Flexible container with insert part

A flexible container (1) for storing a liquid medicament comprises a container wall consisting of two wall sheets (101, 102) of flexible material that are sealed together (13, 14). The container (1) comprises a storage compartment (11) for the liquid medicament, and an access opening (121) on one of the wall sheets (101). The storage compartment (11) and the access opening (121) are in fluid connection. The access opening (121) is designed to be fluidly connected to an outer conduit system (33). An insert part (2) is arranged between the two wall sheets (101, 102) with positive locking, and fluidly connects (22, 23, 221) the storage compartment (11) and the access opening (121).

(a)
Description

Field of the Invention

[0001] The invention relates to a flexible container for storing a liquid medicament to be administered to a patient by an infusion pump device, an insert part for use with such a flexible container, and a device for the automated release of a liquid medicament, comprising, incorporating, and/or capable of using such a flexible container, according to the preambles of the independent claims.

State of the art

[0002] Devices for the automated release of liquid medicaments are normally used with patients who have a continuous and in the course of the day varying need of a medicine which can be administered by subcutaneous infusion. Specific applications are, for example, certain pain therapies and the treatment of diabetes, in which computer controlled infusion pump devices, such as insulin pumps, are used. Such devices can be carried by a patient on the body, and contain a certain amount of liquid medicament in a medicine reservoir in the form of a container. The medicine reservoir often comprises medicine sufficient for one or several days. The liquid medicament is supplied to the patient’s body from the medicine reservoir through an infusion cannula or an injection needle.

[0003] Particularly in self-administration of medicaments, for example insulin, the patients using the medicament in question and administering it themselves by means of an infusion pump are increasingly emphasizing convenience and discretion. As a consequence the dimensions of such infusion devices are limited, and particularly the overall length, width and thickness should be as small as possible, in order not be evident through clothing and to be carried as comfortable as possible.

[0004] While there are fully or partly disposable single-use infusion pump devices, such devices are typically non-disposable and are loaded with a disposable drug cartridge. Disposable cartridges are preferable for sterility and contamination prevention reasons. They may be delivered pre-filled with a certain liquid medicament, or empty, ready to be filled by a user. Said self-filling of containers has the advantage that also medicaments that are not readily available in pre-filled containers can be used for such infusion pump devices, thereby providing the patient with a larger choice of sources for his medicaments. Furthermore the stability of many medicaments in liquid form, particularly in plastic containers, can only be guaranteed by the manufacturer for some days.

[0005] The standard infusion pump devices that are carried on or near the body have a medicine reservoir with a cylindrical ampoule and a displacement piston, which is pushed into the ampoule by a piston rod or threaded spindle in order to convey the liquid medicament. These known designs have the disadvantage of being longer and/or thicker than desired, the resulting dimensions being detrimental to the provision of compact infusion pumps.

[0006] Manufacturers try to meet the demand of small infusion pump devices by various means. For example the infusion pump can be divided into structural assemblies which are each arranged in their own, smaller, housings and can be joined to one another by wireless or wired connection. An example of such a modular infusion pump device is disclosed in US 2006/0184119 A1.

[0007] Another possibility is the use of containers of particularly flat construction. For example may the cylindrical ampoule be replaced by a container with a rectangular or another suitable cross-section, interacting with a displacement piston of corresponding shape. Different embodiments of such compact medicine reservoir devices are shown in WO 2008/122135A1.

[0008] A further approach to reduce the overall volume of an infusion pump device is to replace the syringe-type dosing mechanism, in which a piston is displaced along a long container axis by an actuator, thereby conveying the appropriate amount of liquid medicine, by a downstream pump system. In such a device a miniaturized pump is arranged downstream of the reservoir, and causes a suction pressure that conveys the product from the reservoir to its destination. An example for such a pump is WO 2004/009162A1.

[0009] For some of such infusion pump devices, the suction pressure achievable with such a pump system is not very high. A suitable container for such devices is disclosed in US 2007/0123820 A1, comprising a flat container and a flat piston body arranged in the body in a sliding manner. Fully filled, such a container has a ratio between its maximum height and its overall width of less than 1.25. The cross-section area of the container in relation to the displacement axis is much larger than for conventional cylinder-piston arrangements, and already a comparably small pressure gradient as generated by a miniaturized pump is able to overcome the friction force of the piston sealing gliding on the inner container wall.

[0010] In an especially advantageous approach the rigid container and movable piston are replaced by a flexible container. Such a flexible container may for example have the form of two flexible wall sheets that are sealed together. Flexible containers have the advantage of a smaller volume surplus of the container in relation to its content, which reduces the manufacture costs and the achievable dimensions of an infusion pump device using such a flexible container. The volume of a flexible container for use in an infusion pump device may be up to 10 ml, for example. A typical range for diabetes therapy is 1.5 to 3.5 ml. For other therapies, e.g. pain therapy, which require other administration regimes, other volume ranges may be more preferable.

[0011] For use in an infusion pump device the flexible container must be connected to a conduit system of the device. For that purpose the flexible container may be provided with a port. Such a port can be mounted on the
container with a flange sealed to a container wall sheet. US 2007/0049865 A1 discloses such a container. The port is provided with a septum, to be punctured by a hollow needle of the conduit system of the infusion pump device. Another possibility used for flexible containers are ports in the form of flexible tubes or rigid connection pieces welded between the two sheets of the container at the periphery of the flexible container. The fastening of the port to the container, for example by gluing or welding, requires a precise production control to avoid high rejection rates, and furthermore limits the choice of suitable materials.

A common problem of flexible containers with ports as used, for example, in IV bags, is the dead volume resulting between the collapsed container and the port. Said dead volume cannot be used, meaning that it cannot be emptied. Thus a complete drainage of the contents of a flexible container is not possible. The resulting loss of useable container volume due to the dead volume is particularly high for smaller containers as they are suitable for infusion pumps, with a total volume of only 5 ml or less. In standard liquid medicament containers for infusion pump devices the dead volume may lie in the range of at least 5% of the overall volume. For flexible containers according to the invention, the remaining dead volume lies in a range of 1 to 2% or less. For single-use container filled with the medicament, the dead volume considerably increases the effective costs per dose and thus of the overall therapy costs, since a certain percentage of the medicament will inevitably remain in the container and has to be disposed. This cost effect is particularly important for expensive medicaments. In addition to the increased costs, the dead volume leads also to an increase of the overall volume of the flexible container, and thus of the infusion pump device with such a flexible container.

A further problem, particularly of flexible containers as they are known, is air remaining in the container. If for example a flexible container is provided empty, intended to be filled with the appropriate medicament by the user himself, the dead volume is initially filled with air. However, removing the air from flexible containers as they are known from the state of the art will require a certain skill of a user. If said air remains in the container or in the fluidic system of a pump system, air bubbles may be administered instead of the liquid medicament, which leads to potentially dangerous dosing errors.

Furthermore the administration of air into a patient’s body should generally be avoided for medical reasons.

Yet another problem of air in the fluidic system is the reduced stiffness of the fluidic system. Due to the high compressibility of gases such as air in relation to liquids such as water, it becomes difficult to measure the exact pressure in the fluidic system. This impedes the detection of blockages or occlusions in the fluidic system of an infusion pump device by measuring the fluidic pressure.

Objects of the Invention

One object of the invention is to provide a flexible container for storing a liquid medicament to be administered to a patient, which does not comprise the disadvantages of the known containers. Particularly a flexible container according to the invention should be easily connected to a device for the automated release of a liquid medicament. Furthermore a flexible container according to the invention should have a reduced dead volume, and should be easily connected to a device for the automated release of a liquid medicament. It should also have dimensions that are suitable for being carried on or near the body.

In addition a flexible container according to the invention should be producible with high quality at low costs, and should comprise a minimum number of components.

A further object of the invention is to provide advantageous insert parts for use in such flexible containers, which allow to fluidly connecting the flexible container with a connection device for connecting a flexible container with a device for the automated release of a liquid medicament.

Yet another object of the invention is to provide a device for the automated release of a liquid medicament comprising, incorporating, and/or capable of using such a flexible container.

These and other objects are achieved by a flexible container, an insert part, and an infusion pump device, according to the independent claims. Advantageous embodiments are given in the dependent claims.

Summary of the invention

A flexible container for storing a liquid medicament according to the invention comprises a container wall consisting of two wall sheets of flexible material that are sealed together. The container comprises a storage compartment for the liquid medicament, and an access opening on one of the wall sheets. The storage compartment and the access opening are in fluid connection, and the access opening is designed to be fluidly connected to an outer conduit system. An insert part is arranged between the two wall sheets with positive locking, and fluidly connects the storage compartment and the access opening.

The access opening of the flexible container is intended to be fluidly connected to an outer conduit system of an infusion pump device either directly or using a suitable connection device.

The positive locking is achieved by the interaction of elements of the insert part with elements of the wall sheets. For example the periphery of the insert part may be positively locked between the two adjacent wall sheets and the sealing rim of the wall sheets. In such a case the direction of the locking force is essentially parallel to the wall sheets. The insert part may have some
play parallel to the wall sheets, as long as the fluid connection between the storage compartment and the access opening via the insert part is given.

[0024] In an advantageous embodiment of a flexible container according to the invention the insert part is arranged and positively locked in a distinct access area of the container.

[0025] Preferably said access area is separated from the storage compartment by a neck or constriction.

[0026] In another advantageous embodiment of a flexible container according to the invention elements are provided for positioning and/or fixing the flexible container in a connection device, particularly in a connection device of an infusion pump device, particularly in a connection device of an infusion pump device.

[0027] Preferably said elements for positioning and/or fixing are two or more holes and/or grooves and/or protrusions arranged in a sealed area of the container, and/or in an area of the wall sheets outside of the sealed area that does not belong to the storage compartment.

[0028] In yet another advantageous embodiment of a flexible container according to the invention the access opening comprises a hole arranged in a wall sheet adjacent to the insert part, preferably above an opening of a conduit system of the insert part. The access opening may for example have a diameter of about 1.5 mm or less. In said embodiment of the flexible container the insert part may comprise a sealing lip arranged on the upper surface of the insert part, wherein the sealing lip protrudes through the hole of the access opening.

[0029] In a preferred variant of said embodiment of the flexible container the positive locking of the insert part in the flexible container is at least partially achieved by the sealing lip protruding through the hole of the access opening.

[0030] A flexible container according to the invention may preferably include a connection device for use in an infusion pump device, comprising two clamp parts that are adapted to positively and/or non-positively locking the flexible container, and to fluidly connecting an access opening of the flexible container to a conduit system of the connection device. Typically, in such a variant of a flexible container the access opening is not directly accessible. Preferably the flexible container and the connection device are provided as a compact pre-assembled unit.

[0031] In a preferred embodiment of such a flexible container the clamp part facing toward the access opening comprises a sealing element that is adapted to fluidly connecting the conduit system with the access opening of the flexible container.

[0032] In another preferred embodiment of such a flexible container the surface of the clamp parts of the connection device is adapted to the exterior shape of the flexible container, particularly to the exterior shape of an access area of the container.

[0033] Additionally or alternatively one or both clamp parts may also comprise resilient elements directed towards the opposite clamp part, in order to increase the friction-lock of the container or to improve the sealing.

[0034] The connection device may comprise further functional elements, such as for example a bubble trap, a pressure sensor, or a pressure transfer membrane for coupling a conduit system of the connection device to a pressure sensor. It may also comprise a pumping/dosing mechanism, or part of a pumping mechanism, such as a micro membrane pump, or a micro plunger pump.

[0035] In a particularly preferred embodiment of a container according to the invention, the container comprises a bubble trap. Said bubble trap may be an integral part of the container, fully or in part. More preferably it may comprise a bubble trap as it is disclosed in the European patent application No. 09155216.6 with the title "Bubble trap system for an infusion pump device", filed by the applicants on the same day as the present application.

[0036] The connection device may also comprise further functional elements, e.g. a septum, a degassing membrane, a pressure sensor, a pressure transfer membrane, a pump chamber and/or a pumping mechanism, complete or in part. The connection device may also be realized as an integral part of a flexible container, permanently mounted on said flexible container, or as an integral part of an infusion pump device.

[0037] In an advantageous embodiment of a flexible container comprising a connection device, said connection device comprises elements for positioning and/or fixing the flexible container, for example positioning bolts, preferably interacting with elements for positioning and/or fixing of the flexible container.

[0038] A preferred embodiment of a flexible container according to the invention comprises an insert part according to the invention, as they will be described further below.

[0039] In addition a flexible container according to the invention may be provided with one or more additional ports mounted to the container wall, in addition to the access area. These additional ports may be used for transferring liquid to and from the storage compartment of the container, or may be used to deaerate the container if needed. Particularly a container according to the invention may comprise one or more ports as disclosed in European Patent Application No. 08167548 of the applicants, which is hereby incorporated by reference as part of this disclosure in its entirety. A flexible container according to the invention can also have the structural elements of a flexible container as disclosed in said application.

[0040] Furthermore a flexible container according to the invention may comprise additional preformed drain channels, formed by the two wall sheets. European Patent Application No. 08170627 of the applicants discloses a number of possible variants of such drain channels. The access area and the storage compartment of the container may for example be connected by one or more such additional drain channels. The content of said application is hereby incorporated by reference as part of
this disclosure in its entirety.

0041 Since essentially all elements necessary for fluidly connecting the flexible container to an infusion pump device are arranged inside the container, and no bulky external port is required, the overall volume of a container according to the invention and thus of an infusion pump device with such a container is considerably reduced. At the same time the dead volume is kept at a minimum.

0042 Typically a flexible container according to the invention will be provided hermetically closed and sealed, to keep the inside of the container sterile. The container will either be completely or partially filled with a liquid medicament, or will be empty.

0043 An insert part according to the invention for use in a flexible container according to the invention comprises an essentially flat body with a first, upper surface and a second, lower surface, and an inner conduit opening toward the upper surface. The inner conduit is fluidly connected to one or more drain channels and/or a drain channel network that lead to an outer edge of the insert part body.

0044 In an advantageous embodiment of an insert part according to the invention, the one or more drain channels are embodied as depressions arranged on the lower surface, and/or as tubular conduits arranged inside the body of the insert part.

0045 In another advantageous embodiment of an insert part according to the invention, one or more positioning elements are provided that are adapted to positively lock the insert part in the flexible container.

0046 In yet another advantageous embodiment of an insert part according to the invention, a sealing lip is arranged on the upper surface, for sealingly connecting the inner with an external conduit system. The sealing lip preferably consists of a material with higher elasticity than the material of the body of the insert part. Alternatively the sealing lip may consist of the same material as the body of the insert part. In any case the elasticity of the sealing lip should be higher that the elasticity of the counterpart of the connection device interacting with the sealing lip.

0047 In a further advantageous embodiment of an insert part according to the invention, the insert part comprises a secondary sealing lip arranged on the upper surface, for sealingly connecting the upper surface with an adjacent wall sheet of the flexible container.

0048 An insert part according to the invention may also comprise a septum, arranged in the inner conduit.

0049 When mounted in a flexible container, the essentially flat upper surface of the insert part according to the invention lies adjacent to the wall sheet. The inner conduit, leading to the flat upper surface of the insert part, opens to the access opening in the wall sheet.

0050 The insert part is arranged within a flexible container according to the invention with positive locking, and thus does not have to be mechanically attached to the wall sheets. Thus such a container can consist of only three parts, of which only two, namely the wall sheets, have to be sealingly connected, along a peripheral sealing rim. When one single, folded sheet is used instead of two separate wall sheets, even only two parts are sufficient for a container according to the invention. This uncomplex design of a flexible container according to the invention simplifies the assembly of the container, and consequently reduces manufacturing costs. Furthermore, since the insert part does not have to be directly attached to the wall sheets of the container, it is not necessary to choose materials for the insert part and the adjacent layer of the wall that are compatible for being sealed together, which provides more flexibility for the manufacturer when selecting the most appropriate materials for a certain purpose.

0051 A flexible container according to the invention has to be connected with an infusion pump device by a suitable connection device. Said connection device interacts with a specific access area of the container, in which the insert part is arranged. Sealing elements of the connection device and/or the insert part provide a liquid-tight connection between a conduit system of the connection device and the access opening of the container.

0052 After a liquid-tight sealing has been established, the storage compartment of the container is finally fluidly connected to the conduit system of the connection device, via the drain channel network and the inner conduit of the insert part. The infusion pump device can now draw the liquid medicament from the container. When the pump device of an infusion pump, arranged downstream of the conduit system of the connection device, sucks liquid, the liquid medicament in the container flows from the storage compartment through the drain channel network and the inner conduit of the insert part to the access opening, and then via the conduit system to the pump device. The container, fully or partially filled in the beginning, will continuously collapse, until finally the two wall sheets abut to each other. It is also possible to fill or refill the flexible container via the connection device.

0053 An advantageous device for the automated release of a liquid medicament, particularly an infusion pump device, comprises, incorporates or is capable of using a flexible container according to the invention.

0054 As used herein, the terms "medicament" and "liquid medicament" are meant to encompass any drug-containing flowable medicine, or therapeutic or diagnostic liquid, capable of being passed through a delivery element such as a hollow needle in a controlled manner, such as a liquid, solution, gel or fine suspension. Representative drugs include pharmaceuticals such as peptides, proteins, and hormones, biologically derived or active agents, hormonal and gene based agents, nutritional formulas and other substances in both solid (dispensed) or liquid form. In particular the term medicament encompasses insulin preparations ready for administration.

0055 The terms "subcutaneous infusion" and "subcutaneous injection" are meant to encompass any method in which a needle device is inserted at a selected site within the body of a patient for subcutaneous, intrave-
nous, intramuscular or intradermal delivery of a liquid medicament to a subject. Further, the term needle defines a piercing member (including an array of micro needles) adapted to be introduced into or through the skin of a subject.

The terms "drain channel" and "drain channel network" are meant to encompass any arrangement of depressions and protrusions on a surface that provide sufficient interconnected space between the surface and a flexible sheet firmly abutted to said surface that a fluid can flow through said space.

Brief description of the drawings

In order to facilitate a fuller understanding of the present invention, reference is now made to the appended drawings. These references should not be construed as limiting the present invention, but are intended to be exemplary only.

Figure 1 schematically shows an embodiment of a flexible container according to the invention (a) in a perspective view, and (b) in an explosion view.

Figure 2 schematically shows the insert part according to the invention as shown in Figure 1, (a) with view onto the lower and upper surface, and in a side view, and (b) in a perspective view onto the lower and upper surface.

Figure 3 schematically shows a flexible container according to the invention, interacting with a possible embodiment of a connection device, in a cross-section through the connection device, perpendicular to the longitudinal axis of the container.

Figure 4 schematically shows another embodiment of an insert part according to the invention, with the container completely drained, (b) with the container filled, and (c), (d) in a perspective view onto the lower surface.

Figure 5 schematically shows four different variants for drain channel arrangements of insert parts according to the invention, (a), (b) in a perspective view onto the lower surface, and (c), (d) with view onto the lower surface.

Figure 7 schematically shows another variant of a flexible container according to the invention, with a tubular element as an insert part, (a) in a cross-section perpendicular to the axis of the tubular element, (b) in a cross-section along the axis of the tubular element, and (c) in a top view.

Figure 8 schematically shows an embodiment of an insert part according to the invention with a needle stop, (a) in a side view, (b) in a cross-section through plane A--A, (c) in a top view, and (d) in a cross-section through plane B--B.

Figure 9 schematically shows a flexible container according to the invention, interacting with a possible embodiment of a connection device, with an insert part comprising a needle stop, in a cross-section through the connection device, perpendicular to the longitudinal axis of the container.

Figure 10 schematically shows in a top view two embodiments of a flexible container according to the invention, wherein the container comprises one single compartment.

Figure 11 schematically shows a flexible container according to the invention, with an insert part as shown in Figure 11, (a) with the flexible container completely drained, (b) with the container filled, and (c), (d) in a cross-section through the connection device, perpendicular to the longitudinal axis of the container.

Figure 12 schematically shows a flexible container according to the invention, comprising a sealing lip, (a) in a side view, (b) in a cross-section through plane D--D, (c) in a top view, and (d) in a perspective view.

Figure 13 schematically shows an embodiment of an insert part according to the invention, comprising a primary and a secondary sealing lip, (a) in a side view, (b) in a cross-section through plane D--D, (c) in a top view, and (d) in a perspective view.

Figure 14 schematically shows a flexible container according to the invention with an insert part as disclosed in Figure 13, interacting with a possible embodiment of a connection device, in a cross-section through the connection device, perpendicular to the lon-
to the invention has a flat, drop-like shape with a central circular body part and a tongue part. The rim of the insert part is beveled, in order to minimize the dead volume between the sealing rim 13 and the insert part 2, and to avoid mechanical stress on the preferably thin wall sheets. The insert part has an essentially flat upper surface 211, and lower surface 212. A single drain channel 22 is arranged on the lower surface 212 of the insert part, connected to the upper surface 211 by an inner conduit 23, realized as a bore arranged in the center of the insert part. The drain channel 22 is realized as an oblong depression on the lower surface 212, leading from the central inner conduit 23 to the end of the tongue part, opening to the storage compartment. The volume of the drain channel 22 and the inner conduit 23 is much smaller than the total volume of the container, and thus its contribution to the dead volume of the container is negligible.

The sealing of the two wall sheets 101, 102 may be achieved by heat sealing, ultrasonic welding, high-frequency inductive welding, gluing, or any other suitable method for producing flexible containers from sheet-like material that is known to the skilled person. The sheet-like material may be a single foil of a suitable polymer, or a compound foil. The base area of a flexible container according to the invention may have any suitable shape, particularly square, rectangular, circular, oval, hexagonal shape. The shape may also be specially adapted to a specific infusion pump device. Instead of sealing together two separate sheets, the wall of the container may also be produced from a single sheet that is folded along an axis, and is sealed along the remaining edges. Another possibility known from the state of the art is the use of continuous film tubes for producing the containers.

The material of the wall sheets can be a monolayer film or a multilayer structure. Preferably the wall sheets consist of one or more polymers of the following families: Polypropylene (PP), Polyethylene (PE), and co-polymers: Ethylene Vinyl Acetate (EVA), Polyvinyl Chloride (PVC), Polyvinylidene Chloride (PVDC), Polystyrene (PS), Ethylene Vinyl Alcohol (EVOH), Polyethylene Terephthalate (PET), Polyamide (PA), Polychlorotrifluoroethylene (PCTFE), Cyclic Olefin Copolymer (COC), Thermoplastic Elastomer (TPE), or generally any other polymer material which is known to the skilled person to be suitable for that purpose. The wall sheets may be manufactured for example by extrusion, blown film extrusion, coextrusion or lamination. When producing a multilayer structure it may be necessary to include one or more tie layers, or to apply one or more adhesive layers between the functional layers. To improve barrier properties one may also use metalized film, or a silicon oxide or aluminum oxide coating may be applied.

The insert part may consist of any suitable rigid or semi-rigid material, including glass, ceramics, metal, or suitable polymers. Preferably the insert part may consist of a polymer of the following families: Polypropylene (PP), Polyethylene (PE), and copolymers; Ethylene Vinyl Acetate (EVA), Polyvinyl Chloride (PVC), silicone or gen-
eraly any other polymer material which is known to the skilled person to be suitable for that purpose. If the insert part comprises a protruding sealing lip, preferable materials for the insert part are thermoplastic elastomers, elastomers, and silicone, or any other suitable material that is comparably soft and elastic. The same applies to the sealing lip if it is made from another material than the body of the insert part. The insert part may be manufactured by any suitable method, depending on the material used. If polymers are used, injection molding is the most preferable manufacturing method.

Since there is no material bonding between the insert part and the wall sheets of the container, it is not necessary to choose compatible materials for the insert part and the adjacent layer of the wall, which provides more flexibility for the manufacturer when selecting the most appropriate materials.

The shape of the insert part as shown in Figures 1 and 2 has the advantage that the insert part may be readily produced by injection molding, since there are no undercuts. The drain channels in the form of the oblong depression ensure a continuing fluid connection between the access opening and the storage compartment, even when the container is completely drained. Even under the external force of a clamp element of a connection device or due to the pressure difference between the inside and the outside of the container, the tubular connection formed by the drain channel 22 and the adjacent wall sheet 102 will not collapse.

Alternatively, the drain channel could be arranged on the upper surface of the insert part, in which case no inner conduit would be necessary. However, such an embodiment would be detrimental to the sealing effect between the insert part and the wall sheet in the annular area around the access opening, since the relevant area would not be completely flat.

In the embodiment of the flexible container depicted in Figure 1, the wall sheets are essentially flat. Consequently, also the insert part must be as flat as possible, in order to avoid folding of the wall sheets. In an alternative embodiment, one or both wall sheets may be provided with a hollow, in which the insert part can be arranged. Such an embodiment has the advantage that more voluminous inserts can be used, which may for example contain additional features, such as a septum, or a bubble trap.

As an alternative to a completely flat surface of the insert part, the upper surface facing the connection device may also be convex, if the shape of the sealing and pressure elements of a connection device are adapted to that specific shape.

In another advantageous embodiment of the invention, the drain channel network of the surface of the insert part is extended to the wall sheets of the flexible container. This can be achieved for example by hot embossing a grid of lines on at least a part of the inner surface of one or both wall sheets. In such an embodiment, the drain channel network of the insert part is connected to the embossed grid line network. No portion of the content of the container can be blocked and separated from the insert part when the container collapses in a sub-optimal manner during emptying, even for very large containers or very flexible container wall sheets, since the liquid can always flow to the insert part through the grid line network.

The possible geometrical form of a flexible container according to the invention is not restricted to the essentially rectangular form as shown in Figure 1, although a rectangular form is efficient and thus advantageous. The form of the flexible container may be adapted to any specific need, particularly to the dimensions of a certain pump device. The same holds true for the form, position and dimensions of the storage compartment.

The technical interaction between a flexible container according to the invention and an infusion pump device is depicted in more detail in Figure 3, which shows a flexible container 1 according to the invention, interacting with a connection device 3 of an infusion pump device (not shown), in a cross-section through the connection device 3 and the inner conduit of the insert part, perpendicular to the longitudinal axis 15 of the container.

The shown connection device 3 comprises a lower clamp part 31 and an upper clamp part 32, made from a stable, rigid material, such as metal or suitable polymer. An access area of the flexible container according to the invention, with the insert part 2, is clamped between the two clamp parts 31, 32, the upper surface 21 of the insert part facing toward the upper clamp part 32. The upper clamp part 32 comprises a conduit system 33, connected to an infusion pump device (not shown), in which a septum 331 is arranged. The conduit system 33 is aligned with the access opening 121 and the inner conduit 23 of the insert part 2.

A sealing element 34 in the form of an O-ring is arranged on the upper clamp part 32, facing toward the insert part 2 and pressed against the wall sheet 101. The O-Ring 34 thus provides a circumferential sealing between the conduit system 33 of the connection device 3 and the access opening 121 of the flexible container.

After the necessary sealing has been established, the storage compartment 11 of the container is now fluidly connected to the conduit system 33 of the connection device, via the drain channel 22, the inner conduit 23, and the access opening 121. The conduit system 33 may be connected to an infusion pump device (not shown), via a separate conduit opening to the conduit system 33 or via a hollow needle arranged in the septum 331.

The septum 331 provided in the shown embodiment of a connection device, for example made from silicone polymer, is only an optional feature. Through septum 331 a user may access the conduit system 33 and/or the container 1 with a syringe by penetrating the septum with a hollow needle. He may for example fill or refill the container with a liquid medicament, originating from a larger container, or he may clean the conduit system or deaerate the system.
After inserting the appropriate end 12 of the flexible container 1 between the two clamp parts 31, 32 of the connection device, the two clamp parts 31, 32 are locked together. A skilled person will know a number of different methods for friction-locking or form-locking said two parts. For example, one clamp part may be equipped with snap bolts, which are inserted into corresponding holes of the other clamp part. Said snap bolts could at the same time be used for positioning and/or fixing the container, for example if the container comprises corresponding holes in a sealed area of the wall sheets (see for example the embodiment of a container according to the invention disclosed in Figure 7(c)). In an advantageous embodiment the snap bolts are inserted into the holes of the container, thereby fixing its position in a definite way in relation to the clamp parts. European Patent Application 08170627 of the applicant discloses such a clamp locking system, which can also be applied for flexible containers according to this invention.

The connection device 3 may comprise further functional elements, such as for example a bubble trap, a pressure sensor, or a pressure transfer membrane for coupling a conduit system 33 of the connection device to a pressure sensor. Furthermore it may comprise a pumping/dosing mechanism, or part of a pumping mechanism, such as a micro membrane pump, or a micro plunger pump.

A connection device according to the invention may be embodied as a separate unit, as shown in Figure 2, or may be permanently attached to the flexible container, or may be directly attached to an infusion pump device. For example may the lower clamp part 51 be an integral part of a ground plate of an infusion pump device. The flexible container itself may be easily removed from the infusion pump device, or may be an integral part of the device. In the former case a user, particularly a patient using the device, may replace an emptied container with a new, prefilled single-use container, or he may remove the container for refilling. Replaceable single-use containers are highly preferred for quality assurance reasons. In the latter case the container is directly refilled in the device, for example by a septum in the connection device or by an additional port mounted on the container. If the container has to be replaced for maintenance reasons, this may be done by the user himself, or by a maintenance service.

The insert part 2 of the flexible container disclosed in Figures 1 and 2 is designed to be positioned within the container 1 in one single, clearly defined orientation. Alternatively, however, it is possible to realize the insert part in a way that allows multiple orientations.

Such an embodiment of an insert part 2 is depicted in Figure 4. Said insert part 2 has an essentially disc shaped form, with an inner conduit 23 arranged in the center of the disc. On one surface of the disc six drain channels 22 are symmetrically arranged, radiating from the inner conduit 23 towards the peripheral rim, and forming a drain channel network 221.

Rotation symmetric insert parts as shown in Figure 4 have the advantage that only the orientation of the two surfaces 211, 212 has to be correct. It is, however, irrelevant how the insert part is rotationally oriented along its central axis. If the neck 16 of the flexible container is chosen sufficiently wide, in every orientation angle at least one drain channel 22 will open to the storage compartment, providing a fluid connection 22, 23 between the access opening 121 and the storage compartment 11. This irrelevancy of the orientation angle significantly simplifies the assembly process of a flexible container with an insert part.

Yet another embodiment of an insert part 2 for use in a flexible container 1 according to the invention is shown in Figure 5, where eight tubular drain channels 22 are radially arranged inside the body 21 of the insert part 2. The assembly of a flexible container with such an insert part 2 is even simpler that with the insert part of Figure 4, since both surfaces 211, 212 are equivalent. Figure 5(d) depicts the access area of a flexible container 1 according to the invention, in which such an insert part is arranged with positive locking.

An additional advantage of an insert part 2 as shown in Figure 5 is that also a possible dead volume in the peripheral zone between the sealing rim 13 and the edge of the insert part is accessible through the drain channels 22 facing toward the sealing rim 13. Furthermore there may be a circumferential channel around the flexible container between the two wall sheets close to the sealing rim 13, due to a certain stiffness of the wall sheets close to the sealing rim. It is thus possible to empty also said peripheral zone and circumferential channel, thereby further reducing the dead volume.

Other examples of possible arrangements of drain channels 22 of embodiments of insert parts 2 are given in Figure 6. Figure 6(a) shows another embodiment of an insert part 2, with three drain channels 22 arranged in a star-like manner on the lower surface 212 of the insert part 2. In the variant in Figure 6(b) a number of protrusions 222 is arranged on the lower surface 212 of the insert part 2, the protrusions between said protrusions forming a network 221 of drain channels 22. In the embodiment in Figure 6(c) three linear and two circular drain channels 22 are arranged on the surface 212, while in Figure 6(d) the drain channels 22 form a grid-like network 221.

Generally the drain channels should be as shallow as possible, in order to decrease the dead volume. Among other factors, the achievable minimum depth of the drain channels 22 of a given channel network 221 in order to avoid blocking of the channels depends on the flexibility of the material of the wall sheet 102 and the width of the channels 22. Furthermore a given minimum flow must be ensured, which depends for example on the demands of the dosing pump and the viscosity of the liquid medicament.

Another advantageous variant of a flexible container 1 according to the invention is shown in Figure 7. In this particular embodiment the insert part 2 is realized...
as a tubular element arranged in the access area 12 of the flexible container 1, parallel to the longitudinal axis 15. The access opening 121 is arranged on top of the tubular insert part 2. One open end of the tubular insert part 2 opens to the storage compartment 11, while the other end is blocked by the sealing rim 13. The drain channel 22 and inner conduit 23 of the tubular insert part are both provided by the inner space of the tubular element. The sealing element and pressure element of a connection device have to be adapted to the specific form of the surface of the wall sheet around the access opening 121.

An advantage of such an embodiment of a flexible container is that a very simple insert part may be used, which may even be provided continuously during manufacture, for example feed from a bobbin. In an alternative version the tubular insert part may even protrude into the storage volume compartment of the container. In another variant the tubular insert part may be bent to a half circle, with both ends facing toward the storage compartment. The access opening would then be positioned in the middle of the tubular element 2.

In the embodiment of the flexible container 1 disclosed in Figure 7(c), the sealing rim 13 is broadened in the access area 12, and forms a sealed area 14. In said area 14 four holes are arranged, which act as positioning elements 17 for precisely positioning the flexible container 1 within a connection device. For example the connection device may comprise positioning bolts that interact with the positioning holes 17. In another possible variant the positioning elements are grooves or protrusions in the sealed area 14 that interact with protrusions and/or grooves arranged on the clamp parts. The use of positioning elements is also favorable in the context of all other embodiments of flexible containers according to the invention, with other types of insert parts. In an even more advantageous variant, as it is realized in Figure 7(c), the positioning elements 17 are arranged asymmetrically. This will allow only one possible way to connect the container 1 with a connection device, which reduces the risk of wrong manipulations by a user.

When puncturing the access opening of a flexible container according to the invention, care must be taken that not accidentally both wall sheets are punctured, which would compromise the sealing of the connection between the container and the connection device. This can be achieved by an optional needle stop 24 arranged in the insert part 2, as shown in Figures 8 and 9.

In the insert parts 2 shown in Figures 8 and 9, the inner conduit 23 is realized as a blind hole, the remaining rigid wall of the surface 212 opposite to the connection device 3 acting as a needle stop 24. When a needle 332 is pushed through the septum 331 and the upper wall sheet 101, the needle stop 24 prevents the point of the needle 332 from reaching the other wall sheet 102. A needle stop 24 as shown in Figures 8 and 9 may not only be used in an insert part with tubular drain channels 22, but also with drain channels realized as oblong depressions as given for example in Figures 1 to 4.

In the embodiments of flexible containers discussed so far the insert part is immobilized within the container by positively locking it within a compartment divided from the storage compartment by a neck or constriction. However, a flexible container according to the invention may also comprise only one single compartment, acting both as the storage compartment and as the access area. Two possible examples of such flexible containers according to the invention are shown in Figure 10.

In the embodiment shown in Figure 10(a) the inner compartment comprises a bulge 12 at its periphery, in which the body 21 of the insert part 2 is arranged. Since the bulge 12 is not undercut, the previously discussed insert parts 2 would not be positively locked within the access area 12 formed by the bulge 12. For that purpose the insert part 2 in Figure 10(a) comprises a hoop-like positioning element 25, which is located inside the storage compartment 11 along the sealing rim 13, thereby positively locking the insert part 2 within the container 1. In addition the disclosed insert part 2 comprises optional two distance elements 26, protruding into the storage compartment 11. When the flexible container 1 is nearly completely drained, the distance elements 26 will prevent a constriction of a part of the storage compartment 11. On the other hand, if the container is provided initially empty, the distance elements 26 will prevent the wall sheets 101, 102 from sticking together.

Figure 10(b) depicts a flexible container according to the invention, in which the insert part 2 is arranged in the center of a rectangularly shaped storage compartment 11. Again the insert part 2 is kept in position by a hoop-like positioning element 25, which is attached to the insert part 2 by four radial distance elements 26. In this variant the access area 12 is located in the center of the storage compartment 11.

A further advantageous variant of an insert part 2 for use with a flexible container 1 according to the invention is shown in Figures 11 and 12. In the depicted insert part 2, which has four oblong depressions as drain channels 22, a circular sealing lip 27 is arranged around the access opening 121. The sealing lip 27 protrudes from the essentially flat surface 211 of the insert part 2.

In a flexible container with such an insert part, the access opening 121 on the upper wall sheet 101 comprises a larger circular hole 103, through which the sealing lip 27 protrudes. The sealing lip 27 is designed to interact with the sealing element 34 of a connection device 3, thereby providing a liquid-tight sealing between the conduit system 33 of the connection device and the inner conduit 23 of the insert part. A liquid-tight sealing between the wall sheet 101 and the insert part 2 is the result of the external pressure of a pressure element 35 of the connection device 3, acting on an annular area around the access opening 121 and the sealing lip 24.

To ensure sterility, the access opening or even
the whole access area may initially be covered by a removable cap or coverage. In a preferred embodiment of a flexible container, with a readily attached connection device, such removable caps or covers will typically be provided on the fluid connectors of the connection device.

0096 An advantage of such an embodiment of an insert part and a flexible container is the fact that the liquid medicament inside the container will only get into contact with the inner surface of the wall sheets. This may be especially advantageous if the wall sheet has a multiple layer structure, and a contact between the liquid medicament and one of the outer layers should be avoided.

0097 The use of a flexible container 1 according to the invention with an insert part 2 as shown in Figure 11 is explained in more detail in Figure 12. An initially empty container 1 is fastened in a connection device 3 (Figure 12(a)). Said connection device comprises a lower clamp part 31 with a recess, in which the access area 12 of the container is located, and an upper clamp part 32. The upper clamp part 32 comprises a pressure element 35 in the form of a circular lip, pressing together the surface 211 of the insert part 2 and the upper wall sheet 101. The sealing lip 27 is in close contact with the surface of the upper clamp part 32, providing a fluid connection between the inner conduit 23 and the conduit system 33. In the shown embodiment the upper clamp part 32 does not comprise a special sealing element, but a flat contact zone 34. This is for example possible if the polymer material of the insert part 2 and/or the clamp part itself shows a certain elasticity. If the combined elasticity of sealing lip 27 and sealing element 34 is not sufficient, a sealing ring may be arranged on the clamp part 32.

0098 After the container 1 has been fluidly connected with the connection device 3, it is filled with its liquid content using a syringe with hollow needle, through the septum 331. When the container 1 is completely filled, the hollow needle is retracted and the system comprising the container 1 and the connection device 3 are ready for use (Figure 12(b)). A pump device (not shown) may now suck liquid from the container 1 through the conduit system 33, 33'. The septum 331 may also be used to deaerate the conduit system.

0099 A further variant of an insert part 2 similar to Figure 11 is given in Figure 13 and 14. In said embodiment the upper surface 211 of the insert part 2 comprises a secondary, outer sealing lip 28, arranged in the periphery of the first, central sealing lip 27. When interacting with a flatly surfaced pressure element 35 of a connection device 3 (Figure 14), the secondary sealing lip 28 increases the local pressure between the upper surface 211 of the insert part 2 and the adjacent wall sheet 101, improving the sealing between insert part 2 and wall sheet 101.

0100 Figure 15 discloses an embodiment of an insert part 2 with a sealing 27, manufactured by two-component injection molding. While the body 21 of the insert part 2 consists of a rigid material, the sealing lip 27 is made from a comparably soft, elastomeric material. When locked in a connection device 3 (Figure 16), the resilient elastomeric sealing lip 27 establishes the liquid-tight connection of the access opening 121 with the conduit system 33 of the upper clamp part 32.

0101 In all embodiments of flexible containers according to the invention discussed so far, the insert part 2 and the adjacent wall sheet 101 were not bounded to each other.

0102 When a liquid-tight sealing between insert part 2 and wall sheet 101 is necessary, as for example in the embodiments shown in Figures 11, 12, 13, and 14, said sealing is provided solely by the temporarily exerted external pressure force 35 acting on the two elements 211, 101. Alternatively, in all disclosed embodiments the insert part may be permanently connected to the wall sheet, by heat sealing, ultrasonic welding, high-frequency inductive welding, gluing, or any other suitable method. On one hand, this variant of the invention needs an additional step during manufacture, but on the other hand there is no need for a pressure element on the clamp part of a connection element 3.

0103 An example of a flexible container 1 according to the invention with permanently sealed wall sheet 101 and insert part 2 is shown in Figure 17. The disclosed insert part 2 is similar to the one shown in Figure 14. However, since the surface 211 of the insert part 2 is sealed to the wall sheet 101, there is no need for an additional pressure element of the connection element.

0104 The present invention is not to be limited in scope by the specific embodiments described herein. Indeed, various modifications of the present invention, in addition to those described herein, will be apparent to those skilled in the art from the foregoing description and accompanying drawings. Thus, such modifications are intended to fall within the scope of the appended claims. Additionally, various references are cited throughout the specification, the disclosures of which are each incorporated herein by reference in their entirety.

Claims

1. A flexible container (1) for storing a liquid medicament, with a container wall consisting of two wall sheets (101, 102) of flexible material that are sealed together (13, 14), the container (1) comprising a storage compartment (11) for the liquid medicament, and an access opening (121) on one of the wall sheets (101), wherein the storage compartment (11) and the access opening (121) are in fluid connection, and the access opening (121) is designed to be fluidly connected to an outer conduit system (33), characterized by an insert part (2) that is arranged between the two wall sheets (101, 102) with positive locking, and that fluidly connects (22, 23, 221) the storage compartment (11) and the access opening (121).

2. The flexible container according to claim 1, characterized in that the insert part (2) is arranged and positively locked in an access area (12) of the container (1), which is separated from the storage compartment (11) by a neck (15) or constriction.

3. The flexible container according to claim 1 or 2, characterized by elements for positioning and/or fixating (17) the flexible container (1) in a connection device (3), particularly in a connection device (5) of an infusion pump device (2).

4. The flexible container according to claim 3, characterized in that the elements for positioning and/or fixing are two or more holes (17) and/or grooves arranged in a sealed area (14) of the container, and/or in an area of the wall sheets (101, 102) outside of the sealed area that does not belong to the storage compartment (11).

5. The flexible container according to any of the preceding claims, characterized in that the access opening (121) comprises a hole (103) arranged in a wall sheet (101) adjacent to the insert part (2), and the insert part (2) comprises a sealing lip (27) arranged on the upper surface (211) of the insert part, wherein the sealing lip (27) protrudes through the hole (103) of the access opening (121).

6. The flexible container according to claim 5, characterized in that the positive locking of the insert part (2) in the flexible container (1) is at least partially achieved by the sealing lip (27) protruding through the hole (103) of the access opening (121).

7. The flexible container according to any of the preceding claims, characterized by a connection device (3) for use in an infusion pump device, comprising two clamp parts (31, 32) that are adapted to positively and/or non-positively locking the flexible container (1), and to fluidly connecting an access opening (121) of the flexible container (1) to a conduit system (33) of the connection device (3).

8. The flexible container according to claim 7, characterized in that the clamp part (32) facing toward the access opening (121) comprises a sealing element (34) that is adapted to fluidly connecting the conduit system (33) with the access opening (121) of the flexible container (1).

9. The flexible container according to any of claims 7 or 8, characterized in that the surface of the clamp parts (31, 32) of the connection device (3) is adapted to the exterior shape of the flexible container (1), particularly to the exterior shape of an access area (12) of the container (1).

10. The flexible container according to any of claims 7 to 9, characterized in that the connection device (3) comprises elements for positioning and/or fixating the flexible container (1), preferably interacting with elements for positioning and/or fixating (17) of the flexible container (1).

11. The flexible container according to any of the preceding claims, characterized by an insert part (2) according to any of claims 12 to 16.

12. An insert part (2) for use in a flexible container (1) according to any of claims 1 to 11, the insert part (2) comprising an essentially flat body (21) with a first, upper surface (211) and a second, lower surface (212), and an inner conduit (23) opening toward the upper surface (211), and being fluidly connected to one or more drain channels (22, 221) that lead to an outer edge of the body (21).

13. The insert part according to claim 12, characterized in that the one or more drain channels (22, 221) are...
embodied as depressions arranged on the lower surface (212), and/or as tubular conduits arranged inside the body (21) of the insert part (2).

14. The insert part according to claim 12 or 13, characterized by one or more positioning elements (25), adapted to positively locking the insert part (2) in the flexible container (1).

15. The insert part according to any of claims 12 to 14, characterized by a sealing lip (27) arranged on the upper surface (211), for sealingly connecting the inner conduit (23) with an external conduit system (33), the sealing lip (27) preferably consisting of a material with higher elasticity than the material of the body (21) of the insert part.

16. The insert part according to any of claims 12 to 15, characterized by a secondary sealing lip (28) arranged on the upper surface (211), for sealingly connecting the upper surface (211) with an adjacent wall sheet (101) of the flexible container (1).

17. A device for the automated release of a liquid medicament, particularly an infusion pump device, comprising, incorporating, and/or capable of using at least one flexible container according to any of claims 1 to 11.

- The present search report has been drawn up for all claims

Examiner:

Ceccarelli, David

Date of completion of the search: 22 September 2009

Munich
## CLAIMS INCURRING FEES

The present European patent application comprised at the time of filing claims for which payment was due.

- [ ] Only part of the claims have been paid within the prescribed time limit. The present European search report has been drawn up for those claims for which no payment was due and for those claims for which claims fees have been paid, namely claim(s):

- [ ] No claims fees have been paid within the prescribed time limit. The present European search report has been drawn up for those claims for which no payment was due.

## LACK OF UNITY OF INVENTION

The Search Division considers that the present European patent application does not comply with the requirements of unity of invention and relates to several inventions or groups of inventions, namely:

> see sheet B

- [ ] All further search fees have been paid within the fixed time limit. The present European search report has been drawn up for all claims.

- [ ] As all searchable claims could be searched without effort justifying an additional fee, the Search Division did not invite payment of any additional fee.

- [ ] Only part of the further search fees have been paid within the fixed time limit. The present European search report has been drawn up for those parts of the European patent application which relate to the inventions in respect of which search fees have been paid, namely claims:

  1-11, 17

- [ ] The present supplementary European search report has been drawn up for those parts of the European patent application which relate to the invention first mentioned in the claims (Rule 164 (1) EPC).
The Search Division considers that the present European patent application does not comply with the requirements of unity of invention and relates to several inventions or groups of inventions, namely:

1. claims: 1-11, 17

   Flexible container with a container wall consisting of two sheets, a storage compartment, an access opening and an insert part fluidly connecting the storage compartment and the access opening.

   ---

2. claims: 12-16

   Insert part with a flat body, an upper and lower surface and an inner conduit fluidly connected to drain channels.

   ---
This annex lists the patent family members relating to the patent documents cited in the above-mentioned European search report. The members are as contained in the European Patent Office EDP file on The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
