Note: Within nine months of the publication of the mention of the grant of the European patent in the European Patent Bulletin, any person may give notice to the European Patent Office of opposition to that patent, in accordance with the Implementing Regulations. Notice of opposition shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
This invention relates to the treatment and processing of vegetable oils.

Vegetable oils are valuable commercial products that are used, for example, in the food industry. The oils can be used as such or modified before use. Modification is sometimes necessary or desirable in order to make the vegetable oil more suitable for use in a given application. For example, vegetable oils are typically liquid at room temperature and are generally too low melting to be used as hardstock fats for margarines and spreads. Consequently, vegetable oils for use as hardstocks have been treated to increase their solid fat content at room temperature.

Processes for modifying vegetable oils on an industrial scale have traditionally involved chemical reactions such as hydrogenation in the presence of a metal catalyst or interesterification in the presence of a metal salt. Hydrogenation increases the level of saturated fatty acids in the oil and so raises the solid fat content at a given temperature. The randomisation of fatty acid residues on the triglycerides that takes place during interesterification also increases the solid fat content.

More recently, it has become possible to carry out interesterification in the presence of an enzyme. The advantages of enzymatic processes include the mild conditions that can be employed and the potential to omit added metals or metal salts from the process. Examples of disclosures of using enzymatic interesterification in the production of hardstocks for margarines and spreads can be found in WO 2005/071053 and WO 96/19115.

Enzymatic interesterification requires a high efficiency for the process in order to make it commercially viable. One approach to improving efficiency has been to try to increase the life of the enzyme.

US 7,452,702 describes a method for producing fats or oils by deodorization alone or deodorization and purification of the initial substrate, to improve the productivity of enzymatic interesterification. This patent lists a variety of possible oils and methods of deodorization and purification.

US 6,027,755 relates to bleaching clays that can be used to purify edible or inedible oils. The bleaching agents are formed by the agglomeration of acid-activated clay particles.

There remains a need to improve the pretreatment of vegetable oils prior to enzymatic reaction. In particular, it has been found that the productivity of the enzyme remains low for commercial application on an industrial scale.

We have found that the type of bleaching earth that is used for pretreating the oil greatly affects the productivity of the enzymatic reaction.

According to the present invention, there is provided a process for interesterifying a vegetable oil, which comprises treating the vegetable oil by contacting the vegetable oil with a natural adsorbent to give a pH in the range of from 6 to 8, separating the oil from the adsorbent and reacting the treated oil in the presence of an enzymatic catalyst for interesterification, where the natural adsorbent is a clay having an intergrowth of two or more materials.

A further aspect of the invention is a method of increasing the productivity of an enzyme in the process for interesterifying a vegetable oil according to claim 1.

Also provided by the invention is a method of producing a hardstock for a margarine, which comprises interesterifying a vegetable oil according to the process of the invention.

The invention also contemplates a method of treating a vegetable oil, which comprises: contacting the vegetable oil with a natural adsorbent in the presence of water; and separating the oil from the adsorbent.

Further contemplated by the invention is a method of treating a vegetable oil, which comprises: contacting the vegetable oil with a natural adsorbent in the presence of water; and separating the oil from the adsorbent, wherein the resulting oil comprises less than 1 % by weight of soaps.

Vegetable oils that are useful in the invention are typically oils that comprise as the major component (i.e., greater than 50 % by weight, generally greater than 75 % or greater than 90 % by weight) glycerides of fatty acids. The term "oils" includes both oils and fats. The glycerides are mostly triglycerides (i.e., more than 90 % by weight of the glycerides are typically triglycerides) but they may include some mono- and di-glycerides. The term "fatty acids" as used herein refers to C12 to C24 saturated or unsaturated (including mono- and poly- unsaturated) straight chain carboxylic acids.

Vegetable oils that may be used in the invention include palm oil, palm kernel oil, palm stearin, palm kernel olein, palm kernel stearin, cocoa butter, cocoa butter substitutes, illipe fat, shea fat, canola oil, castor oil, coconut oil, coriander oil, corn oil, cottonseed oil, hazelnut oil, hempseed oil, linseed oil, mango kernel oil, olive oil, peanut oil, rapeseed oil, rice bran oil, safflower oil, soybean oil, and sunflower oil. The oils may be used singly or as a mixture of one or more different types of oil.

Preferred vegetable oils are from palm. Preferably, the oil comprises one or more oils derived from palm. Oils derived from palm include palm oil, palm oil stearin, palm olein, palm kernel oil, palm kernel stearin and palm kernel olein. More preferably, the oil comprises a mixture (i.e., a blend) of palm oil stearin and palm kernel oil.

Blends of palm oils (such as palm oil stearin and palm kernel oil) are preferably formed at a temperature of 70 to 100 °C, such as 80 to 90 °C.

In the invention, the oil is contacted with a natural adsorbent. Contacting the oil with the adsorbent may be...
Surprisingly, it has been found that natural adsorbents are superior to other absorbents for the treatment of the oil. In particular, natural adsorbents are unexpectedly better at extending the life of the enzyme in an interesterification reaction using the treated oil. Without wishing to be bound by theory, it is believed that the natural adsorbents provide the optimum removal of contaminants that are detrimental to the enzyme as well as causing the appropriate adjustment of the pH without excessive soap formation.

Natural adsorbents are generally minerals occurring in nature that have not been chemically modified or treated, for example by activation with acid or alkali. Natural adsorbents that are used in the invention are clays that have an intergrowth of two or more materials. More preferably, the natural adsorbents are based on an intergrowth of hormite and smectite minerals. Smectite clays include clays such as montmorillonite and bentonite. They have a layered or plate-like structure and are characterized by substitutions of metal ions within their structure, and are therefore electrically unbalanced. Hormite or attapulgite is a magnesium aluminium silicate clay of very fine particle size with a chain instead of a sheet structure.

Natural adsorbents that comprise an intergrowth of hormite and smectite minerals may be intermediate in structure between that of bentonite and attapulgite, with lamellae and tubules forming a three dimensional, porous network.

The natural adsorbent is preferably contacted with the oil in an amount of from 0.05 to 5.0 % by weight of the oil. More preferably, the adsorbent is contacted with the oil at a level of from 0.1 to 2 % by weight of the oil, such as from 0.2 to 0.8 % by weight. Typically, the adsorbent is added to the oil, more preferably with stirring.

Preferably, the adsorbent is contacted with the oil at a temperature of from 70 to 100 °C, such as 80 to 90 °C.

The adsorbent is preferably contacted with the oil at a reduced pressure, such as a pressure of less than 500 mbar, more preferably less than 250 mbar, for example 10 to 200 mbar.

Most preferably, the adsorbent is contacted with the oil at a temperature of from 70 to 100°C, such as 80 to 90°C and at a reduced pressure, such as a pressure of less than 500 mbar, more preferably less than 250 mbar, for example 10 to 200 mbar.

The adsorbent is preferably contacted with the oil for a time of from 5 minutes to 2 hours, more preferably from 10 minutes to 1 hour.

It has been found to be advantageous to treat the oil with the adsorbent in the presence of water. It is believed that the presence of water assists the removal of unwanted compounds, such as free fatty acids, from the oil, as well as allowing the oil to reach the desired pH range of from 6 to 8.

The pH is the pH of a water extract of the oil. The pH can be determined by AOCS Official Method G 7-56.

The amount of water that is used in the invention is not critical, provided that it is sufficient to achieve the pH of from 6 to 8. Typically, water is present in an amount of at least 0.10% by weight of the oil. Generally, the amount of water used in the invention will not exceed about 1 % by weight of the oil.

Preferably, water is added to the oil, prior to contacting the oil with the natural adsorbent, in an amount of from 0.01 to 0.5 % by weight of the oil, such as from 0.05 to 0.25 % by weight of the oil, for example from 0.10 to 0.20 % by weight of the oil. It will be appreciated, however, that the total water content may be higher than the amount of water that is added due to any water that is present in the oil and any water that is initially present in the adsorbent. Normally, the water will be dissolved and/or dispersed in the oil and/or associated with the adsorbent.

Separation of the oil is carried out by methods that will be known to those skilled in the art. For example, the adsorbent may be separated from the oil by filtration and this is preferred, particularly when the adsorbent is added to the oil. A filter of less than 5 microns, such as a 1 micron filter, is suitably used. Alternatively, the oil may be passed through a column or otherwise brought into contact with a body of the adsorbent and so may be separated simply by flowing out of the column or passing through or over the body of adsorbent.

Typically, the oil is dried during treatment with the adsorbent (for example by carrying out the contacting step at a reduced pressure below atmospheric pressure) and/or after being separated from the adsorbent.

Preferably, the treated oil is dried before or after being separated from the adsorbent. Drying may be carried out by methods that are well known to those skilled in the art. Preferably, the oil is dried under vacuum at a pressure of less than 500 mbar, such as from 1 to 200 mbar.

The invention has the advantage that the pH of the oil can be adjusted without the addition of a base that would form soaps (i.e., salts of fatty acids) from the glycerides in the oil. Preferably, the treated oil comprises less than 1 % by weight of soaps, such as less than 0.8 %, even more preferably less than 0.5 %, such as less than 0.1 % of soaps by weight of the oil. Soaps have an adverse effect on the taste of the oil and downstream products.

Treatment of the vegetable oil is preferably a pretreatment. The term "pretreatment" is well-known to those skilled in the art. Pretreatment is typically a treatment of the oil that takes place before further industrial processing, such as by chemical conversion. The pretreatment is preferably a purification of the oil prior to an enzyme-catalysed interes-
terification.

[0039] The oil that is treated according to the method of the invention is preferably used in the process of the invention for interesterifying a vegetable oil, which comprises treating the vegetable oil according to the method of the invention and reacting the vegetable oil in the presence of an enzymatic catalyst for interesterification.

[0040] The enzymatic catalyst is preferably a lipase. The lipase may be selective, for example for the 1 and 3 positions on the triglyceride, or it may have no selectivity between the 1, 2 and 3 positions of the triglyceride.

[0041] The lipase causes the fatty acid residues on the triglyceride to be more evenly distributed between the 1 and 3 (if it is selective for those positions) or the 1, 2 and 3 positions of the triglyceride. Preferably, the fatty acid residues are randomised during the interesterification reaction.

[0042] Lipases are commercially available. The most preferred lipase for use in the invention is a lipase from Thermomyces lanuginosus.

[0043] Preferably, the enzymatic catalyst is immobilised on a support.

[0044] A suitable lipase from Thermomyces lanuginosus immobilised on a support is available as Lipozyme TL IM from Novozymes A/S (Denmark).

[0045] It has been found that treatment of the oil according to the invention can increase the productivity of the catalyst in the interesterification reaction. Preferably, the productivity of the catalyst in the interesterification reaction is at least 1500 kg of oil per kg of catalyst, more preferably at least 1700 kg of oil per kg of catalyst, such as from 1800 to 2500 kg of oil per kg of catalyst.

[0046] The interesterification reaction may be carried out by methods that will be known to those skilled in the art. For example, the reaction may be conducted using a continuous process by, for example, passing the treated oil through a packed column containing the enzymatic catalyst. In a preferred embodiment, the oil is pumped through the column with a flow-rate of from 1 to 10 kg oil/kg enzyme/hr.

[0047] The interesterification reaction is preferably conducted at a temperature above 30°C, such as from 40 to 90°C. Preferably, the interesterification reaction is conducted at a temperature of from 60 to 80°C, such as about 70°C.

[0048] The product of the interesterification reaction may be used to produce a hardstock for a margarine or spread. Preferably, the hardstock is produced by fractionating the interesterified oil.

[0049] The hardstock itself is typically obtained from the product of the interesterification reaction as a stearin (i.e., higher melting fraction) that is produced by fractionation. Fractionation can be solvent fraction or dry fractionation. Dry fractionation is preferred.

[0050] The hardstock preferably comprises less than 15 %, more preferably less than 10 % unsaturated fatty acids based on the weight of total fatty acid residues.

[0051] A margarine fat blend is produced from the hardstock for use in the margarine or spread. The fat blend preferably comprises 80 to 95 % by weight liquid oil and 5 to 20 % by weight of the hardstock. Preferred liquid oils are low erucic acid rapeseed oil, soybean oil, sunflower oil, safflower oil, linseed oil, high oleic acid residue containing varieties of such oils, groundnut oil, olive oil, and mixtures thereof.

[0052] The margarine or spread is produced from the fat blend and comprises an aqueous phase and an oil phase consisting of the present margarine fat blend. The oil phase may comprise, in addition to the margarine fat blend, additives that are commonly used in such products, such as, for example, emulsifiers, flavours, colorants and vitamins. Similarly the aqueous phase may comprise, apart from water, milk ingredients, flavour, preservatives, structuring and gelling agents, for example. The margarine or spread preferably comprises 10 to 85 % by weight oil phase and 90 to 15 % by weight aqueous phase.

[0053] The following non-limiting examples illustrate the invention and do not limit its scope in any way. In the examples and throughout this specification, all percentages, parts and ratios are by weight unless indicated otherwise.

**Examples**

[0054] In the examples, reference is made to the attached drawing in which:

Figure 1 shows the experimental set-up for carrying out the process of Example 1.

**Example 1**

**Pre-treatment**

[0055] Hard palm fraction (palm oil stearin - POs) is blended with palm kernel oil (PK) and the oil blend is heated to 80-90°C. After this, 0.15% (by wt of the oil blend) demineralised water is added and the obtained mixture is stirred at an average speed and atmospheric pressure for 15 minutes. After this, 0.5% (by wt of the oil blend) of natural bleaching earth is added and the mixture is stirred for an additional 40 minutes at average speed and a reduced pressure of 100 mbar.
After this, the vacuum is released and the oil blend is filtered through a 1 μm filter.

**Enzymatic interesterification**

Enzymatic interesterification is conducted using a continuous process (see Figure 1) in which the feed stock is pumped through a packed column containing enzyme Lipozyme TL IM. The temperature of the feed stock and the packed bed reactor is set at 70°C. After this, the oil is pumped from tank 1 via line 4 through the column 2 with a flow-rate of 4 kg oil/kg enzyme/hr. The interesterified product exits the column via line 5 and is collected in a sample collector 3. The reaction progress is monitored by taking samples at regular time intervals and measuring the carbon number of the composition. The conversion is calculated based on these carbon numbers (see below).

**Calculation of conversion and activity**

When the POs/PK blend is interesterified, the following equation is used to calculate the conversion:

\[
X = \frac{[C_{44} + C_{46}]_{\text{prod}} - [C_{44} + C_{46}]_{\text{in}}}{[C_{44} + C_{46}]_{\text{in}} - [C_{44} + C_{46}]_{\text{out}}}
\]

The activity (k) is calculated by using the following equation (where \(F\) = flow and \(W\) = weight):

\[
Act = -\ln(1 - X) \times \frac{F}{W}
\]

When \(\ln k\) is plotted against time, a linear correlation is obtained. Rate of deactivation can be obtained by the slope of this linear correlation:

\[
Ln k = Ln k_0 - k_d \times t \quad \Rightarrow \quad Ln \left(\frac{k}{k_0}\right) = -k_d \times t \quad \Rightarrow \quad t_{1/2} = \frac{Ln 2}{k_d}
\]

The productivity is calculated using the following equation (at \(t = 2.5 \times t_{1/2}\)):

\[
Productivity = \frac{k_0 \times \left[e^{-k_d \times t_{1/2}} - 1\right]}{k_d \times \ln[1 - X]}
\]

**Examples 2 to 4 - Comparative**

**Example 2**

Example 1 was repeated but the feed stock was not pre-treated with bleaching earth.

**Example 3 - Comparative**

Example 1 was repeated but the feed stock was pre-treated with an acid-activated (i.e, non-natural) bleaching earth.

**Example 4 - Comparative**

Example 1 was repeated but the feed stock was pre-treated with silica.
Examples 1 to 4 - Results

[0065] The following results were obtained for the effect of the pretreatment on the performance of the lipase:

<table>
<thead>
<tr>
<th></th>
<th>ln k at 240 hours</th>
<th>ln k at 600 hours</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example 1</td>
<td>1.8</td>
<td>0.9</td>
</tr>
<tr>
<td>Example 2</td>
<td>1.5</td>
<td>0</td>
</tr>
<tr>
<td>Example 3</td>
<td>1.5</td>
<td>0</td>
</tr>
<tr>
<td>Example 4</td>
<td>1.4</td>
<td>0</td>
</tr>
</tbody>
</table>

[0066] Example 1 was the best pretreatment for prolonging the performance of the lipase, having the highest enzyme activity after 240 hours reaction and retaining activity at 600 hours.

Claims

1. A process for interesterifying a vegetable oil, which comprises treating the vegetable oil by contacting the vegetable oil with a natural adsorbent to give a pH in the range of from 6 to 8, separating the oil from the adsorbent and reacting the treated oil in the presence of an enzymatic catalyst for interesterification, where the natural adsorbent is a clay having an intergrowth of two or more materials.

2. Process as claimed in Claim 1, wherein the oil is contacted with the adsorbent in the presence of water.

3. Process as claimed in Claim 2, wherein water is added to the oil before the contacting step in an amount of from 0.01 to 0.5 % by weight of the oil.

4. Process as claimed in any one of the preceding claims, wherein the oil is dried during treatment with the adsorbent and/or after being separated from the adsorbent.

5. Process as claimed in any one of Claims 1 to 4, wherein the treated oil comprises less than 1 % by weight of soaps.

6. Process as claimed in any one of Claims 1 to 5, wherein the enzymatic catalyst is immobilised on a support.

7. Process as claimed in any one of Claims 1 to 6, wherein the enzymatic catalyst is a lipase.

8. Process as claimed in any one of Claims 1 to 7, wherein the enzymatic catalyst is a lipase from *Thermomyces lanuginosus*.

9. Process as claimed in any one of Claims 1 to 8, wherein the oil comprises one or more oil(s) derived from palm.

10. Process or method as claimed in Claim 9, wherein the oil comprises palm oil stearin and palm kernel oil.

11. Process as claimed in any one of Claims 1 to 10, wherein the productivity of the catalyst is at least 1500 kg of oil per kg of catalyst.

12. A method of increasing the productivity of an enzyme in the process for interesterifying a vegetable oil according to claim 1.

13. Method as claimed in Claim 12, wherein the oil is treated in the presence of water.

14. A method of producing a hardstock for a margarine, which comprises interesterifying a vegetable oil according to the process of any one of Claims 1 to 11.
Patentansprüche

1. Verfahren zur Umesterung eines pflanzlichen Öls, das das Behandeln des pflanzlichen Öls mit einem natürlichen Adsorptionsmittel, wobei ein pH-Wert im Bereich von 6 bis 8 erhalten wird, Abtrennen des Öls von dem Adsorptionsmittel und Umsetzen des behandelten Öls in Gegenwart eines enzymatischen Katalysators zur Umesterung umfasst, wobei das natürliche Adsorptionsmittel ein Ton ist, der ein Wachsen von zwei oder mehr Materialien aufweist.

2. Verfahren nach Anspruch 1, wobei das Öl mit dem Adsorptionsmittel in Gegenwart von Wasser in Kontakt gebracht wird.

3. Verfahren nach Anspruch 2, wobei Wasser dem Öl vor der Stufe des Inkontaktbringens in einer Menge von 0,01 bis 0,5 %, bezogen auf das Gewicht des Öls, zugesetzt wird.

5. Verfahren nach einem der Ansprüche 1 bis 4, wobei das behandelte Öl weniger als 1 Gew.-% an Seifen umfasst.

6. Verfahren nach einem der Ansprüche 1 bis 5, wobei der enzymatische Katalysator auf einem Träger immobilisiert ist.

7. Verfahren nach einem der Ansprüche 1 bis 6, wobei der enzymatische Katalysator eine Lipase ist.

8. Verfahren nach einem der Ansprüche 1 bis 7, wobei der enzymatische Katalysator eine Lipase von Thermomyces lanuginosus ist.

9. Verfahren nach einem der Ansprüche 1 bis 8, wobei das Öl ein oder mehrere Öle umfasst, die von Palmen stammen.

10. Verfahren oder Methode nach Anspruch 9, wobei das Öl Palmölstearin und Palmkernöl umfasst.

11. Verfahren nach einem der Ansprüche 1 bis 10, wobei die Produktivität des Katalysators mindestens 1500 kg Öl pro kg Katalysator beträgt.

14. Methode zur Herstellung eines Hardstock für eine Margarine, wobei die Methode die Umesterung eines pflanzlichen Öls nach dem Verfahren von einem der Ansprüche 1 bis 11 umfasst.

Revendications

1. Procédé d’interétérification d’une huile végétale, qui comprend le traitement de l’huile végétale par mise en contact de l’huile végétale avec un adsorbant naturel pour donner un pH compris dans la plage allant de 6 à 8, la séparation de l’huile de l’adsorbant et la réaction de l’huile traitée en présence d’un catalyseur enzymatique pour l’interéstérisation, dans lequel l’adsorbant naturel est une argile ayant une intercroissance de deux matériaux ou plus.

2. Procédé selon la revendication 1, dans lequel l’huile est mise en contact avec l’adsorbant en présence d’eau.

3. Procédé selon la revendication 2, dans lequel l’eau est ajoutée à l’huile avant l’étape de mise en contact en une quantité de 0,01 à 0,5 % en poids de l’huile.

4. Procédé selon l’une quelconque des revendications précédentes, dans lequel l’huile est séchée pendant le traitement avec l’adsorbant et/ou après avoir été séparée de l’adsorbant.

5. Procédé selon l’une quelconque des revendications 1 à 4, dans lequel l’huile traitée comprend moins de 1 % en
poids de savons.

6. Procédé selon l’une quelconque des revendications 1 à 5, dans lequel le catalyseur enzymatique est immobilisé sur un support.

7. Procédé selon l’une quelconque des revendications 1 à 6, dans lequel le catalyseur enzymatique est une lipase.

8. Procédé selon l’une quelconque des revendications 1 à 7, dans lequel le catalyseur enzymatique est une lipase de *Thermomyces lanuginosus*.

9. Procédé selon l’une quelconque des revendications 1 à 8, dans lequel l’huile comprend une ou plusieurs huiles dérivées du palmier.

10. Procédé selon la revendication 9, dans lequel l’huile comprend de la stéarine d’huile de palme et de l’huile de palmiste.

11. Procédé selon l’une quelconque des revendications 1 à 10, dans lequel la productivité du catalyseur est d’au moins 1500 kg d’huile par kg de catalyseur.

12. Procédé d’augmentation de la productivité d’une enzyme dans le procédé d’interestérisation d’une huile végétale selon la revendication 1.

13. Procédé selon la revendication 12, dans lequel l’huile est traitée en présence d’eau.

14. Procédé de production d’une matière grasse solide pour une margarine, qui comprend l’interestérisation d’une huile végétale selon le procédé de l’une quelconque des revendications 1 à 11.
