glyceraldehyde-3-phosphate dehydrogenase (GAPDH; accession no. P04406) primer and reverse transcribed using MuLV reverse transcriptase. Quantitative sequence detection was carried out on the resulting cDNA.

[0039] The applicants have developed protocols for quantitative analysis of mRNA expression using the ABI prism 7700 Sequence Detection System (Perkin Elmer). Details of the system are set out in WO00/05409. In brief, the system uses fluorogenic probes to generate sequence specific fluorescent signals during PCR. The probes are oligonucleotides with fluorescent reporter and quencher dyes attached. While a probe is intact, the intensity of reporter fluorescence is suppressed by a quencher. When a probe forms part of a replication complex during the PCR process, the quencher is separated from the reporter dye resulting in an increase in fluorescence which is then detected by the ABI 7700 sequence detector. The ABI 7700 has a built in thermal cycler, and a laser directed at each of the 96 sample wells via bi-directional fibre optic cables. Emitted fluorescence through the cables to a detector where emissions which fall between 520nm and 660nm are collected every few seconds. The system software analyses the contribution of each component dye to the experiment spectrum, and normalises the signal to an internal reference dye. The peaks of these normalised ‘reporter’ values (Rn) are then plotted against thermal cycle number to produce an amplification plot - to allow visualisation of the extent of PCR product generation.

[0040] The starting copy number of a target sequence (Cn) is established by determining the fractional PCR cycle number (Ct) at which a PCR product is first detected - the point at which the fluorescence signal exceeds a threshold baseline. Therefore the lower a Ct value the greater the Cn. Quantification of the amount of target mRNA in each sample is established through comparison of the experimental Ct values with standard curves for the target sequence which are constructed during each experiment.

[0041] Primer probe sets were specifically designed for the detection of secretin receptor mRNA. Off-line homology searches revealed no significant matches with gene sequences logged at Genbank. Forward and reverse primer and probe sequences for the secretin receptor were as follows :

<table>
<thead>
<tr>
<th>Primer</th>
<th>Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Forward</td>
<td>GACCAGCATCATCTGGAGGGCT (SEQ ID NO:1)</td>

</tbody>
</table>

[0043] Reaction conditions were optimised using genomic DNA as a template and a primer probe concentration grid followed by a probe concentration gradient experiment. Primer concentrations were selected to give the most efficient amplification of gene product, i.e. those which generate a low threshold cycle and a relatively high accumulation of fluorescence. These optimal primer concentrations were then used to select the optimum probe concentration.

[0044] A respiratory disease association of the secretin receptor was demonstrated by profiling secretin receptor mRNA expression in the tertiary bronchus and parenchyma from up to 5 fully consented donors pathologically and histologically diagnosed with the following respiratory disorders: non-smoker control, smoker, asthmatic, cystic fibrosis, pneumonia, emphysema, chronic obstructive pulmonary disease (COPD). CF lung tissue was obtained by full consent from 5 patients undergoing heart and lung transplants.

[0045] Figure 2 shows the differential mRNA expression of the secretin receptor in control and CF lung regions, illustrating increased expression of the secretin receptor in CF tertiary bronchus. Data are representative of the mean ± s.e.m QRT-PCR threshold cycle from 5 control and 5 cystic fibrosis tissue donors in each lung region. * p=0.0246 denotes statistical significance derived from an unpaired Students T-test. As a control, Figure 3 shows mRNA expression of GAPDH in control and CF lung regions. Data are representative of the mean ± s.e.m QRT-PCR threshold cycle from 5 control and 5 cystic fibrosis tissue donors in each lung region. No statistical differences were observed within or
between groups.

[0046] Decreased secretin receptor expression was demonstrated in the lung parenchyma of 5 COPD donors in comparison to 5 control donors (p=0.0465). However no other donor groups exhibited differences in the expression of secretin receptor mRNA.

[0047] In all cases, however, the observation of secretin receptor expression at any level in tissues of the distal regions of the lung is novel and provides the underlying basis for the present invention.

[0048] Figure 4 shows the results of a subsequent expression study carried out with tissue derived from 25 CF donors and 16 non-smoking control donors. Data are representative of the mean ± s.e.mean QRT-PCR threshold cycle from 25 CF donors and 16 non-smoking control donors in each lung region. ** p=0.009 denotes statistical significance derived from two-way analysis of variance. The results obtained were similar to those obtained in Figure 2, i.e. significantly increased expression of the secretin receptor in CF tertiary bronchus compared to control, with both groups having similar levels of expression in the parenchyma.

[0049] The data provided by Example 1 provides the underlying basis for the present invention. That is, impaired Cl− efflux from cells in the respiratory tract into the airway lumen represents the etiological problem in CF. However, this loss of the Cl− channel and ion movement also impairs bicarbonate (HCO3−) secretion from cells and enhances sodium ion (Na+) reabsorption into cells, via epithelial, amiloride-sensitive Na+ channels.

[0050] The lavage of the healthy lung consists primarily of H2O (approx. 95%), with luminal HCO3− maintaining secreted proteins such as mucus and digestive enzymes in a soluble, inactive state. However, CF airway epithelia exhibit abnormally high rates of surface liquid absorption due to the high intracellular concentrations of Na+ and Cl− and therefore patients have a very low moisture content within their airways. Together this leads to significant thickening of the mucus, and subsequent impairment of the mucociliary clearance from the CF lung.

[0051] Movement of HCO3− across apical membrane of lung epithelial cells occurs predominantly via an electrogenic Cl−/HCO3− exchanger, with water crossing hydrophobic plasma membranes either by simple osmotic diffusion or through a facilitative transport mechanism mediated by members of a family of aquaporin (AQP) water channel proteins. Currently it is thought that HCO3− and Cl− are predominantly involved in the osmotic movement of H2O.

[0052] Based on the physiological role of secretin and its receptor in ionic regulation in the duodenum and pancreas, the applicants suggest, based on the present findings, that increased mRNA and functional expression of the secretin receptor may represent the human body's evolutionary, pathophysical response in order to compensate for the defect in the CFTR. As secretin peptide synthesis occurs in the duodenum, secretin receptors within the lung will not be exposed to the secretin peptide. While not being bound by any one particular theory, it is proposed that agonism of the secretin receptor by pharmacological intervention will treat the underlying biochemical respiratory problems associated with CF by all or some of the following:

(a) Stimulating Cl− efflux via cAMP-dependent activation of Cl− channels from respiratory cells of the tertiary bronchus. Secretin receptor stimulation or forskolin-mediated increases in cAMP have been shown to stimulate a small, single channel Cl− selective conductance, of about 4pS across the apical membrane of rat pancreatic duct cells (Gray et al., 1988). Although secretin has been demonstrated to stimulate the CFTR and Cl− efflux across the apical membranes of non-CF human epithelial cells (e.g. gallbladder; Dray-Charier et al, 1995), this Cl− conductance is reported to be 6-12pS. Therefore this Cl− represents an alternative cAMP-dependent Cl− conductance.

(b) Stimulated increases in cAMP, activating protein kinases, and leading to the phosphorylation and subsequent regulation of epithelial Na+ channels or Na+−K+−ATPases in respiratory cells, thereby reducing Na+ reabsorption and stimulation of lung liquid movement. Such a mechanism has been demonstrated in the rat alveolar epithelial cells with cAMP coupled beta-adrenergic receptor stimulation (Minakata et al., 1998).

(c) Subsequently increased luminal levels of Cl− will act as a substrate for the secretin activated Cl−/HCO3− exchanger, allowing the electrogenic movement of HCO3− into the airway lumen. Secretin has been widely demonstrated to stimulate the activity of Cl−/HCO3− exchanger which is functionally coupled with a CAMP-dependent Cl− channel (CFTR) on the apical epithelium (for example in bile duct epithelial cells, Alvaro et al, 1993; 1997). This ionic movement mediated by secretin has been demonstrated to stimulate electrogenic Na+−HCO3− cotransport, leading to correction of intracellular pH (Ishiguro et al, 1993).

(d) Additionally, increased HCO3− levels are known to maintain secreted proteins in mucus in a soluble, inactive state (Lee et al., 1999).

(e) Induce the translocation and insertion of AQP[s into the plasma membrane, allowing the movement of water into the lumen of the airways. In rat cholangiocytes, secretin has been demonstrated to cause a 60 % concentration dependent increase in osmotic H2O permeability by inducing the translocation of AQP-1 water channels (Marinelli
et al, 1997). This process will also be assisted by the osmotic diffusion of H₂O across the plasma membrane, due to the correction of Na⁺, Cl⁻, HCO₃⁻ and pH via the previously described mechanisms, in bronchial cells and the airway lumen.

[0053] In support of these proposals, we investigated the action of secretin on tertiary bronchus tissue samples.

**Example 2: Functional activity of secretin receptor in tertiary bronchus.**

[0054] Functional activity of the secretin receptor was examined in the tertiary bronchus and in epithelial cells derived from the tertiary bronchus of normal tissue.

[0055] In brief, non-branched regions of the human tertiary bronchus from non-CF donors were dissected, cut longitudinally and mounted between the two compartments of a modified Ussing chamber to measure the short circuit current across the bronchial wall. Both luminal (airway) and basolateral membranes were bathed in oxygenated Krebs extracellular solution and the tissue voltage clamped to zero to allow changes in short circuit current in response to secretin to be measured. Amiloride at a concentration of 10 μM was initially added to the luminal membrane (Figure 5, point a) (as described by those in the art) to partially block the predominant sodium ion current and unmask underlying ionic currents. On attainment of a stable base line, 3μM human secretin (supplied by Sigma, catalogue number S714) was added to the luminal membrane (Figure 5, point b).

[0056] Secretin was found to stimulate ionic movement in a manner consistent with the movement of a negatively charged ion (Cl⁻ and/or HCO₃⁻) (Figure 5). Like secretin, addition of 10μM ATP or UTP to the apical membrane of the lung epithelium (Figure 5, point c) was demonstrated to stimulate a similar ionic movement of similar magnitude. These ATP and UTP mediated effects are widely reported in the literature to be due to the stimulation of a Ca²⁺-activated Cl⁻ current via the P2Y2 purinoceptor. Both described agonists, at high concentrations produced responses of a similar magnitude.

[0057] Functional effects of the secretin receptor were probed in epithelial cells derived from the human tertiary bronchus. In brief, tertiary bronchial epithelial were isolated by overnight protease digestion and then cultured until confluency on Snapwell (Costar) permeable supports. The supports were mounted in a modified Ussing chamber, and both luminal and basolateral membranes were bathed in oxygenated Krebs extracellular solution. The cells were voltage clamped to zero to allow changes in short circuit current in response to secretin to be measured. As previously described, 10 μM amiloride was initially added to the luminal membrane (Figure 6, point a) followed by the addition of 100 nM secretin to the luminal membrane (Figure 6, point b). Consistent with observations in the tertiary bronchus, secretin stimulated ionic movement in a manner consistent with the movement of a negatively charged ion (Cl⁻ and/or HCO₃⁻). Furthermore, addition of 500 μM glibenclamide, a recognised inhibitor of the CFTR failed to suppress secretin mediated ionic movement, suggestive that a similar ionic movement would be observed in CF tertiary bronchial epithelial cells.

**Example 3: Stimulation of ionic movement in CF bronchus.**

[0058] The experiment described above was repeated using human CF tertiary bronchus, using 1 μM secretin. The result obtained is shown in Figure 7. At point (a), addition of amiloride blocks the underlying sodium current. Addition of 1 μM secretin at point (b) stimulates ionic movement of a negatively charged ion, confirming the experimental observations in the non-CF bronchus.

**Example 4: Stimulation of chloride ion efflux by secretin in tertiary bronchus.**

[0059] Ionic movement in tertiary bronchial epithelial cells was further characterised with the use of the Cl⁻ specific fluorescent probe MQAE (n-(ethoxycarbonylmethyl)-6-methoxyquinolinium bromide; Molecular Probes). In brief, primary human, tertiary bronchial epithelial cells were isolated as previously described and cultured in a 96 well plate. On reaching confluency, cells were loaded overnight with 4 mM MQAE. Cells were washed in a chloride containing HEPES buffer, before passive Cl⁻ efflux was initiated by the addition of a Cl⁻ free buffer. Addition of nanomolar concentrations of secretin stimulated Cl⁻ efflux, as determined by changes in MQAE fluorescence. Secretin mediated changes in fluorescence were abolished by the addition of the non-selective Cl⁻ blocker NPPB (5-nitro-2-(3-phenylpropylamino)benzoic acid; 100μM). The results are shown in Figure 8 which shows the effect of secretin at two concentrations (open diamonds 12.5 nM; closed circles 100 nM). 100nM Secretin mediated Cl⁻ efflux was inhibited by the non-selective Cl⁻ blocker NPPB (open circles). Unstimulated Cl⁻ efflux is demonstrated by the closed squares.

**Example 5: Chromogranin A immunoreactivity in CF tertiary bronchus.**

[0060] Cryostat section (5-7 μm) were cut from paraformaldehyde fixed, paraffin embedded sections of 5 CF and 3
non-CF tertiary bronchus, and stained with a mouse monoclonal chromogranin A antibody (Vector Laboratories Ltd; cat. No. NCL-CHROM), followed by IgG secondary antibody. The Vector Universal Elite ABC kit was used to detect antibody binding. Adjacent sections were incubated with a no primary negative control and appeared free of non specific binding. In CF tissue stained with the chromogranin A antibody, a number of solitary endocrine cells were observed, compared to little or no staining the normal tissue and controls. This indicates the presence of S-type enteroendocrine cells which are a target for modulators of secretin expression. Thus agents which stimulate secretin production in such cells may be used in the treatment of CF.

**Example 6: Endogenous regulation of secretin production.**

**[0061]** The mRNA expression of NeuroD in the tertiary bronchus and lung parenchyma in 17 normal and 25 CF lung donors was examined. Primer probe sets were specifically designed for the detection of NeuroD (accession number BAA76603). Off line homology searches revealed no significant matches with gene sequences logged at Genbank. Forward and reverse primer and probe sequences for the transcription factor BETA2/NeuroD were as follows:

<table>
<thead>
<tr>
<th>type</th>
<th>sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>forward primer</td>
<td>GAACGCGGCGCTAGACA (SEQ ID NO:7)</td>
</tr>
<tr>
<td>reverse primer</td>
<td>GTCTCGATTGTGGACAGCTCTG (SEQ ID NO:8)</td>
</tr>
<tr>
<td>probe</td>
<td>AGCAAGGCACCACCTTTGCA (SEQ ID NO:9)</td>
</tr>
</tbody>
</table>

**[0062]** Data (Figure 9) are expressed as mean \pm s.e. mean of the QRT-PCR threshold cycle, whereby the higher the threshold cycle, the lower the copy number of the gene per 100ng tRNA.

**[0063]** A significant reduction in NeuroD mRNA expression was observed in the CF parenchyma, with similar low abundance levels present in the tertiary bronchus of both control and CF donors. Functionally, this reduction in NeuroD in the CF parenchyma may correlate with a decreased regulation and synthesis of endogenous secretin. Enhancement of the functional expression of NeuroD may therefore lead to an enhancement in the endogenous levels of secretin within the lung, and therefore an indirect mechanism for the treatment of cystic fibrosis using agonism of the secretin receptor.

**[0064]** In summary, stimulation of the secretin receptor may be used to correct the ionic and H₂O problems of CF, reducing the thickness of the mucus layer, and allowing mucociliary clearance from the lung.

Claims

1. Use of camostat in the manufacture of a medicament for the treatment of cystic fibrosis (CF).

2. Use according to Claim 1 where the medicament is to be administered by inhalation.

3. Use according to Claim 2 wherein the inhalation administration is nebulization.
4. A composition comprising camostat together with at least one other compound active against CF, wherein the at least one other compound active against CF is chosen from nedocromil or mucolytic agents such as acetylcysteine, deoxyribonuclease I (dornase) or erdosteine.

Patentansprüche

2. Verwendung gemäß Anspruch 1, wobei das Medikament durch Inhalation zu verabreichen ist.
3. Verwendung gemäß Anspruch 2, wobei die Inhalationsverabreichung Zerstäubung ist.
4. Zusammensetzung, umfassend Camostat zusammen mit wenigstens einer anderen Verbindung, die gegen CF wirksam ist, wobei die wenigstens eine andere Verbindung, die gegen CF wirksam ist, ausgewählt ist aus Nedocromil und schleimlösenden Mitteln wie Acetylcysteine, Desoxyribonuclease I (Dornase) und Erdostein.

Revendications

1. Utilisation de camostat dans la fabrication d’un médicament pour le traitement de la mucoviscidose (CF).
2. Utilisation selon la revendication 1 dans laquelle le médicament est destiné à être administré par inhalation.
3. Utilisation selon la revendication 2 dans laquelle l’administration par inhalation est la nébulisation.
4. Composition comprenant du camostat conjointement avec au moins un autre composé actif contre CF, dans laquelle l’au moins un autre composé actif contre CF est choisi parmi le médocromil ou parmi des agents mucolytiques tels que l’acétylcystéine, la désoxyribonucléase I (dornase) ou l’erdostéine.
