Certain of the compounds of formula (I) may form acid addition salts with less than one or one or more equivalents of the acid, for example to form a dihydrochloride salt. The present invention includes within its scope all possible stoichiometric and non-stoichiometric forms. Salts having a non-physiologically acceptable anion or cation are within the scope of the invention as useful intermediates for the preparation of physiologically acceptable salts and/or for use in non-therapeutic, for example, in vitro, situations.

[0034] The compounds of formula (I) may be prepared in crystalline or non-crystalline form, and, if crystalline, may optionally be hydrated or solvated. This invention includes within its scope stoichiometric hydrates or solvates as well as compounds containing variable amounts of water and/or solvent.

[0035] Certain compounds of formula (I) are capable of existing in stereoisomeric forms (e.g. geometric (or "cis-trans") isomers, diastereomers and enantiomers) and the invention extends to each of these stereoisomeric forms and to mixtures thereof including racemates. The different stereoisomeric forms may be separated one from the other by the usual methods, or any given isomer may be obtained by stereospecific or asymmetric synthesis. The invention also extends to any tautomeric forms and mixtures thereof. The present invention includes within its scope all such isomers, including mixtures.

[0036] Compounds of formula (I) may be prepared according to procedures described herein, or by analogous procedures thereto.

[0037] A reaction route for a compound of formula (I) wherein m is 1 and R₁ is methyl, p is 0, n is 0, and q is 0, is as follows:

[0038] The above reaction scheme may be adapted to prepare compounds of formula (I) wherein m is other than 1, R₁ is other than methyl and in a position other than as illustrated above, and p, n and q are other than 0.

[0039] Compounds of formula (I) wherein Y and Z together form a C₃₋₇ cycloalkylene group may be prepared according to procedures described herein, or by analogous procedures thereto.

[0040] A typical reaction route for a compound of formula (I) wherein Y and Z together form a cyclopropylene group, and wherein m is 1 and R₁ is methyl, p is 0, n is 0, and q is 0, is as follows:
wherein X, R_3 and R_4 are as defined for formula (I). Thus, treatment of the piperazine described above with a 2-arylacetaldehyde produces an enamine, which can be treated under reaction conditions known to those skilled in the art, e.g. Simmons-Smith cyclopropanation reaction using diiodoethane and diethylzinc, to produce compounds of formula (I) wherein Y and Z together form a C_3-7-cycloalkylene group. The above reaction scheme may be adapted to prepare compounds of formula (I) wherein m is other than 1, R_1 is other than methyl and in a position other than as illustrated above, p, n and q are other than 0, and Y and Z form a C_3-7-cycloalkylene group other than cyclopropane.

Alternatively, the reaction of an aromatic nucleophile such as a Grignard reagent (M = MgX) or aryllithium (M = Li) with a cycloalkyl epoxide (where n=0,1,2), optionally in the presence of a catalyst e.g. a copper(I) halide, may provide an intermediate alcohol, as illustrated in the scheme below. The alcohol may conveniently be converted into a ketone using a suitable oxidising agent, e.g. pyridinium chlorochromate. The ketone may then be transformed to a compound of formula (I) using methods described in the preceding scheme.

The above scheme illustrates the case where p is 0, but may be adapted for cases where p is other than 0. Alternatively, the reaction of an aromatic nucleophile such as a Grignard reagent (M = MgX) or aryllithium (M = Li) with an α,β-unsaturated ketone (where n=1,2), in the presence of a catalyst e.g. a copper(I) halide, may provide a cycloalkyl ketone product. The ketone may then be transformed to a compound of formula (I) using methods described above.
The above scheme illustrates the case where \( p \) is 0, but may be adapted for cases where \( p \) is other than 0.

Alternatively, the treatment of a substituted 2-phenyl acetyl chloride with diazomethane may produce a regioisomeric mixture of the 1,2 and 1,3-cyclobutyl ketone derivatives (Synthesis, 1977, (6), 411). The ketone regioisomers may then be transformed to a compound of formula (I) using methods described above.

The above scheme illustrates the case where \( p \) is 0, but may be adapted for cases where \( p \) is other than 0.

Compounds of formula (I) can also be prepared according to the scheme below. Reaction of a substituted benzaldehyde with a reagent such as methoxymethyltriphenylphosphonium chloride in the presence of a suitable base, e.g. potassium carbonate or sodium methoxide or sodium hydride, produces an enol ether. The enol ether can be hydrolysed under acidic conditions, e.g. using aqueous hydrochloric acid optionally in a suitable co-solvent such as tetrahydrofuran, to give a substituted 2-phenylacetaldehyde derivative. The aldehyde can be reductively coupled to a 5-(1-piperazinyl)quinoline or quinazoline compound using conditions familiar to those skilled in the art e.g. using sodium triacetoxyborohydride or sodium cyanoborohydride. The product may be converted to a compound of formula (I) using
methods described previously (if the aromatic substituents do not already include a group of formula -NR₃R₄).

[0048] The above scheme illustrates the case where p is 0, but may be adapted for cases where p is other than 0.

[0049] Alternatively, compounds of formula (I) may be prepared according to the following scheme. Esterification of a 3-aminophenylacetic acid derivative under acidic conditions in an alcoholic solvent e.g. trimethylsilyl chloride in methanol produces the acetate ester hydrochloride. Reaction of the ester hydrochloride with a reagent such as a 2-halo-ethylisocyanate or a synthetic equivalent thereof, e.g. sequential addition of phosgene (or equivalent e.g. carboxydiimidazole, disuccinimidyl carbonate) and a 2-haloethylamine (Y=NH₂) or 2-haloethanol (Y=OH), optionally in the presence of a base, produces an intermediate where X is a leaving group as defined previously. Treatment of the intermediate with a strong base, such as sodium hydride, produces a cyclised product. Reduction of the ester group with a suitable reagent, for example lithium borohydride, produces a substituted 3-phenyl ethanol derivative. Conversion of the alcohol group to a sulfonate leaving group, such as by reaction with a sulfonic anhydride or sulfonyl chloride e.g. methanesulfonyl chloride, optionally in the presence of a suitable base, produces a compound, which can be converted to a compound of formula (I) according to the procedures described previously.
Thus, in a further aspect, this invention provides a process for the preparation of a compound of formula (I) or a pharmaceutically acceptable salt thereof, which process comprises the steps of:

(a) converting a compound of formula (III):

wherein $R_1$, $m$, $X$, $R_2$ and $n$ are as defined for formula (I), with a compound of formula (VIII):

$\text{(VIII)}$

wherein $W$, $p$, $Y$, $Z$, $R_5$, $q$, $R_3$ and $R_4$ are as defined for formula (I), and $L$ is a leaving group; or

(e) for a compound of formula (I) wherein $Z$ is $\text{-CH(OH)}$, reacting a compound of formula (VII) as defined in step (d) with a compound of formula (XIII):

$\text{(XIII)}$

wherein $W$, $p$, $Y$, $Z$, $R_5$, $q$, $R_3$ and $R_4$ are as defined for formula (I); or

(g) for a compound of formula (I) wherein the group W or Y attached to the nitrogen in the piperazine group in formula (I) is CH₂ or CH(C₁₋₆alkyl), reacting a compound of formula (VII) as defined above with a compound of formula (XV):

wherein R₃, R₄, R₅, q, Z, Y and W are as defined for formula (I), b is 0, 1 or 2 and Q is hydrogen or C₁₋₆alkyl; and thereafter optionally for any of steps (a) to (g):

- removing any protecting groups and/or
- converting a compound of formula (I) into another compound of formula (I) and/or
- forming a pharmaceutically acceptable salt.

[0051] In step (a), a compound of formula (III) is converted to form a compound of formula (I) by standard reduction reactions known to the skilled person, for example by reaction with iron and NH₄OH to form a compound of formula (I) wherein R₃ and R₄ are both hydrogen. Such compounds may then be converted to other compounds of formula (I) as described below. Compounds of formula (III) may be prepared according to procedures described herein, by known literature methods, or by analogous procedures thereto.

[0052] A compound of formula (I) wherein Y and Z form a cyclopropane group may be made by step (b), by conversion of a compound of formula (IV). As noted above, the conversion reaction may be for example a Simmons-Smith reaction. Compounds of formula (IV) may be prepared according to procedures described herein, by known literature methods, or by analogous procedures thereto. For example, compounds of formula (IV) may be made by reacting a compound of formula (VII) as defined above with a compound of formula (XVI):

wherein p, W, R₃, R₄, R₅ and q are as defined for formula (I).

[0053] In step (c), a compound of formula (V) is reacted with a compound of formula (VI). The reaction may take place under conditions known to those skilled in the art, for example optionally in the presence of a copper-based catalyst.
Compounds of formula (V) may be prepared according to procedures described herein, by known literature methods, or by analogous procedures thereto.

In step (d), a compound of formula (VII) is reacted with a compound of formula (VIII). Suitable reaction conditions for step (d) include the use of a base, for example triethylamine or N,N-diisopropylethylamine, in a suitable solvent such as dimethylformamide, acetonitrile, dimethylsulfoxide or N-methylpyrrolidinone with optional heating of the reaction to a temperature between 30 and 200 °C, preferably between 50 and 150 °C.

Compounds of formula (VIII) may be prepared for example by converting a compound of formula (XVII):

wherein W, p, Y, Z, R₃, R₄, R₅ and q are as defined for formula (I), to introduce the leaving group L by for example reacting with MeSO₂Cl.

The present invention provides a process for the preparation of a compound of formula (Ia) as defined above or a pharmaceutically acceptable salt thereof, which process comprises the step of reacting a compound of formula (XVIII):

wherein R₁, m, X, Y, p, Z, R₅ and q are as defined for formula (Ia) above, with compound(s) containing appropriate functional group(s) which is/are capable of reacting with a compound of formula (XVIII) to form a compound of formula (I). Compounds of formula (XVIII) may be prepared according to procedures described herein, by known literature methods, or by analogous procedures thereto.

Compounds of formula (I) can be converted into further compounds of formula (I) using standard techniques. For example, and by way of illustration rather than limitation, possible conversion reactions include acylation with an appropriate acetylating agent such as acetyl chloride, alkylation using an appropriate alkylating reagent such as methyl iodide, and sulfonylation using a sulfonylating agent such as methanesulfonylic anhydride. For example, for a compound of formula (I) wherein R₃ and R₄ are independently C₁₋₆alkylsulfonyl, a compound of formula (I) wherein R₃ and R₄ are both hydrogen may be reacted with a C₁₋₆alkylsulfonyl chloride. For a compound of formula (I) wherein R₃ and R₄ are

Independently formula (II), a compound of formula (I) wherein R₃ and R₄ are both hydrogen may be reacted with a compound of formula (XIX):

![Chemical Structure](image)

wherein r, A, B, D and E are as defined for formula (II) above, and Q is a suitable leaving group such as chlorine, or is -OH when r is zero. To obtain a compound of formula (I) wherein B is -NR₅, an appropriate isocyanate or isothiocyanate may be used. On the other hand, for compounds of formula (I) wherein R₃ and R₄ are attached, a 3-7 membered monocyclic heterocyclic group, an appropriate chloroformate or an isocyanate may be used to react with a compound of formula (I) wherein R₃ and R₄ are both hydrogen.

[0060] It will be appreciated by those skilled in the art that it may be necessary to protect certain reactive substituents during some of the above procedures. Standard protection and deprotection techniques, such as those described in Greene T.W. Protective groups in organic synthesis, New York, Wiley (1981), can be used. For example, primary amines can be protected as phthalimide, benzyl, t-butyloxycarbonyl, benzoxycarbonyl or trityl derivatives. Carboxylic acid groups can be protected as esters. Aldehyde or ketone groups can be protected as acetals, ketals, thioacetals or thioketals. Deprotection of such groups is achieved using conventional procedures well known in the art. For example, protecting groups such as t-butyloxycarbonyl may be removed using an acid such as hydrochloric or trifluoroacetic acid in a suitable solvent such as dichloromethane, diethylether, isopropanol or mixtures thereof.

[0061] Pharmacologically acceptable salts may be prepared conventionally by reaction with the appropriate acid or acid derivative.

[0062] The affinities of the compounds of this invention for 5-HT₁A, 5-HT₁B and 5-HT₁D receptors can be determined by the following assay. CHO cells expressing 5-HT₁A receptors (4 x 10⁷ cells/ml) are homogenised in Tris buffer and stored in 1 ml aliquots. CHO cells expressing 5-HT₁B receptors (4 x 10⁷ cells/ml) are homogenised in Tris buffer and stored in 1.5 ml aliquots. CHO cells expressing 5-HT₁D receptors (1 x 10⁸/ml) are homogenised in Tris buffer and stored in 1 ml aliquots. 0.4 ml of a cell suspension is incubated with [³H]-5-HT (4nM) for 5-HT₁B/₁D receptors and [³H]WAY 100635 (1 nM) for 5-HT₁A receptors in Tris Mg HCl buffer (pH 7.7) and test drug, at 37°C for 45 minutes. Each test drug is tested at 10 concentrations (0.01 mM to 0.3 nM final concentration), with non-specific binding defined using 0.01 mM 5-HT. The total assay volume is 0.5 ml. Incubation is stopped by rapid filtration using a Packard Filtermate and radioactivity measured by Topcount scintillation counting. pKi values are calculated from the IC₅₀ generated by an iterative least squares curve fitting programme.

[0063] Alternatively, functional potency can be measured by the following GTPγS binding protocol. Cells used in the study are Chinese Hamster Ovary (CHO) Cells, Human Embryo Kidney (HEK293). Cells were transfected with DNA coding for human receptors.

Cell Line

Comounds were initially dissolved in 100% Dimethyl Sulphoxide at a concentration of 10mM. Serial dilutions of drugs in 100% Dimethyl Sulphoxide were carried out using a Biomek FX. The final top concentration of compound was 3µM in the assay. The compound at 1.0% total assay volume (TAV) was added to a solid, white, 384 well assay plate (Costar), 50%TAV of precoupled (for 90 mins @ RT) membranes, 5μg/well, and Wheatgerm Agglutinin Polystyrene Scintillation Proximity Assay beads (TRNPQ0260 Amersham International), 0.25mg/well, in 20mM HEPES pH 7.4, 100mM NaCl, 3mM MgCl₂ and 10μM GDP was added. The third addition was a 20% TAV addition of either buffer, agonist format, or EC₅₀ final assay concentration (FAC) of agonist, 5HT antagonist format, prepared in assay buffer. The assay was started by the addition of 29%TAV of GTP[S] 0.38nM FAC. After all additions assay plates were incubated at RT for 2-3 hours. Assay plates were counted on a Viewlux, 613/55 filter for 5 mins. Assay plates were read between 2-6 hours after the final addition.

[0065] The Example compounds shown below were tested and were found to have pKi values > 6.0 at 5-HT₁A receptors, with many showing a considerably higher affinity (having pKi values in the range 8.0 - 10.0) Certain compounds of this invention also demonstrate comparable affinity for 5-HT₁B and 5-HT₁D receptors.

[0066] The intrinsic activity of the compounds of this invention can be determined according to the following assay. HEK293 cell membranes stably expressing human 5-HT₁A receptors and CHO cell membranes stably expressing human
5-HT\textsubscript{1B} receptors are homogenised in HEPES/EDTA buffer and stored in 1 ml aliquots, and \[^{[35]}\text{S}\]GTP\textsubscript{S} binding studies are carried out essentially as described by Lazareno et al. (Life Sci., 1993, 52, 449) with some minor modifications. Membranes from 10\textsuperscript{6} cells are pre-incubated at 30°C for 30 minutes in 20 mM HEPES buffer (pH 7.4) in the presence of MgCl\textsubscript{2} (3 mM), NaCl (100 mM), GDP (10 \(\mu\)M) and ascorbate (0.2 mM), with or without test compounds. The reaction is started by the addition of 50 \(\mu\)l of \[^{[35]}\text{S}\]GTP\textsubscript{S} (100 pM, assay concentration) followed by a further 30 minutes incubation at 30°C. Non-specific binding is determined using nonradiolabelled GTP\textsubscript{S} (20 \(\mu\)M) added prior to the membranes. The reaction is terminated by rapid filtration through Whatman GF/B grade filters followed by 5 x 1 ml washes with ice cold HEPES (20 mM)/MgCl\textsubscript{2} (3 mM) buffer. Radioactivity is measured using liquid scintillation spectrometry. This procedure is hereafter referred to as the \[^{[35]}\text{S}\]GTP\textsubscript{S} functional assay.

[0067] It has been found, using the \[^{[35]}\text{S}\]GTP\textsubscript{S} functional assay, that certain compounds of formula (I) appear to be antagonists at 5-HT\textsubscript{1B} type receptors whilst others appear to be inverse agonists, agonists or partial agonists.

[0068] The efficacy of the compounds of this invention to inhibit the re-uptake of serotonin can be measured in a 5-HT uptake assay by measurement of uptake of \[^{[3]}\text{H}\]-5-HT into LLC-PK\textsubscript{1} cells expressing human or rat serotonin transporters. In brief, cells are harvested and plated onto 96-well plates (10,000 cells per well). 24 hr later cells are washed 2x with HBSS (Hanks’ balanced salt solution + 20 mM HEPES). 50\(\mu\)l of test compound or vehicle is added to each well and incubated for 10 min. Subsequently, \[^{[3]}\text{H}\]-5-HT (final concentration 25nM) is added and the test mixture is incubated for a further 7 min. The reaction is terminated by aspiration of test mixture and the cells are washed 6x with HBSS. 50\(\mu\)l of scintillation cocktail (Microscint-20, Packard) is added onto the cells and the top and bottom of the plate is sealed. Plates are read, 30 min later, in a Packard TopCount.

[0069] Alternatively: the potency of the compounds to bind the re-uptake site of serotonin may be assessed using \[^{[3]}\text{H}\]citalopram binding assays performed in recombinant epithelial pig kidney cells stably transfected with human SERT (hSERT/LLCPK). The cells were grown onto Petri dishes of 500cm\textsuperscript{2}. At 80% of confluence the cells were harvested in phosphate buffered saline (PBS) containing 5mM EDTA and centrifuged at 900g for 8 min at 4°C. The pellet was homogenised in 30-50 vols of assay buffer (50mM Tris, 120mM NaCl, 5mM KCl, 10\(\mu\)M Pargyline, 0.1% Ascorbate (pH=7.7)) and centrifuged at 48000g for 20min at 4°C. The pellet was resuspended in the same volume and after incubation at 37°C for 20 min, centrifuged as before and finally aliquoted at -0.2mg protein/ml in cold assay buffer. \[^{[3]}\text{H}\]citalopram binding assays consisted of 100\(\mu\)l of test compound, assay buffer (to define total binding) or a final concentration of 10\(\mu\)M paroxetine (to define non-specific binding), 100\(\mu\)l of [\[^{[3]}\text{H}\]Citalopram at final concentration of 0.25nM and 200\(\mu\)l of membranes diluted in assay buffer at concentration of 2\(\mu\)g/well of protein. Membranes were added last to initiate the reaction and incubated at room temperature for 2h. The reaction was then stopped by rapid filtration through GF/B 96-filterplate pre-soaked in 0.5% polyethylenimmine (PEI) using a Packard cell harvester. 96-filterplate was washed 3 times with 1 ml/well cold 0.9% NaCl solution and the radioactivity was counted in Packard TopCount.

[0070] Some of the Example compounds tested according to this uptake assay were found to have potency at the uptake site of pIC\textsubscript{50} of > 6.0.

The crude material was purified on SPE cartridge (Silica) using a gradient from dichloromethane to dichloromethane/MeOH 95/5 as eluant affording the final compound (yields ranged from 30 to 80%).

[0175] The free base could be converted into its dihydrochloride salt by dissolving the compound in Et2O and MeOH and adding an 1 M ethereal solution of HCl (2.1 eq) dropwise. A yellow solid precipitated and the suspension was stirred for 15 min. The solvent was removed under reduced pressure affording a crude material which was triturated with Et2O. The final compound was then recovered by filtration (yield quantitative).

General procedure for the preparation of ureas and their corresponding dihydrochloride salts starting from 3-[2-[4-(2-methyl-5-quinolinyl)-1-piperazinyl]ethyl]aniline(D6): Method F

[0176] Triethylamine (6 eq) and solid triphosgene (0.5 eq) were in added sequentially to a stirred solution of 3-[2-[4-(2-methyl-5-quinolinyl)-1-piperazinyl]ethyl]aniline (D6) (1 eq) in dichloromethane at 0°C under an inert atmosphere. The reaction mixture was left under stirring for 1 h then diisopropylethylamine and an amine (1.1 eq) dissolved in CH3CN were added dropwise. The solution was stirred for 16 h then diluted with dichloromethane, washed with saturated aqueous solutions of NaHCO3 and brine and dried over Na2SO4. The solution was concentrated under reduced pressure affording a crude material which was triturated with Et2O. The final compound was then recovered by filtration (yield quantitative).

General procedure for the synthesis of cyclic ureas and carbamates and their corresponding dihydrochloride salts starting from 3-[2-(4-methyl-5-quinolinyl)-1-piperazinyl]ethyl)aniline (D3): Method G

[0211] Diisopropylethylamine (1.5 eq) and a chloroformate or isocyanate (1.2eq) were added sequentially to a stirred solution of 3-[2-(4-methyl-5-quinolinyl)-1-piperazinyl]ethyl)aniline (1 eq) in dichloromethane at 0 °C. The solution was stirred for 1 hr at room temperature, then diluted with dichloromethane and washed with a saturated aqueous solution of NH_{4}Cl and brine and then dried over Na_{2}SO_{4}. The solution was concentrated under reduced pressure. The crude material was dissolved in dimethylformamide, cooled to 0 °C, and NaH (1.1 eq) was added portionwise under an inert atmosphere. The mixture was stirred for 2 hrs at room temperature, then the solvent was removed by means of an SCX cartridge. The crude material was purified on SPE cartridge (Silica) eluting with a gradient from dichloromethane/MeOH 99/1 to dichloromethane/MeOH 98/2 affording the final compound (yields ranged from 22 to 87%).

[0212] The free base could be converted into its dihydrochloride salt by dissolving the compound in Et_{2}O and MeOH and adding an 1 M ethereal solution of HCl (2.1 eq) dropwise. A yellow solid precipitated and the suspension was stirred for 15 min. The solvent was removed under reduced pressure affording a crude material which was triturated with Et_{2}O. The final compound was then recovered by filtration (yield quantitative).
