Note: Within nine months of the publication of the mention of the grant of the European patent in the European Patent Bulletin, any person may give notice to the European Patent Office of opposition to that patent, in accordance with the Implementing Regulations. Notice of opposition shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

[0001] This invention is related to the field of integrated circuits and, more particularly, to command processing in a peripheral component in an integrated circuit.

Description of the Related Art

[0002] In a peripheral interface controller that has significant data bandwidth, one of the challenges that can occur is providing the control input to the peripheral interface controller from an external processor. Typically, the same internal interface to the peripheral controller that transfers data between the peripheral interface controller and memory is used to provide the control input from the external processor (e.g., via a series of writes to control registers in the peripheral interface controller). While the data transfers are occurring, the memory to peripheral interface can be saturated with the data transfers. Accordingly, control inputs to arrange for the next set of data transfers can be effectively locked out until the current data transfers complete. During the time that the control inputs are being provided, the external peripheral interface controlled by the peripheral interface controller can be idle.

[0003] One mechanism for reducing the contention on the peripheral to memory interface is to include a processor in the peripheral interface controller, executing a program to control the peripheral interface controller hardware. However, such a mechanism is expensive in a number of ways: in monetary terms to acquire the processor (either as a discrete component or as intellectual property that can be incorporated into the peripheral interface controller design); in terms of space occupied by the peripheral interface controller when the processor is included; and in terms of power consumed by the processor. Additionally, the program to be executed is stored in the system memory, and thus instruction fetches can compete with the data transfers on the peripheral to memory interface.

[0004] The document WO 2009/057955 discloses an apparatus for controlling NAND flash memory. The apparatus for controlling NAND flash memory includes: a register unit in which a start address of a macro-command to be executed, selected from macro-commands included in a command script in which at least one macro-command in which a plurality of micro-commands for controlling a unit operation of NAND flash memory are arranged in an array shape, is described, is recorded; a command fetch unit, if a start address of the macro-command to be executed is recorded in the register unit, accessing first memory connected based on the start address of the macro-command to be executed and sequentially reading the plurality of micro-commands from the start address of the macro-command to be executed; a command decoding unit decoding the read micro-commands and outputting the result of interpretation including types of the micro-commands and command parameters; and a command execution unit generating interface signals for controlling an operation of NAND flash memory according to each of the micro-commands based on the result of interpretation.

SUMMARY

[0005] In an embodiment, an integrated circuit includes a peripheral component configured to control an external interface of the integrated circuit. For example, the peripheral component may be a memory interface unit such as a flash memory interface unit. The internal interface to the peripheral component may be shared between data transfers to/from the external interface and control communications to the peripheral component. The peripheral component may include a command queue configured to store a set of commands to perform a transfer on the interface. A control circuit may be coupled to the command queue and may read the commands and communicate with an interface controller to cause a transfer on the interface responsive to the commands.

[0006] In an embodiment, the commands in the command queue may be downloaded to the command queue at times that data transfers are not occurring on the internal interface. The commands may be available in the command queue to perform the next transfer, for example, when the current transfer completes. The internal and external interfaces may be used efficiently, in some embodiments, even in the face of contention between data transfers and control transfers on the internal interface.

[0007] The invention is defined in the apparatus claim 1 and the corresponding method claim 10.

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] The following detailed description makes reference to the accompanying drawings, which are now briefly described.

[0009] Fig. 1 is a block diagram of one embodiment of an integrated circuit, a memory, and a flash memory.

[0010] Fig. 2 is a block diagram of one embodiment of a flash memory interface illustrated in Fig. 1.

[0011] Fig. 3 is a flowchart illustrating operation of one embodiment of a flash memory interface control circuit illustrated in Fig. 2 in response to receiving a write operation.

[0012] Fig. 4 is a table illustrating one embodiment of commands supported by the flash memory interface control circuit.

[0013] Fig. 5 is a flowchart illustrating operation of one embodiment of the flash memory interface control circuit shown in Fig. 2 in response to reading a command from the command first-in, first-out buffer (FIFO).

[0014] Fig. 6 is a block diagram of an example use of a macro memory.

[0015] Fig. 7 is a flowchart illustrating operation of one embodiment of flash memory interface code executed
by one embodiment of a processor shown in Fig. 1.

Fig. 8 is a block diagram of one embodiment of a system including the apparatus illustrated in Fig. 1.

Fig. 9 is a block diagram of one embodiment of a computer accessible storage medium.

While the invention is susceptible to various modifications and alternative forms, specific embodiments thereof are shown by way of example in the drawings and will herein be described in detail. It should be understood, however, that the drawings and detailed description thereto are not intended to limit the invention to the particular form disclosed, but on the contrary, the intention is to cover all modifications, equivalents and alternatives falling within the scope of the present invention as defined by the appended claims. The headings used herein are for organizational purposes only and are not meant to be used to limit the scope of the description. As used throughout this application, the word "may" is used in a permissive sense (i.e., meaning having the potential to), rather than the mandatory sense (i.e., meaning must). Similarly, the words "include", "including", and "includes" mean including, but not limited to.

Various units, circuits, or other components may be described as "configured to" perform a task or tasks. In such contexts, "configured to" is a broad recitation of structure generally meaning "having circuitry that" performs the task or tasks during operation. As such, the unit/circuit/component can be configured to perform the task even when the unit/circuit/component is not currently on. In general, the circuitry that forms the structure corresponding to "configured to" may include hardware circuits and/or memory storing program instructions executable to implement the operation. The memory can include volatile memory such as static or dynamic random access memory and/or nonvolatile memory such as optical or magnetic disk storage, flash memory, programmable read-only memories, etc. Similarly, various units/circuits/components may be described as performing a task or tasks, for convenience in the description. Such descriptions should be interpreted as including the phrase "configured to."

DETAILED DESCRIPTION OF EMBODIMENTS

Turning now to Fig. 1, a block diagram of one embodiment of an integrated circuit 10 coupled to an external memory 12 and one or more flash memory devices 28A-28B is shown. In the illustrated embodiment, the integrated circuit 10 includes a memory controller 14, a system interface unit (SIU) 16, a set of peripheral components such as components 18A-18B, a flash memory interface unit 30, a set of peripheral components such as components 18A-18B, a flash memory interface unit 30, a central DMA (CDMA) controller 20, a processor 22 including a level 1 (L1) cache 24, a level 2 (L2) cache 26, and an input/output (I/O) processor (IOP) 32. The memory controller 14 is coupled to a memory interface to which the memory 12 may be coupled, and is coupled to the SIU 16. The CDMA controller 20, the L2 cache 26, and the processor 22 (through the L2 cache 26) are also coupled to the SIU 16 in the illustrated embodiment. The L2 cache 26 is coupled to the processor 22, and the CDMA is coupled to the components 18A-18B, the flash memory interface unit 30, and the IOP 32. One or more peripheral components 18A-18B may be coupled to external interfaces as well, such as the peripheral component 18A. In other embodiments, other components may be coupled to the SIU 16 directly (e.g. other peripheral components).

The CDMA controller 20 may be configured to perform DMA operations between the memory 12, various peripheral components 18A-18B, and/or the flash memory interface unit 30. Various embodiments may include any number of peripheral components and/or flash memory interface units 30 coupled through the CDMA controller 20. The processor 22 (and more particularly, instructions executed by the processor 22) may program the CDMA controller 20 to perform DMA operations. Various embodiments may program the CDMA controller 20 in various ways. For example, DMA descriptors may be written to the memory 12, describing the DMA operations to be performed, and the CDMA controller 20 may include registers that are programmable to locate the DMA descriptors in the memory 12. Multiple descriptors may be created for a DMA channel, and the DMA operations described in the descriptors may be performed as specified. Alternatively, the CDMA controller 20 may include registers that are programmable to describe the DMA operations to be performed, and programming the CDMA controller 20 may include writing the registers.

Generally, a DMA operation may be a transfer of data from a source to a target that is performed by hardware separate from a processor that executes instructions. The hardware may be programmed using instructions executed by the processor, but the transfer itself is performed by the hardware independent of instruction execution in the processor. At least one of the source and target may be a memory. The memory may be the system memory (e.g. the memory 12), the flash memory devices 28A-28B, or may be an internal memory in the integrated circuit 10, in some embodiments. Some DMA operations may have memory as a source and a target (e.g. a DMA operation between the memory 12 and the flash memory devices 28A-28B, or a copy operation from one block of the memory 12 to another). Other DMA operations may have a peripheral component as a source or target. The peripheral component may be coupled to an external interface on which the DMA data is to be transferred or on which the DMA data is to be received. For example, the peripheral component 18A may be coupled to an interface onto which DMA data is to be transferred or on which the DMA data is to be received. Thus, a DMA operation may include the CDMA controller 20 reading data from the source and writing data to the destination. The data may flow through the CDMA controller 20 as part of the DMA operation. Particularly, DMA data for a DMA read from the memory 12 may flow through the memory controller 14, over the SIU 16,
through the CDMA controller 20, to the peripheral component 18A-18B or the flash memory interface unit 30 (and possibly on the interface to which the peripheral component is coupled, if applicable). Data for a DMA write to memory may flow in the opposite direction.

In one embodiment, instructions executed by the processor 22 and/or the IOP 32 may also communicate with the peripheral components 18A-18B and the flash memory interface unit 30 using read and/or write operations referred to as programmed input/output (PIO) operations. The PIO operations may have an address that is mapped by the integrated circuit 10 to a peripheral component 18A-18B or the flash memory interface unit 30 (and more particularly, to a register or other readable/writable resource in the component). The address mapping may be fixed in the address space, or may be programmable. Alternatively, the PIO operation may be transmitted in a fashion that is distinguishable from memory read/write operations (e.g. using a different command encoding than memory read/write operations on the SIU 16, using a sideband signal or control signal to indicate memory vs. PIO, etc.). The PIO transmission may still include the address, which may identify the peripheral component 18A-18B or the flash memory unit 30 (and the addressed resource) within a PIO address space, for such implementations.

In one embodiment, PIO operations may use the same interconnect as the CDMA controller 20, and may flow through the CDMA controller 20, for peripheral components 18A-18B and the flash memory interface unit 30. Thus, a PIO operation may be issued by the processor 22 onto the SIU 16 (through the L2 cache 26, in this embodiment), to the CDMA controller 20, and to the targeted peripheral component/flash memory interface unit. Similarly, the IOP 32 may issue PIO operations to the CDMA controller 20, which may transmit the PIO operation over the same interconnect to the peripheral components 18A-18B or the flash memory interface unit 30.

Accordingly, data transfers for a DMA operation to/from a peripheral component 18A-18B or the flash memory interface unit 30 may conflict with PIO operations to/from the same peripheral component 18A-18B or the flash memory interface unit 30. For example, the flash memory interface unit 30 may be programmed via PIO operations to perform memory transfers to/from the flash memory devices 28A-28B. For write operations, the CDMA controller 20 may DMA the data to be written to the flash memory interface unit 30. For read operations, the CDMA controller 20 may DMA the data to be read from the flash memory interface unit 30. In an embodiment, flash memory devices 28A-28D may support a page of data transfer to/from the devices. The size of the page is device-dependent, and may not be the same as the page size used for virtual-to-physical address translation for the memory 12. For example, page sizes of 512 bytes, 2048 bytes, and 4096 bytes are often used. Accordingly, a page may be the unit of transfer of data for the memory device, in this context.

In one embodiment, the flash memory interface unit 30 may be programmed to perform a page of data transfer, and the CDMA unit 20 may perform the DMA operations to transfer the data. If multiple pages are to be transferred, additional PIO operations may be used to program the flash memory interface unit 30 to perform the next transfer. However, the DMA operations may effectively lock out the additional PIO operations until the current page completes. Thus, the time elapsing while programming the flash memory interface unit 30 for the next page may result in idle time on the interface to the flash memory devices.

In one embodiment, the flash memory interface unit 30 may support a command queue. Commands to program the flash memory interface unit 30 for a set of pages to be transferred may be queued in the command queue. Once the DMA operations for the first page begin, the data to program the flash memory interface unit 30 and the DMA operations to transfer the data. The utilization on the interface to the flash memory devices 28A-28B may be increased due to the ability to process the commands from the command queue to configure the flash memory controller 30 for the next page to be transferred while the CDMA unit 30 completes the DMA operations for the current page.

In an embodiment, the flash memory interface unit 30 may support a macro memory to store one or more macros. A macro may be a sequence of two or more commands that may be invoked via a macro command. For example, the macro command may be written to the command queue, and may invoke the macro when the macro command is performed by the flash memory interface unit 30. Macros that implement frequently-used sequences of commands may be downloaded to the macro memory, and thus fewer commands need be downloaded subsequently. That is, macro commands may be written to the command queue instead of repeatedly writing the commands that are stored in the macro. In one embodiment, the macro command may specify a starting address of the macro and a number of words in the macro. Once the number of words have been read from the macro and the corresponding commands have been performed, the next command in the command queue after the macro command may be performed. Accordingly, return commands may be avoided in the macro, permitting more dense macros in an embodiment. Other embodiments may use the starting address and a number of commands as operands. Still other embodiments may implement a return command and the macro command may include the starting address (but not word/command count) as an operand. In an embodiment, the macro command may also include a loop count operand. The loop count operand may specify a number of iterations of the macro that are to be performed. Thus, per-
forming the macro command may include reading the number of words beginning at the starting address and performing the commands, iterated the loop count number of times, before proceeding with the next command in the command queue after the macro command.

[0029] Commands in the command queue and/or commands in the macro memory may use operands to control their operation. In some cases, the operands may be stored in the command queue. In other cases, the operands may be stored in an operand queue. Commands in the command queue or in the macro memory may specify that the flash memory interface unit 30 load operands from the operand queue and operate on the operands. The operand queue may be used with a macro to supply instance-specific data for the generic macro (e.g. flash memory addresses, chip enables, etc.). Similarly, the operand queue may supply operands for the commands in the command queue.

[0030] A memory transfer, as used herein, may refer to the transfer of data to/from a memory device (via the interface to the memory device). Thus, a memory transfer to/from the flash memory devices 28A-28B may occur over the interface between the flash memory devices 28A-28B and the flash memory interface unit 30. Similarly, a memory transfer to/from the memory 12 may occur over the interface between the memory 12 and the memory controller 14. The memory transfer may occur using a protocol defined by the memory devices. Additionally, a command may refer to one or more bytes of data that are interpreted by the hardware in the peripheral component (e.g. the flash memory interface unit 30) as specifying a particular operation to be performed by the hardware.

[0031] Generally, a peripheral component may be any desired circuitry to be included on the integrated circuit 10 with the processor. A peripheral component may have a defined functionality and interface by which other components of the integrated circuit 10 may communicate with the peripheral component. For example, peripheral components may include video components such as display controllers, graphics processors, etc.; audio components such as digital signal processors, mixers, etc.; networking components such as an Ethernet media access controller (MAC) or a wireless fidelity (WiFi) controller; controllers to communicate on various interfaces such as universal serial bus (USB), peripheral component interconnect (PCI) or its variants such as PCI express (PCIe), serial peripheral interface (SPI), flash memory interface, etc. The flash memory interface unit 30 may be one example of a peripheral component, and the general properties of a peripheral component described herein may be applicable to the flash memory interface unit 30.

[0032] The processor 22 may implement any instruction set architecture, and may be configured to execute instructions defined in that instruction set architecture. The processor 22 may employ any microarchitecture, including scalar, superscalar, pipelined, superpipelined, out of order, in order, speculative, non-speculative, etc., or combinations thereof. The processor 22 may include circuitry, and optionally may implement microcoding techniques. In the illustrated embodiment, the processor 22 may include an L1 cache 24 to store data and instructions for use by the processor 22. There may be separate L1 data and instruction caches. The L1 cache(s) may have any capacity and organization (set associative, direct mapped, etc.). In the illustrated embodiment, an L2 cache 26 is also provided. The L2 cache 26 may have any capacity and organization, similar to the L1 cache(s).

[0033] Similarly, the IOP 32 may implement any instruction set architecture, and may be configured to execute instructions defined in that instruction set architecture. The instruction set architecture implemented by the IOP 32 need not be the same instruction set architecture implemented by the processor 22. In one embodiment, the IOP 32 may be a lower power, lower performance processor than the processor 22. The IOP 32 may handle various I/O interface issues (configuring peripheral components to perform desired operations, certain error handling, etc.). The IOP 32 may execute instructions to write commands to the command queue in the flash memory interface unit 30, write macros to the macro memory in the flash memory interface unit 30, and/or write operands to the operand queue in the flash memory interface 30. The IOP 32 may further execute instructions to service other peripheral components 18A-18B. Thus, the processor 22 may perform other computing tasks, or may be powered down to conserve power if there are no other computing tasks to be performed. The IOP 32 may employ any microarchitecture, including scalar, superscalar, pipelined, superpipelined, out of order, in order, speculative, non-speculative, etc., or combinations thereof. The IOP 32 may include circuitry, and optionally may implement microcoding techniques.

[0034] The SIU 16 may be an interconnect over which the memory controller 14, the processor 22 (through the L2 cache 26), the L2 cache 26, and the CDMA controller 20 may communicate. The SIU 16 may implement any type of interconnect (e.g. a bus, a packet interface, point to point links, etc.). The SIU 16 may be a hierarchy of interconnects, in some embodiments.

[0035] The memory controller 14 may be configured to receive memory requests from the system interface unit 16. The memory controller 14 may be configured to access the memory 12 to complete the requests (writing received data to the memory 12 for a write request, or providing data from the memory 12 in response to a read request) using the interface defined for the attached memory 12. The memory controller 14 may be configured to interface with any type of memory 12, such as dynamic random access memory (DRAM), synchronous DRAM (SDRAM), double data rate (DDR, DDR2, DDR3, etc.) SDRAM, RAMBUS DRAM (RDRAM), static RAM (SRAM), etc. The memory may be arranged as multiple banks of memory, such as dual inline memory modules (DIMMs), single inline memory modules (SIMMs), etc. In
one embodiment, one or more memory chips are attached to the integrated circuit 10 in a package on package (POP) or chip-on-chip (COC) configuration.

The memory 12 may include one or more memory devices. Generally, a memory device may be any component that is designed to store data according to an address provided with the data in a write operation, and to supply that data when the address is used in a read operation. Any of the examples of memory types mentioned above may be implemented in a memory device, and the flash memory devices 28A-28B may be memory devices as well. A memory device may be a chip, multiple chips connected to a substrate such as a printed circuit board (e.g. a SIMM or DIMM, or directly connected to a circuit board to which the IC 10 is coupled), etc.

The flash memory interface unit 30 may include circuitry configured to receive read and write requests for the flash memory devices 28A-28B, and configured to interface to the flash memory devices 28A-28B to complete the read/write requests. In one embodiment, the read/write requests may be sourced from the CDMA controller 20. The flash memory interface unit 30 may be programmable via one or more control registers (see Fig. 2 described below) to perform memory transfers to/from the flash memory devices 28A-28B (e.g. via PIO operations). Flash memory devices 28A-28B may be flash memory, a type of non-volatile memory that is known in the art. In other embodiments, other forms of non-volatile memory may be used. For example, battery-backed SRAM, various types of programmable ROMs such as electrically-erasable programmable ROMs (EEPROMs), etc. may be used. In still other embodiments, volatile memory may be used similar to memory 12.

While the present embodiment describes using the command queue (FIFO), macro memory, and/or operand queue (FIFO) in the flash memory interface unit 30, other embodiments may implement the features in any peripheral component, with any type of memory or peripheral interface.

It is noted that other embodiments may include other combinations of components, including subsets or supersets of the components shown in Fig. 1 and/or other components. While one instance of a given component may be shown in Fig. 1, other embodiments may include one or more instances of the given component.

Turning now to Fig. 2, a block diagram of one embodiment of the flash memory interface unit 30 is shown. In the illustrated embodiment, the flash memory interface unit 30 includes a command FIFO 40, a flash memory interface (FMI) control circuit 42, an operand FIFO 46, a macro memory 44, and an operand FIFO 46, and the corresponding FMC control registers 50. The FMC control registers 50 are further coupled to the FMC 48, which is coupled to an external interface to the flash memory devices. The FMC 48 is further coupled to the buffers 52A-52B. The ECC unit 54 is also coupled to the buffers 52A-52B.

The FMI control circuit 42 may be configured to receive PIO operations from the CDMA controller 20. Some PIO operations may be directed to the command FIFO 40, the macro memory 44, or the operand FIFO 46. For example, PIO writes may be used to write commands into the command FIFO 40, to download macros into the macro memory 44, or to write operands into the operand FIFO 46. Addresses may be assigned to each of the FIFO 40, the macro memory 44, and the operand FIFO 46, which may be used in the PIO operands to address the desired resource. For example, the FIFOs 40 and 46 may have a single assigned address since they may operate in a first-in, first-out manner. A PIO write to the address may cause the FMI control circuit 42 to store the data provided with the write in the next open entry in the FIFO 40 or 46. That is, the data may be appended to the tail of the FIFO 40 or 46, where commands or operands are removed from the head of the FIFO 40 or 46. The macro memory 44 may have a range of addresses assigned to it, e.g. an address per word of the macro memory 44. PIO writes to the addresses may store the provided data word into the addressed word of the macro memory 44.

The FMI control circuit 42 may process the commands in the command FIFO 40 to program various FMC control registers 50 to cause the FMC 48 to perform a particular memory transfer to/from the flash memory devices 28A-28B. In one embodiment, the FMC 48 is configured to receive relatively low-level control via the FMC control registers 50, including address, chip enables, transfer commands, etc. Commands in the command FIFO 40 may be interpreted by the FMI control circuit 42 and the corresponding FMC control registers 50 may be written by the FMI control circuit 42. Similarly, commands to wait for an event may be interpreted by the FMI control circuit 42 to read one or more FMC control registers 50 to detect the event. There may also be direct control signals between the FMI control circuit 42 to the FMC 48, in some embodiments (not shown in Fig. 2) which may be driven by the FMI control circuit 42 responsive to commands and/or monitored by the FMI control circuit 42 responsive to commands.

The FMI control circuit 42 may be configured to read the commands from the command FIFO 40 in the order written. More generally, a command queue may be supported (e.g. the command FIFO 40 may not be specified to construct a FIFO, such that each entry in the queue may be concurrently visible to the FMI control circuit 42). Similarly, the operand FIFO 46 may be an operand queue, and the FMI control circuit 42 may read operands from the operand FIFO 46 responsive to the commands in the command queue or the macro memory.
44 in the order the operands were written.

[0044] As mentioned previously, a macro command may be in the command FIFO 40, and the FMI control circuit 42 may perform commands from the macro memory 44 in response to the macro command. In other embodiments, the macro command may be transmitted as a PIO operation to the FMI control circuit 42. In still other embodiments, macro commands may be encountered in the command FIFO 40 or in PIO operations. The macro command may include a starting address in the macro memory and a word count indicating the number of words to read from the macro memory 44. The FMI control circuit 42 may perform the commands in the macro prior to reading the next command in the command FIFO 40. The words in the macro may include operands in addition to commands, in one embodiment. Other embodiments may use an operand count rather than a word count. As mentioned above, the macro command may also include a loop count and the macro may be iterated the number of times indicated by the loop count.

[0045] Reading words from the command FIFO 40 and the operand FIFO 46 may include the FMI control circuit 42 deleting those words from the FIFO. Reading words from the macro memory 44, on the other hand, may not involve deleting the words so that macros may be repeatedly performed.

[0046] The FMC 48 may perform memory transfers in response to the contents of the FMC control registers 50, writing data read from the flash memory devices 28A-28B to the buffers 52A-52B or writing data read from the buffers 52A-52B to the flash memory devices 28A-28B. The buffers 52A-52B may be used in a ping-pong fashion, in which one of the buffers 52A-52B is being filled with data while the other is being drained. For example, reads from the flash memory devices 28A-28B may include the FMC 48 filling one of the buffers 52A-52B while the other buffer 52A-52B is being drained by the CDMA controller 20 performing DMA operations to memory 12. Writes to the flash memory devices 28A-28B may include the CDMA controller 20 filling one of the buffers 52A-52B with data while the FMC 48 drains the other buffer 52A-52B. The ECC unit 54 may generate ECC data for writes to the flash memory devices 28A-28B, and may check the ECC data for reads from the flash memory devices 28A-28B.

[0047] Turning now to Fig. 3, a flowchart is shown illustrating operation of one embodiment of the FMI control circuit 42 in response to receiving a PIO operation from the CDMA controller 20. While the blocks are shown in a particular order for ease of understanding, other orders may be used. Blocks may be performed in parallel in combinatorial logic in the FMI control circuit 42. For example, the decision blocks illustrated in Fig. 3 may be independent and may be performed in parallel. Blocks, combinations of blocks, and/or the flowchart as a whole may be pipelined over multiple clock cycles. The FMI control circuit 42 may be configured to implement the operation illustrated in Fig. 3.
the read/write mode, the FMC 48 may transmit the address bytes on the flash memory interface and may signal an address done interrupt in a status register within the FMC control registers 50. Additionally, the addrX commands may further include waiting for and clearing and address done interrupt in the status register. The addr0 command may differ from the addr1 through addr7 commands in that the address registers and address transfer number register are not programmed. Instead these registers may be preprogrammed using other commands such as the load_next_word or load_from_fifo commands described below. [0052] The cmd command may be used to send a flash memory interface command out on the flash memory interface. In one embodiment, flash memory interface commands are one byte. Accordingly, the operand of the cmd command may be the command byte may be transmitted on the flash memory interface. The FMI control circuit 42 may be configured to pause until the cmd command is completed on the flash memory interface. The cmd command may be equivalent to programming a command register in the FMC control registers 50 with the command byte; setting a command mode bit in another FMC control register 50; and waiting for and clearing a cmd done interrupt in a status register within the FMC control registers 50. Responsive to the setting of the command mode bit, the FMC 48 may be configured to transmit the command byte on the flash memory interface and may write the cmd done interrupt to the status register.[0053] The enable_chip command may be used to write a chip enable register of the FMC control registers 50, which may cause the FMC 48 to drive chip enable signals on the flash memory interface based on the chip enable operand. [0054] The xfer_page command may be used to initiate a page transfer from the flash memory devices 28A-28B. In response to the xfer_page command, the FMI control circuit 42 may be configured to set a start bit in an FMC control register 50 and wait for and clear a page done interrupt bit in another FMC control register 50. In response to the start bit, the FMC 48 may be configured to perform the specified page transfer, and set the page done interrupt upon completion.[0055] There may be various synchronizing command supported by the FMI control circuit 42. Generally, a synchronizing command may be used to specify an event that the FMI control circuit 42 is to monitor for, and may cause the FMI control circuit 42 to wait for the event to occur (i.e. wait until the FMI control circuit 42 detects the event) prior to performing the next command. Thus, synchronizing commands may permit sequences of commands to be preprogrammed, and the synchronizing commands may help ensure the correct timing. For example, multiple page transfers may be preprogrammed, and synchronizing commands may be used to delay programming of the FMC control registers 50 for the next page until the registers are no longer needed for the current page (e.g. after the last data from the page is loaded into the buffer 52A-52B for a read). [0056] In the embodiment of Fig. 4, the synchronizing commands may include wait_for_rdy, pause, timed_wait, and wait_for_int. The wait_for_rdy command may be used to monitor the status of the flash memory devices 28A-28B during a page transfer. The wait_for_rdy command may include waiting for and clearing a specific "done" interrupt (e.g. page done) in the status register of the FMC control registers 50; masking a status byte in the status register with the mask operand, and comparing the masked status byte to the condition operand. If the masked status byte matches the condition operand, the FMI control circuit 42 may be configured to perform the next command. Otherwise, the FMI control circuit 42 may signal an interrupt (e.g. to the IOP 32 or the processor 22, in various embodiments) and may stop performing additional commands until the IOP 32/processor 22 services the interrupt. [0057] The pause command may be used to pause command performance by the FMI control circuit 42. The FMI control circuit 42 may cease performing commands until specifically unpaused by software executing on the IOP 32/processor 22 writing a specified enable bit in one of the FMC control registers 50.[0058] The FMI control circuit 42 may be configured to pause and resume after a number of clock cycles via the timed_wait command. The number of clock cycles is specified as the operand of the timed_wait command. In some embodiments, the timed_wait command may be used to slow down the flash memory interface unit 30, because the performance possible using the command FIFO 40, the macro memory 44, and the operand FIFO 46 may exceed the rate at which activities may be performed by the flash memory devices 28A-28B. [0059] The wait_for_int command may be used to cause the FMI control circuit 42 to wait for a specified interrupt value. The operands may specify the interrupt (irq) to be waited on, and the state of the irq bit to be waited on (e.g. set or clear), using the "bit" operand. [0060] The send_interrupt command may be used to send a specified interrupt to the IOP 32 or processor 22. The operand of the send_interrupt command may specify an interrupt code to write into an interrupt code register of the FMC control registers 50, which may cause the interrupt to be sent.[0061] The load_next_word and load_from_fifo commands may be used to program various registers in the FMC control registers 50. One of the operands of these commands is the register address of the control register to be written. In response to the load_next_word command, the FMI control circuit 42 may read the next word from the command FIFO 40 and write the word to the addressed register. In response to the load_from_fifo command, the FMI control circuit 42 may be configured to read the word at the head of the operand FIFO 46 and write the word to the addressed register. [0062] The macro command may be used to cause the FMI control circuit 42 to read commands from the macro
The FMI control circuit 42 may be configured to poll any register, a length operand, and a loop count operand. The address may identify the first word to be read from the macro memory 44, and the length identifies the length of the macro (e.g., in terms of number of commands or number of words). In one embodiment, the length is the number words. The loop count may indicate a number of iterations of the macro to be performed. In one embodiment, the loop count operand may be one less than the number of iterations (e.g., a loop count of zero is one iteration, a loop count of one is two iterations, etc.). Once a macro completes the next command FIFO 42 may be read (i.e., there may be no return command in the macro).

As noted in the above description, the FMI control circuit 42 may monitor for various interrupts recorded in one or more status registers within the FMC control registers 50 as part of performing certain commands. The FMI control circuit 42 may clear the interrupt and complete the corresponding command. In the absence of commands in the command FIFO 40, the interrupts may instead be forwarded to the IOP 32/processor 22 (if enabled). Accordingly, PIO write operations to the FMC control registers 50 and interrupts to the IOP 32/processor 22 may be another mechanism to perform memory transfers to/from the flash memory devices 28A-28B.

Turning now to Fig. 5, a flowchart is shown illustrating operation of one embodiment of the FMI control circuit 42 to process a command. While the blocks are shown in a particular order for ease of understanding, other orders may be used. Blocks may be performed in parallel in combinatorial logic in the FMI control circuit 42. Blocks, combinations of blocks, and/or the flowchart as a whole may be pipelined over multiple clock cycles. The FMI control circuit 42 may be configured to implement the operation illustrated in Fig. 5.

The FMI control circuit 42 may be configured to read a command from the command FIFO 40 (block 80). If the command is not a macro command (decision block 82, "no" leg), the FMI control circuit 42 may be configured to perform the command (block 84). Once the command completes, the FMI control circuit 42 may be configured to check a word count used to determine if a macro has reached its end. If the command is not part of a macro, the word count may be zero (decision block 86, "no" leg). The FMI control circuit may be configured to check the loop count associated with the macro command. If the command is not part of a macro, the loop count may be zero (decision block 95, "no" leg). The FMI control circuit 42 may be configured to determine if there is another valid command in the command FIFO 40 (decision block 88). That is, the FMI control circuit 42 may be configured to determine if the command FIFO 40 is empty. If there is another valid command (decision block 88, "yes" leg), the FMI control circuit 42 may be configured to read and process the next command. Otherwise, the FMI control circuit 42's command processing circuitry may be idle until another valid command is written to the command FIFO 40 (decision block 88, "no" leg).

If the command is a macro command (decision block 82, "yes" leg), the FMI control circuit 42 may be configured to initialize the word count to the length operand of the macro command and to initialize the loop count to the loop count operand of the macro command (block 90). The FMI control circuit 42 may also read a command from the macro memory 44 (block 92). Specifically, in this case, the FMI control circuit 42 may read the first word from the address in the macro memory 44 provided as the address operand of the macro command. The FMI control circuit 42 may be configured to perform the command (block 84), and may be configured to check the word count. The word count may be greater than zero (decision block 86, "yes" leg), and the FMI control circuit 42 may be configured to decrement the word count and to read the next command from the macro memory 44 (e.g. by incrementing the address) (blocks 94 and 96). The FMI control circuit 42 may be configured to process the next command (returning to decision block 82 in the flowchart of Fig. 5). If the word count is zero (decision block 86, "no" leg), the FMI control circuit 42 may be configured to check the loop count. If the loop count is greater than zero (decision block 95, "yes" leg), another iteration of the macro is to be performed. The FMI control circuit 42 may decrement the loop count (block 97), reinitialize the word count and the macro address (block 99), and read the next command from the macro memory 44 (i.e. the first command of the macro) (block 96). If both the word count and loop count are zero (decision block 86 and 88, "no" legs), the macro is complete and the FMI control circuit 42 may check for the next valid command in the command queue 40 (decision block 88).

It is noted that, since each command is checked for being a macro command, macro commands may be stored in the macro memory 44 as well. Accordingly, macros may be "nested," although the last macro to be performed returns to the command FIFO 40 so there isn't true nesting in the sense that macros do not return to macros that called them.

Turning now to Fig. 6, a block diagram of an example of a use of macros to perform a multiple page write to a flash memory device 28A or 28B is shown. A contents of the macro memory 44 is shown, including three sections of commands. Between macro memory address 0 and N-1, N words of macro 100 to complete a write to the previous page are stored. Between macro memory address N and N+M-1, M words of macro 102 to start a write to a next page are stored. Between macro memory address N+M and N+M+P-1, P words of macro 104 are stored to finish a last page of a write to memory. A set of commands in the command FIFO 40 are illustrated in Fig. 6, with a head of the FIFO at the
top of the command FIFO 42 and the subsequent commands in the FIFO proceeding in order down the command FIFO 40 as illustrated in Fig. 6. The first command is macro N, M. The command calls the macro 104, beginning at word N, and performs M words (i.e. the macro 102 as illustrated in Fig. 6). Thus, the write to the first page is initialized. Subsequent page writes may be performed using the macro 0, N+M commands. These commands cause the macro 100 and the macro 102 to be performed. The write to the previous page may be completed (macro 100) and the write to the next page may be started (macro 102). The last page may be written using the macro 0, N+M+P command. This command causes the macros 100, 102, and 104 to be performed, completing the write to the second to last page (macro 100), performing the write to the last page (macro 102), and completing the write to the last page and closing the flash memory device 28A or 28B (macro 104). In this example, the loop count operand of each macro command is zero (one iteration). However, in another example, shown below the first example in Fig. 6, the loop count operand may be used to make the commands in the command queue even more efficient. The loop count of the macro N, M command for the first page and the macro 0, N+M+P command for the last page may still be zero, specifying one iteration. However, the middle pages of the write may all be accomplished using one macro command (macro 0, N + M) with a loop count operand equal to the page count (C) minus 3. The loop count is C-3 to account for the first and last page, as well as the fact that the loop count operand is one less than the desired number of iterations in this embodiment. As the macros 100, 102, and 104 illustrate, through careful arrangement of the macros in the macro memory 44, dense and efficient macros may result. The macros may employ load_from_fifo commands to use different operands for each page write operand, and the operands for each page may be loaded into the operand FIFO 46 prior to initiating the commands in the command FIFO 40.

[0071] The commands included in the macro 102 may be accomplished using one macro command (macro 0, N + M) with a loop count operand equal to the page count (C) minus 3. The loop count is C-3 to account for the first and last page, as well as the fact that the loop count operand is one less than the desired number of iterations in this embodiment. As the macros 100, 102, and 104 illustrate, through careful arrangement of the macros in the macro memory 44, dense and efficient macros may result. The macros may employ load_from_fifo commands to use different operands for each page write operand, and the operands for each page may be loaded into the operand FIFO 46 prior to initiating the commands in the command FIFO 40.

[0072] Turning now to Fig. 7, a flowchart illustrating operation of a flash code to be executed by the IOP 32 and/or the processor 22 is shown. While the blocks are shown in a particular order for ease of understanding, other orders may be used. The flash code may include instructions which, when executed by the IOP 32 and/or the processor 22, may implement the operation illustrated in Fig. 7.

[0073] The flash code may be executed at any time during operation of the integrated circuit 10. For example, the flash code may be executed to initialize the flash memory interface unit 30. The flash code may also be executed at any time that the flash memory 30 has been idle but is to be accessed, to reconfigure the macros in the macro memory 44, etc.

[0074] The flash code may download any desired macros to the macro memory 44 (block 110). If the macros already stored in the macro memory 44 are the desired macros, or if there are no desired macros, block 110 may be skipped. The flash code may also download any operands to be used by the commands or the macros (block 112), and block 112 may be skipped if there are no operands to be downloaded. The flash code may download the commands to be performed (block 114), and command performance may begin in the flash memory interface unit 30. If additional commands are ready to be downloaded (decision block 116, "yes" leg), the flash code may download the additional commands (block 114). If new operands or macros are ready to be downloaded (decision block 118, "yes" leg), the flash code may return to blocks 110 and/or 112 to download them.

System and Computer Accessible Storage Medium

[0075] Turning next to Fig. 8, a block diagram of one embodiment of a system 150 is shown. In the illustrated embodiment, the system 150 includes at least one instance of an integrated circuit 10 (from Fig. 1) coupled to one or more peripherals 154 and an external memory 158. The external memory 158 may include the memory 12. A power supply 156 is also provided which supplies the supply voltages to the integrated circuit 10 as well as one or more supply voltages to the memory 158 and/or the peripherals 154. In some embodiments, more than one instance of the integrated circuit 10 may be included (and more than one external memory 158 may be included as well).

[0076] The peripherals 154 may include any desired circuitry, depending on the type of system 150. For example, in one embodiment, the system 150 may be a mobile device (e.g. personal digital assistant (PDA), smart phone, etc.) and the peripherals 154 may include devices for various types of wireless communication, such as wifi, Bluetooth, cellular, global positioning system, etc. The peripherals 154 may also include additional storage, including RAM storage, solid state storage, or disk storage. The peripherals 154 may include user interface devices such as a display screen, including touch display screens or multitouch display screens, keyboard or other input devices, microphones, speakers, etc. In other embodiments, the system 150 may be any type of computing system (e.g. desktop personal computer, laptop, workstation, net top etc.).

[0077] The external memory 158 may include any type of memory. For example, the external memory 158 may
be SRAM, dynamic RAM (DRAM) such as synchronous DRAM (SDRAM), double data rate (DDR, DDR2, DDR3, etc.) SDRAM, RAMBUS DRAM, etc. The external memory 158 may include one or more memory modules to which the memory devices are mounted, such as single inline memory modules (SIMMs), dual inline memory modules (DIMMs), etc.

[0078] Turning now to Fig. 9, a block diagram of a computer accessible storage medium 200 is shown. Generally speaking, a computer accessible storage medium may include any storage media accessible by a computer during use to provide instructions and/or data to the computer. For example, a computer accessible storage medium may include storage media such as magnetic or optical media, e.g., disk (fixed or removable), tape, CD-ROM, DVD-ROM, CD-R, CD-RW, DVD-R, DVD-RW, or Blu-Ray. Storage media may further include volatile or non-volatile memory media such as RAM (e.g. synchronous dynamic RAM (SDRAM), Rambus DRAM (RDRAM), static RAM (SRAM), etc.), ROM, Flash memory, non-volatile memory (e.g. Flash memory) accessible via a peripheral interface such as the Universal Serial Bus (USB) interface, a flash memory interface (FMI), a serial peripheral interface (SPI), etc. Storage media may include microelectromechanical systems (MEMS), as well as storage media accessible via a communication medium such as a network and/or a wireless link. The computer accessible storage medium 200 in Fig. 5 may store flash code 202, which may include code by the IOP 32 and/or the processor 22. The flash code 202 may include instructions which, when executed, implement the operation described above with regard to Fig. 7. Generally, the computer accessible storage medium 200 may store any set of instructions which, when executed, implement a portion or all of the operation shown in Fig. 7. Furthermore, the computer accessible storage medium 200 may store one or more macros 204 to be downloaded to the macro memory 44, one or more operands to be transferred, and wherein the plurality of commands include one or more macros 204 to be downloaded to the operand FIFO 36, and/or one or more commands to be transferred, and wherein the plurality of commands that cause a transfer on the external interface; a macro memory (44) configured to store a second plurality of commands, wherein the plurality of commands in the command queue (40) are removed from the command queue in response to performing the plurality of commands, and wherein the second plurality of commands remain in the macro memory (44) even when the second plurality of commands have been performed, wherein at least one of the plurality of commands in the command queue (40) is a macro command that causes commands in the macro memory (44) to be performed, and wherein the macro command specifies an address of a first command in the macro memory (44) that is to be executed and a number of words to be read beginning with the first command; and a control circuit (42) coupled to the command queue (40) and to the controller (48), wherein the control circuit (42) is configured to perform the plurality of commands from the command queue (40) and is configured to initiate corresponding operations in the controller (48) to perform the transfer, and wherein the control circuit (42) is configured to return the number of words from the macro memory (44) in response to the macro command and subsequently perform the next command in the command queue (40) after the macro command without requiring a return command in the macro memory (44), whereby the second plurality of commands excludes return commands to return to the command queue (40).

2. The apparatus as recited in claim 1 further comprising a plurality of control registers (50) coupled to the controller (48) the control circuit (42), wherein the controller (48) is configured to communicate on the external interface (30) responsive to a content of the plurality of control registers (50), and wherein the plurality of commands include one or more commands that cause the control circuit (42) to update one or more of the plurality of control registers (50).

3. The apparatus as recited in claim 1 or 2 wherein the control circuit (42) is configured to receive the plurality of commands on an internal interface within the integrated circuit (10), and wherein the control circuit (42) is configured to receive the plurality of commands into the command queue (40) responsive to receiving the plurality of commands.

4. The apparatus as recited in any of claims 1-3 wherein the external interface (30) is a flash memory interface, and wherein the plurality of commands include a first command that causes the controller to drive an address to one or more flash memory devices
(28A, 28B) that are coupled to the flash memory interface (30).

5. The apparatus as recited in claim 4 wherein the plurality of commands include a second command that causes the controller (48) to drive a specified one or more chip enable signals to the one or more memory device (28A, 28B).

6. The apparatus as recited in claim 4 wherein the plurality of commands include a second command that causes the controller (48) to transfer a page of data between the integrated circuit (10) and one or more memory devices (28A, 28B).

7. The apparatus as recited in claim 1 wherein the macro command further specifies a loop count operand that indicates a number of iterations of the second plurality of commands that are to be performed.

8. The apparatus as recited in claim 7 wherein the second plurality of commands include a second macro command specifying a second address of a second command in the macro memory (44) and a second number of words to be read, and wherein the controller (42) is configured to return to the command queue (40) subsequent to performing commands in the second number of words beginning with the second command.

9. The apparatus as recited in any of claims 1-8 wherein the interface unit (30) comprises an operand queue (46) configured to store operand data accessible by commands in the command queue (40) and in the macro memory (44).

10. A method comprising:

reading a plurality of commands from a command queue (40) a memory interface (30) unit of an integrated circuit (10) wherein the memory interface unit (30) further includes a macro memory (44) storing a second plurality of commands, wherein the plurality of commands in the command queue (40) are removed from the command queue (40) in response to performing the plurality of commands, and wherein the second plurality of commands remain in the macro memory (44) even when the second plurality of commands have been performed, wherein at least one of the plurality of commands in the command queue (40) is a macro command that causes commands in the macro memory (44) to be performed, and wherein the macro command specifies an address of a first command in the macro memory (44) that is to be executed and a number of words to be read beginning with the first command;

reading the number of words from the macro memory (44) in response to the macro command and subsequently performing the next command in the command queue (40) after the macro command without requiring a return command in the macro memory (44), whereby the second plurality of commands excludes return commands to return to the command queue (40); and

causing a controller (48) to communicate on an external interface (30) of the integrated circuit (10) one or more memory devices (28A, 28B) coupled to the external interface (30) responsive to the plurality of commands in the command queue (40), wherein the plurality of commands cause a memory transfer between the one or more memory devices (28A, 28B) and the integrated circuit (10), wherein a memory transfer comprises one or more pages of data.

11. The method as recited in claim 10 wherein the plurality of commands include a first command that causes the controller (48) to transmit an address to the one or more memory devices (28A, 28B), a second command that causes the controller (48) to transmit a set of chip enables to the one or more memory devices (28A, 28B), an at least one third command that causes the controller (48) to transfer a page of data.

12. The method as recited in claim 11 wherein the plurality of commands comprise a first command that causes the controller (48) to transmit a corresponding command to the one or more memory device (28A, 28B) on the interface, (30) the corresponding command defined in a memory interface protocol for the one or more memory devices (28A, 28B).

13. The method as recited in claim 10 wherein the macro command further specifies a loop count operand that indicates a number of iterations of the second plurality of commands that are to be performed.

14. The method as recited in claim 13 wherein the second plurality of commands include a second macro command specifying a second address of a second command in the macro memory (44) and a second number of words to be read, and the method further comprising performing the second number of words beginning with the second command and subsequently returning to the command queue (40) responsive to the second macro command.

15. The method as recited in any of claims 10-14 wherein the interface unit (30) comprises an operand queue (46) configured to store operand data accessible by commands in the command queue (40) and in the macro memory (44).
Patentansprüche

1. Vorrichtung zum Steuern einer externen Schnittstelle (30) für eine integrierte Schaltung (10), wobei die Vorrichtung aufweist:

   eine Steuerung (48), die konfiguriert ist, auf der externen Schnittstelle (30) zu kommunizieren;
   eine Anweisungswarteschlange (40), die konfiguriert ist, eine Vielzahl an Anweisungen zu speichern, die eine Übertragung auf der externen Schnittstelle (30) auslösen;

   einen Makrospeicher (44), der konfiguriert ist, eine zweite Vielzahl an Anweisungen zu speichern, wobei die Vielzahl an Anweisungen in der Anweisungswarteschlange (40) aus der Anweisungswarteschlange in Erwiderung auf ein Ausführen der Vielzahl an Anweisungen entfärnt wird und wobei die zweite Vielzahl an Anweisungen in dem Makrospeicher (44) verbleibt selbst wenn die zweite Vielzahl an Anweisungen ausgeführt wurde, wobei zumindest eine der Vielzahl an Anweisungen in der Anweisungswarteschlange (40) eine Makroanweisung ist, die das Ausführen der Anweisungen in dem Makrospeicher (44) auslöst, und wobei die Makroanweisung eine Adresse einer ersten auszuführenden Anweisung in dem Makrospeicher (44) und eine Anzahl an Wörtern spezifiziert, die mit der ersten Anweisung startend zu lesen sind; und

   eine Steuerungsschaltung (42), die an die Anweisungswarteschlange (40) und die Steuerung (48) gekoppelt ist, wobei die Steuerungsschaltung (42) konfiguriert ist, die Vielzahl an Anweisungen aus der Anweisungswarteschlange (40) zu lesen, und konfiguriert ist, die entsprechenden Operationen in der Steuerung (48) zu initiieren, um die Übertragung auszuführen, und wobei die Steuerungsschaltung (42) konfiguriert ist, die Anzahl an Wörtern aus dem Makrospeicher (44) in Erwiderung auf die Makroanweisung zu lesen und anschließend, ohne dass es einer Rückkehranweisung in dem Makrospeicher (44) bedarf, die nächste Anweisung in der Anweisungswarteschlange (40) nach der Makroanweisung auszuführen, wobei die zweite Vielzahl an Anweisungen Rückkehranweisungen zum Zurückkehren in die Anweisungswarteschlange (40) ausschließt.

2. Vorrichtung nach Anspruch 1, ferner aufweisend eine Vielzahl an Steuerungsregistern (50), die an die Steuerung (48) und die Steuerungsschaltung (42) gekoppelt sind, wobei die Steuerung (48) konfiguriert ist, auf der externen Schnittstelle (30) in Erwiderung auf einen Inhalt der Vielzahl an Steuerungsregistern (50) zu kommunizieren, und wobei die Vielzahl an Anweisungen eine oder mehrere Anweisungen enthält, die die Steuerungsschaltung (42) veranlassen, einen oder mehrere der Vielzahl an Steuerungsregistern (50) zu aktualisieren.

3. Vorrichtung nach Anspruch 1 oder 2, wobei die Steuerungsschaltung (42) konfiguriert ist, die Vielzahl an Anweisungen auf einer internen Schnittstelle innerhalb der integrierten Schaltung (10) zu empfangen, und wobei die Steuerungsschaltung (42) konfiguriert ist, die Vielzahl an Anweisungen in die Anweisungswarteschlange (40) in Erwiderung auf das Empfangen der Vielzahl an Anweisungen zu schreiben.

4. Vorrichtung nach einem der Ansprüche 1 bis 3, wobei die externe Schnittstelle (30) eine Flash-Speicherschnittstelle ist und wobei die Vielzahl an Anweisungen eine erste Anweisung aufweist, welche die Steuerung veranlasst, eine Adresse zu einer oder mehreren Flash-Speichervorrichtungen (28A, 28B) zu steuern, die an die Flash-Speicherschnittstelle (30) gekoppelt sind.

5. Vorrichtung nach Anspruch 4, wobei die Vielzahl an Anweisungen eine zweite Anweisung aufweist, welche die Steuerung (48) veranlasst, einen oder mehrere spezifizierte Chipfreigabesignale zu der einen oder zu den mehreren Speichervorrichtungen (28A, 28B) zu steuern.

6. Vorrichtung nach Anspruch 4, wobei die Vielzahl an Anweisungen eine zweite Anweisung aufweist, welche die Steuerung (48) veranlasst, eine Datenseite zwischen der integrierten Schaltung (10) und einer oder mehreren Speichervorrichtungen (28A, 28B) zu übertragen.

7. Vorrichtung nach Anspruch 1, wobei die Makroanweisung ferner einen Schleifenzähloperanden spezifiziert, der eine Anzahl an Iterationen der zweiten Vielzahl an Anweisungen, die auszuführen sind, anzeigt.

8. Vorrichtung nach Anspruch 7, wobei die zweite Vielzahl an Anweisungen eine zweite Makroanweisung aufweist, die eine zweite Adresse einer zweiten Anweisung in dem Makrospeicher (44) und eine zweite Anzahl an Wörtern, die zu lesen sind, aufweist und wobei die Steuerungsschaltung (42) konfiguriert ist, im Anschluss an das Ausführen von Anweisungen in der zweiten Anzahl an Wörtern, die mit der zweiten Anweisung starten zu der Anweisungswarteschlange (40) zurückzukehren.

9. Vorrichtung nach einem der Ansprüche 1 bis 8, wobei die Schnittstelleneinheit (30) eine Operandenwarteschlange (46) aufweist, die konfiguriert ist,
Verfahren, das aufweist:

Lesen einer Vielzahl an Anweisungen aus einer Anweisungswarteschlange (40) in einer Speicherschnittstelleineinheit (30) einer integrierten Schaltung (10), wobei die Speicherschnittstelleineinheit (30) ferner einen Makrospeicher (44) aufweist, der eine zweite Vielzahl an Anweisungen speichert, wobei die Vielzahl an Anweisungen in der Anweisungswarteschlange (40) aus der Anweisungswarteschlange (40) in Erweiterung auf das Ausführen der Vielzahl an Anweisungen entfernt wird und wobei die zweite Vielzahl an Anweisungen in dem Makrospeicher (44) verbleibt selbst wenn die zweite Vielzahl an Anweisungen ausgeführt wurde, wobei zumindest eine der Vielzahl an Anweisungen in der Anweisungswarteschlange (40) eine Makroanweisung ist, die das Ausführen der Anweisungen in dem Makrospeicher (44) auslöst, und wobei die Makroanweisung eine Adresse einer ersten auszuführenden Anweisung in dem Makrospeicher (44) und eine Anzahl an Wörtern spezifiziert, die mit der ersten Anweisung startend zu lesen sind; Lesen der Vielzahl an Wörtern aus dem Makrospeicher (44) in Erwiderung auf die Makroanweisung und anschließend, ohne dass es einer Rückkehranweisung in dem Makrospeicher (44) bedarf, Ausführen der nächsten Anweisung in der Anweisungswarteschlange (40) nach der Makroanweisung, wobei die zweite Vielzahl an Anweisungen Rückkehranweisungen zum Zurückkehren in die Anweisungswarteschlange (40) ausschließt; und Veranlassen einer Steuerung (48), in Erweiterung auf die Vielzahl an Anweisungen in der Anweisungswarteschlange (40), auf einer externen Schnittstelle (30) der integrierten Schaltung (10) mit einer oder mehreren Speichervorratsteilnehmer (28A, 28B) zu kommunizieren, die an die externe Schnittstelle (30) gekoppelt sind, wobei die Vielzahl an Anweisungen einen Speichertransfer zwischen einer oder mehreren Speichervorratsteilnehmer (28A, 28B) und der integrierten Schaltung (19) auslöst, wobei ein Speichertransfer eine oder mehrere Datenseiten aufweist.

Verfahren nach Anspruch 10, wobei die Vielzahl an Anweisungen aufweist: eine erste Anweisung, welche die Steuerung (48) veranlasst, eine Adresse an die eine oder an die mehreren Speichervorratsteilnehmer (28A, 28B) zu übertragen, eine zweite Anweisungsveranlassung (48) veranlasst, eine Menge an Chip-Freigaben an die eine oder an die mehreren Speichervorratsteilnehmer (28A, 28B) zu übertragen, und zumindest eine dritte Anweisung, die die Steuerung (48) veranlasst, eine Datenseite zu übertragen.

Verfahren nach Anspruch 11, wobei die Vielzahl an Anweisungen eine erste Anweisung aufweist, die die Steuerung (48) veranlasst, eine entsprechende Anweisung an die eine oder an die mehreren Speichervorratsteilnehmer (28A, 28B) auf der Schnittstelle (30) zu übertragen, wobei die entsprechende Anweisung in einem Speicherschnittstellenprotokoll für die eine oder die mehreren Speichervorratsteilnehmer (28A, 28B) aufweist.

Verfahren nach Anspruch 10, wobei die MAKROanweisung ferner einen Schleifenzähloperanden spezifiziert, der eine Anzahl an Iterationen der zweiten Vielzahl an Anweisungen, die auszuführen sind, anzeigt.

Vorrichtung nach Anspruch 13, wobei die zweite Vielzahl an Anweisungen eine zweite MAKROanweisung aufweist, die eine zweite Adresse einer zweiten Anweisung in dem Makrospeicher (44) und eine zweite Anzahl an Wörtern, die zu lesen sind, aufweist und wobei das Verfahren ferner ein Ausführen der zweiten Anzahl an Wörtern, die mit der zweiten Anweisung starten, und anschließendes Zurückkehren zu der Anweisungswarteschlange (40) in Erweiterung auf die zweite MAKROanweisung aufweist.

Vorrichtung nach einem der Ansprüche 10 bis 14, wobei die Schnittstelleineinheit (30) eine Operaendatenverarbeitung (40) aufweist, die konfiguriert ist, Operandendaten zu speichern, die durch Anweisungen in der Anweisungswarteschlange (40) und in dem Makrospeicher (44) zugreifbar sind.

Revendications

1. Un dispositif de contrôle d’une interface externe (30) pour un circuit intégré (10), le dispositif comprenant : un contrôleur (48) configuré pour communiquer sur l’interface externe (30) ; une file d’attente de commandes (40) configurée pour mémoriser une pluralité de commandes qui provoquent un transfert sur l’interface externe ; une macromémoire (44) configurée pour mémoriser une seconde pluralité de commandes, la pluralité de commandes dans la file d’attente de commandes (40) étant retirée de la file d’attente de commandes en réponse à l’exécution de la pluralité de commandes et, la seconde pluralité de commandes demeurant dans la macromémoire (44) même lorsque la seconde pluralité de commandes ont été exécutées,
au moins l’une de la pluralité de commandes dans la file d’attente de commandes (40) étant une macrocommande qui provoque l’exécution de commandes dans la macromémoire (44), et la macrocommande spécifiant une adresse d’une première commande dans la macromémoire (44) qui doit être exécutée et un nombre de mots à lire en commençant à la première commande ; et
un circuit de contrôle (42) couplé à la file d’attente de commandes (40) et au contrôleur (48), le circuit de contrôle (42) étant configuré pour lire la pluralité de commandes à partir de la file d’attente de commandes (40) et étant configuré pour initier des opérations correspondantes dans le contrôleur (48) pour exécuter le transfert, et le circuit de contrôle (42) étant configuré pour lire le nombre de mots à partir de la macromémoire (44) en réponse à la macrocommande et exécuter ensuite la commande suivante dans la file d’attente de commandes (40) après la macrocommande sans nécessiter de commande de retour dans la macromémoire (44), de sorte que la seconde pluralité de commandes excluent le retour de commandes de retour à la file d’attente de commandes (40).

2. Le dispositif de la revendication 1, comprenant en outre une pluralité de registres de contrôle (50) couplés au contrôleur (48) et au circuit de contrôle (42), le contrôleur (48) étant configuré pour communiquer sur l’interface externe (30) en réponse à un contenu de la pluralité de registres de contrôle (50), et la pluralité de commandes incluant une ou plusieurs commandes qui provoquent la mise à jour par le circuit de contrôle (42) d’un ou plusieurs de la pluralité de registres de contrôle (50).

3. Le dispositif de la revendication 1 ou 2, dans lequel le circuit de contrôle (42) est configuré pour recevoir la pluralité de commandes sur une interface interne au sein du circuit intégré (10), et dans lequel le circuit de contrôle (42) est configuré pour inscrire la pluralité de commandes dans la file d’attente de commandes (40) en réponse à la réception de la pluralité de commandes.

4. Le dispositif de l’une des revendications 1 à 3, dans lequel l’interface externe (30) est une interface de mémoire flash, et dans lequel la pluralité de commandes comprennent une première commande qui provoque le pilotage par le contrôleur d’une adresse vers un ou plusieurs composants de mémoire flash (28A, 28B) qui sont couplés à l’interface de mémoire flash (30).

5. Le dispositif de la revendication 4, dans lequel la pluralité de commandes comprend une seconde commande qui provoque le pilotage par le contrôleur (48) d’un ou plusieurs signaux d’activation de puce spécifiée vers les un ou plusieurs composants de mémoire (28A, 28B).

6. Le dispositif de la revendication 4, dans lequel la pluralité de commandes comprend une seconde commande qui provoque le transfert par le contrôleur (48) d’une page de données entre le circuit intégré (10) et un ou plusieurs composants de mémoire (28A, 28B).

7. Le dispositif de la revendication 1, dans lequel la macrocommande spécifie en outre un opérande de comptage de boucle qui indique un nombre d’itérations de la seconde pluralité de commandes qui doivent être exécutées.

8. Le dispositif de la revendication 7, dans lequel la seconde pluralité de commandes comprennent une seconde macrocommande spécifiant une seconde adresse d’une seconde commande dans la macromémoire (44) et un second nombre de mots à lire, et dans lequel le circuit de contrôle (42) est configuré pour retourner à la file d’attente de commandes (40) à la suite de l’exécution de commandes dans le second nombre de mots en commençant à la seconde commande.

9. Le dispositif de l’une des revendications 1 à 8, dans lequel l’unité d’interfaçage (30) comprend une file d’attente d’opérandes (46) configurée pour mémo- riser des données d’opérande accessibles par des commandes dans la file d’attente de commandes (40) et dans la macromémoire (44).

10. Un procédé comprenant :
lire une pluralité de commandes depuis une file d’attente de commandes (40) dans une unité d’interfaçage mémoire (30) d’un circuit intégré (10), l’unité d’interfaçage mémoire (30) comprenant en outre une macromémoire (44) mémorisant une seconde pluralité de commandes, la pluralité de commandes dans la file d’attente de commandes (40) étant retirée de la file d’attente de commandes (40) en réponse à l’exécution de la pluralité de commandes, et la seconde pluralité de commandes demeurant dans la macromémoire (44) même lorsque la seconde pluralité de commandes ont été exécutées, au moins l’une de la pluralité de commandes dans la file d’attente de commandes (40) étant une macrocommande qui provoque l’exécution de commandes dans la macromémoire (44), et la macrocommande spécifiant une adresse d’une première commande dans la macromémoire (44) qui doit être exécutée et un nombre de mots à lire en commençant à la première commande ;
lire le nombre de mots à partir de la macromémoire (44) en réponse à la macrocommande et exécuter ensuite la commande suivante dans la file d’attente
de commandes (40) après la macrocommande sans nécessiter de commande de retour dans la macro-mémoire (44), de sorte que la seconde pluralité de commandes excluent le retour de commandes de retour à la file d'attente de commandes (40) ; et faire en sorte qu'un contrôleur (48) communique sur une interface externe (30) du circuit intégré (10) vers un ou plusieurs composants de mémoire (28A, 28B) couplés à l'interface externe (30) en réponse à la pluralité de commandes dans la file d'attente de commandes (40), la pluralité de commandes provoquant un transfert mémoire entre les un ou plusieurs composants de mémoire (28A, 28B) et le circuit intégré (10), un transfert mémoire comprenant une ou plusieurs pages de données.

11. Le procédé de la revendication 10, dans lequel la pluralité de commandes comprennent une première commande qui provoque la transmission par le contrôleur (48) d'une adresse vers les un ou plusieurs composants de mémoire (28A, 28B), une seconde commande qui provoque la transmission par le contrôleur (48) d'un jeu d'activation de puces vers les un ou plusieurs composants de mémoire (28A, 28B), et au moins une troisième commande qui provoque le transfert par le contrôleur (48) d'une page de données.

12. Le procédé de la revendication 11, dans lequel la pluralité de commandes comprennent une première commande qui provoque la transmission par le contrôleur (48) d'une commande correspondante vers les un ou plusieurs composants de mémoire (28A, 28B) sur l'interface externe (30), la commande correspondante étant définie dans un protocole d'interfaçage mémoire pour les un ou plusieurs composants de mémoire (28A, 28B).

13. Le procédé de la revendication 10, dans lequel la macrocommande spécifie en outre un opérande de comptage de boucle qui indique un nombre d'itérations de la seconde pluralité de commandes qui doivent être exécutées.

14. Le procédé de la revendication 13, dans lequel la seconde pluralité de commandes comprennent une seconde macrocommande spécifiant une seconde adresse d'une seconde commande dans la macro-mémoire (44) et un second nombre de mots à lire, et le procédé comprenant en outre l'exécution du second nombre de mots commençant avec la seconde commande et ensuite le retour à la file d'attente de commandes (40) en réponse à la seconde macrocommande.

15. Le procédé de l'une des revendications 10 à 14, dans lequel l'unité d'interfaçage (30) comprend une file d'attente d'opérandes (46) configurée pour mémo-
