A prosthetic cup adapted to be held in place in a receptive opening in a bone by cement, and having an outer surface provided with one or more projecting spacers to space said outer surface away from the surface of said receptive opening and in which said spacer or spacers is or are loosely carried on said cup with a surrounding clearance gap to allow loose relative movement in all directions.

![Diagram of a prosthetic cup with spacers](image)
This invention relates to a cement spacer which can be used in a prosthetic cup and to a method of sterilization thereof.

Prosthetic cups adapted to be held in place in a receptive opening in a bone can have an outer surface provided with one or more projecting cement spacers to space the outer surface of the cup away from the receptive opening in which it is placed. The resulting gap around the cup provided by the spacer or spacers enables the thickness of cement to be controlled. Spacers of this type are well known for this purpose such as shown in US Patents Nos. 4,563,778 and 4,955,325.

The spacers can be provided in many ways but are often formed as projections on the outer surface of, for example, a prosthetic hip cup.

Products for use in surgery require sterilization and cups made from, for example, polyethylene can be sterilized with a gas plasma sterilization process. With this process the gas has to be present on all the surfaces of the product to sterilize it. There can be problems with sterilizing polyethylene cups at a level of the cement spacer which can be located in a receptive opening in which it is placed. The resulting gap around the cup provided by the spacer or spacers enables the thickness of cement to be controlled. Spacers of this type are well known for this purpose such as shown in US Patents Nos. 4,563,778 and 4,955,325.

The present invention is intended to provide a construction of cement spacer which can be located in a cup but still provide the facility for sterilization.

According to the present invention a prosthetic cup adapted to be held in place in a receptive opening in a bone by cement, and having an outer surface spaced from the receptive opening in which it is placed. The resulting gap around the cup provided by the spacer or spacers enables the thickness of cement to be controlled. Spacers of this type are well known for this purpose such as shown in US Patents Nos. 4,563,778 and 4,955,325.

The present invention includes a method of sterilizing a prosthetic cup of the kind set forth above which includes applying a gas plasma with a pressure which is sufficient to enter the gap surrounding the spacer to allow the gas to sterilize the walls of the gap and the spacer.

Various aspects of the invention are accomplished by an acetabular cup which has a shell having a recess therein. The recess is open to an outer surface of the shell and has an enlarged portion spaced from the outer surface having a diameter greater than the diameter of the opening at the outer surface. An insert is provided for insertion into the recess in the outer shell. The insert has a height greater than a depth of the recess and has a solid portion and a bifurcated portion having at least two side openings thereby forming two to four sectors. A base of each sector of the bifurcated portion having an outwardly extending flange for insertion into the enlarged portion of the recess. The base of the bifurcated portion may include a plurality of outwardly extending feet for engaging a bottom surface of the recess. The bifurcated portion can have four side openings forming four deflectable arms. Each arm preferably includes a foot for engaging the bottom surface of the recess and spacing the insert therefrom. The flange preferably has an inwardly chamfered outer surface to facilitate insertion into the recess. The solid insert portion may have a bore therein extending from the outer surface of the insert to an intersection of the side openings in the bifurcated insert opening. Preferably the outer cup surface includes at least three inserts located in corresponding recesses in the shell.
cup.

[0021] The invention can be performed in various ways but one embodiment will now be described by way of example and with reference to the accompanying drawings in which:

Figure 1 is a diagrammatic side view of a prosthetic hip cup made from polyethylene and incorporating cement spacers according to the present invention;

Figure 2 is a side view of a cement spacer according to the invention in position in the outer surface of the cup shown in Figure 1;

Figure 3 is a diagrammatic isometric view from above of the spacer shown in Figure 2;

Figure 4 is an isometric view from below of the spacer shown in Figures 2 and 3;

Figure 5 is a cross-section diagrammatic view of an alternative construction; and,

Figure 6 is a cross-section diagrammatic view of another alternative construction.

[0022] As shown in Figures 1 to 4 of the drawings the prosthetic insert which is adapted to be held in place in a receptive opening in a bone by cement, according to the present invention, is in the form of an acetabular cup 1 which is formed from polyethylene. The outer surface 2 of the cup 1 is provided with four projecting spacers 3 which can act to space the outer surface 2 away from the surface of a receptive opening 4 the surface of which is indicated by chain line 5 in Figure 2.

[0023] Each of the spacers 3 comprises a head 6 which projects from the outer surface 2 and a location portion 7 which is carried in a recess 8 with a surrounding clearancegap 9.

[0024] The recess 8 is undercut at 10 and the location portion 7 has a retention flange 12 which locates within the undercut 10.

[0025] The dimensions of the flange and the undercut are arranged so that the spacer is a snap-fit but is loose so that there is relative movement in all directions.

[0026] The width of the gap 9 around the location portion 7, including the flange 12, is between 1 mm and 0.01 mm.

[0027] The lower surface of the location portion 7 carries four abutment feet 13 which project downwardly below the flange 12 and which, when the spacer is initially inserted, rest on the bottom of the recess 8. Due to the gap however, and as mentioned above, the spacer is loosely carried and can be moved in all directions including the feet 13 moving away from the lower surface of the recess 8.

[0028] The outer end of the head 6 has an opening 14 which extends inwardly into the recess 8 via a chamber 15 which extends through the inner end of the location portion 7. The chamber 15 has four side openings 16 (best shown in Figure 4) which extend through the side wall of the location portion 7 and into a part of the side wall of the head 6.

[0029] The outer end of the head 6 is substantially dome-shaped and the insert portion 7 is substantially cylindrical.

[0030] The lower end of the flange 12 is chamfered as indicated by reference numeral 17 and the outer end of the recess 8, which is circular to take the flange 12, is also chamfered at 18. This chamfering assists the snap-fit.

[0031] Figure 5 shows an alternative construction in which spacer 20 comprises a head portion 21 and an engagement portion 22 which has a recess 23 the outer edge 24 of which has an inwardly projecting flange 25 which is dimensioned to loosely engage beneath an undercut 26 on a co-operating abutment 27 provided on the outer surface 28 of an insert 29. A clearance gap 30 is provided between the abutment 27 and the inner surface 31 of the recess 23 and the spacer therefore engages loosely on the abutment 27 with a snap-fit.

[0032] The clearance gap can be between 1 mm and 0.01 mm.

[0033] The abutment 27 is provided with four abutment feet 32 to space it away from the inner surface 31 of the recess 23.

[0034] The outer end of the head 21 of the spacer has an opening 33 which extends into the recess 23.

[0035] This construction can be used in a similar manner described in the construction shown in Figures 1, 2 and 3.

[0036] Figure 6 shows an alternative construction similar to that shown in Figure 5 and the same reference numerals are used to indicate similar parts. In this construction the abutment feet 32 are replaced by feet 34 which are provided on the inner surface 31 of the recess 23 to provide a gap 30.

[0037] The invention also includes a method of sterilizing a prosthetic cup of the type described above and which includes applying a gas plasma in a suitable environment with a pressure which is sufficient to enter the gap 8 between the spacer 3 and the insert 1 or into the gap 30 between the abutment 27 and the spacer 20 to allow the gas plasma to sterilize the walls of the gap and the spacer, at the same time as sterilizing the insert.

[0038] The various parts can be made of any convenient material, for example a synthetic plastics material, a metal or a bone cement (PMMA) and in the embodiments described the cup 15 is made of a polyethylene material.

[0039] The invention therefore provides an arrangement whereby the retentive shape of spacer can be used to ensure a good fixation and the various features help the gas to penetrate behind and on the sides of the spacer.
Claims

1. A prosthetic cup adapted to be held in place in a receptive opening in a bone by cement, and having an outer surface provided with one or more projecting spacers to space said outer surface away from the surface of said receptive opening and in which said spacer or spacers is or are loosely carried on said cup with a surrounding clearance gap to allow loose relative movement in all directions.

2. A prosthetic cup as claimed in claim 1 in which each of said spacers comprise a head which projects from said outer surface and a location portion which is carried in a recess in said cup with a surrounding clearance gap.

3. A prosthetic cup as claimed in claim 2 in which said clearance gap is between 0.01 mm and 1 mm.

4. A prosthetic cup as claimed in claim 2 or claim 3 in which said recess is undercut and said location portion has a retention flange which locates in said undercut location portion.

5. A prosthetic cup as claimed in claim 4 in which said retention flange has a diameter slightly greater than the inner edge of said undercut so that the flange can be pressed into position with the flange locating beneath the undercut location portion.

6. A prosthetic cup as claimed in claim 5 in which said location portion locates beneath the retention flange as a snap fit.

7. A prosthetic cup as claimed in claim 6 in which said inner end of said location portion has one or more abutments feet to space it away from the inner end wall of the recess.

8. A prosthetic cup as claimed in claims 2 to 7 in which the outer end of the head has an opening which extends inwardly into the recess.

9. A prosthetic cup as claimed in claim 8 in which said opening extends into a chamber extending through the inner end of the location portion.

10. A prosthetic cup as claimed in claim 9 in which said chamber has a side opening or openings which extend through the side wall of the location portion.

11. A prosthetic cup as claimed in claim 10 in which said openings extend into a part of the side wall of the head.

12. A prosthetic cup as claimed in claim 1 in which said spacers comprise a head portion and an engagement portion, which has a recess the outer edge of which has an inwardly projecting flange which is dimensioned to loosely engage beneath an undercut on a co-operating abutment provided on the outer surface of the insert to provide a clearance gap between them and locate on said abutment with a snap fit.

13. A prosthetic cup as claimed in claim 12 in which said clearance gap is between 0.01 mm and 1 mm.

14. A prosthetic cup as claimed in claim 12 or claim 13 in which said abutment is provided with one or more abutment feet to space it away from the inner end wall of the recess.

15. A prosthetic cup as claimed in any one of preceding claims 12 to 14 in which the outer end of the head of the spacer has an opening which extends into the recess.

16. A prosthetic cup as claimed in any one of the preceding claims in which the spacer is made from a compatible metal or synthetic plastics material.

17. A prosthetic cup as claimed in any one of the preceding claims in which the end of the spacer or each of the spacers is dome shaped.

18. A prosthetic cup as claimed in any one of the preceding claims in which the inert portion is substantially cylindrical.

19. A method of sterilizing a prosthetic cup as claimed in any one of the preceding claims which includes applying a gas plasma with a pressure which is sufficient to enter the gap surrounding the projecting spacer or spacers to allow gas plasma to sterilize the walls of said gap and said spacer.
