Note: Within nine months of the publication of the mention of the grant of the European patent in the European Patent Bulletin, any person may give notice to the European Patent Office of opposition to that patent, in accordance with the Implementing Regulations. Notice of opposition shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

Field of Technology

[0001] The present disclosure relates generally to communication networks and, more particularly, to a physical layer preamble format for transmissions in a multiple input, multiple output (MIMO) communications system.

Description of the Related Art

[0002] The background description provided herein is for the purpose of generally presenting the context of the disclosure. Work of the presently named inventor, to the extent it may be described in this background section, as well as aspects of the description that may not otherwise qualify as prior art at the time of filing, are neither expressly nor impliedly admitted as prior art against the disclosure. Work of the presently named inventor, to the extent it may be described in this background section, as well as aspects of the description that may not otherwise qualify as prior art at the time of filing, are neither expressly nor impliedly admitted as prior art against the disclosure.

[0003] Wireless local area networks (WLANs) have evolved rapidly over the past decade. Development of WLAN standards such as the Institute for Electrical and Electronics Engineers (IEEE) 802.11a, 802.11b, 802.11g, and 802.11n Standards has improved single-user peak data throughput. For example, the IEEE 802.11b Standard specifies a single-user peak throughput of 11 megabits per second (Mbps), the IEEE 802.11a and 802.11g Standards specify a single-user peak throughput of 54 Mbps, and the IEEE 802.11n Standard specifies a single-user peak throughput of 600 Mbps. Work has begun on a new standard, IEEE 802.11ac, that promises to provide even greater throughput.

Summary of the Disclosure

[0005] In one embodiment, a method for generating a preamble of a data unit for transmission via a multiple input, multiple output (MIMO) communication channel includes generating a first field of the preamble that provides a plurality of indicators to a plurality of receivers. Each one of the plurality of indicators indicates a set of a plurality of training sequences. The method also includes determining that a first set of the plurality of training sequences corresponds to transmission of the data unit to a corresponding one of a plurality of receivers. The method further includes utilizing the first set of the plurality of training sequences to generate an estimate of at least a portion of the MIMO communication channel.

[0006] In another embodiment, an apparatus includes a physical layer (PHY) unit configured to generate a preamble of a data unit for transmission via a MIMO communication channel. The first field of the preamble provides a plurality of indicators to a plurality of receivers.

**Detailed Description**

[0011] Fig. 1 is a block diagram of an example wireless local area network (WLAN) 10, according to an embodiment. The WLAN 10 supports downlink (DL) multiuser (MU) multiple-input and multiple-output (MIMO) communication between an access point (AP) and a plurality of client stations. Additionally, the WLAN 10 supports DL single-user (SU) communication between the AP and each of a plurality of client stations. The AP 14 includes a host processor 15 coupled to a network interface 16. The network interface 16 includes a medium access control (MAC) unit 18 and a physical layer (PHY) unit 20. The PHY unit 20 includes a plurality of transceivers 21, and the transceivers 21 are coupled to a plurality of antennas 24. Although three transceivers 21 and three antennas 24 are illustrated in Fig. 1, the AP 14 can include different numbers (e.g., 1, 2, 4, 5, etc.) of transceivers 21 and antennas 24 in other embodiments. In one embodiment, the MAC unit 18 and the PHY unit 20 are configured to operate according to a first communication protocol (e.g., the IEEE 802.11ac Standard, now in the process of being standardized). In another embodiment, the MAC unit 18 and the PHY unit 20 are also configured to operate according to a second communication protocol (e.g., the IEEE 802.11n Standard, the IEEE 802.11a Standard, the IEEE 802.11g Standard, etc.). The first communication protocol is referred to herein as a high throughput (VHT) protocol, and the second communication protocol is referred to herein as a legacy protocol.

[0012] The WLAN 10 includes a plurality of client stations 25. Although four client stations 25 are illustrated in Fig. 1, the WLAN 10 includes different numbers (e.g., 1, 2, 3, 5, 6, etc.) of client stations 25 in various scenarios and embodiments. At least one of the client stations 25 (e.g., client station 25-1) is configured to operate at least according to the VHT protocol. The WLAN 10 also includes a client station 40 that is not configured to operate according to the VHT protocol but is configured to operate according to the legacy protocol, in some embodiments. Such a client station 40 is referred to herein as a "legacy client station". In some embodiments, the WLAN 10 includes more than one legacy client station. In other em-
bodiments, the WLAN 10 includes no legacy client stations.

[0013] The client station 25-1 includes a host processor 26 coupled to a network interface 27. The network interface 27 includes a MAC unit 28 and a PHY unit 29. The PHY unit 29 includes a plurality of transceivers 30, and the transceivers 30 are coupled to a plurality of antennas 34. Although three transceivers 30 and three antennas 34 are illustrated in Fig. 1, the client station 25-1 includes different numbers (e.g., 1, 2, 4, 5, etc.) of transceivers 30 and antennas 34 in other embodiments.

[0014] In an embodiment, one or more of the client stations 25-2, 25-3, and 25-4 have a structure the same as or similar to the client station 25-1. In these embodiments, the client stations 25 structured the same as or similar to the client station 25-1 have the same or a different number of transceivers and antennas. For example, the client station 25-2 has only two transceivers and two antennas, according to an embodiment.

[0015] In various embodiments, the PHY unit 20 of the AP 14 is configured to generate data units conforming to the VHT protocol and having formats described hereinafter. The transceiver(s) 21 is/are configured to transmit the generated data units via the antenna(s) 24. Similarly, the transceiver(s) 21 is/are configured to receive data units conforming to the VHT protocol via the antenna(s) 24. The PHY unit 20 of the AP 14 is configured to process received data units conforming to the VHT protocol and having formats described hereinafter.

[0016] In various embodiments, the PHY unit 29 of the client station 25-1 is configured to generate data units conforming to the VHT protocol and having formats described hereinafter. The transceiver(s) 30 is/are configured to transmit the generated data units via the antenna(s) 34. Similarly, the transceiver(s) 30 is/are configured to receive data units conforming to the VHT protocol via the antenna(s) 34. The PHY unit 29 of the client station 25-1 is configured to process received data units conforming to the VHT protocol and having formats described hereinafter.

[0017] Fig. 2 is a diagram of a data unit 100 that the PHY unit 20 of the AP 14 is configured to transmit as data units to the client station 25-1. The PHY unit 20 of the AP 14 is configured to transmit the generated data units via the antenna(s) 24. Similarly, the transceiver(s) 21 is/are configured to receive data units conforming to the VHT protocol via the antenna(s) 24. The PHY unit 20 of the AP 14 is configured to process received data units conforming to the VHT protocol and having formats described hereinafter.

[0018] The data unit 100 includes a preamble having four legacy short training fields (L-STFs) 105; four legacy long training fields (L-LTFS) 110; four legacy signal fields (L-SIGs) 115; four very high throughput short training signal fields (VHT-SIG1s) 120; a very high throughput short training field (VHT-STF) 125; N very high throughput long training fields (VHT-LTFs) 130, where N is an integer; and a second very high throughput signal field (VHT-SIG2) 135. The data unit 100 also includes a very high throughput data portion (VHT-DATA) 140. The L-STFs 105, the L-LTFs 110, and the L-SIGs 115 form a legacy portion. The VHT-STF 125, the VHT-LTFs 130, the VHT-SIG2 135, and the VHT-DATA 140 form a very high throughput (VHT) portion.

[0019] Each of the L-STFs 105, each of the L-LTFs 110, each of the L-SIGs 115, and each of the VHT-SIG1s 120 occupy a 20 MHz band, in one embodiment. In the present disclosure, several example data units, including the data unit 100, having an 80 MHz contiguous bandwidth are described for the purposes of illustrating embodiments of frame formats, but these frame format embodiments and other embodiments are applicable to other suitable bandwidths (including noncontiguous bandwidths). For instance, although the preamble of the data unit 100 includes four of each of the L-STFs 105, the L-LTFs 110, the L-SIGs 115, and the VHT-SIG1s 120, in other embodiments in which an OFDM data unit occupies a cumulative bandwidth other than 80 MHz, such as 20 MHz, 40 MHz, 120 MHz, 160 MHz, etc., a different suitable number of the L-STFs 105, the L-LTFs 110, the L-SIGs 115, and the VHT-SIG1s 120 are utilized accordingly. For example, for an OFDM data unit occupying a 20 MHz cumulative bandwidth, the data unit includes one of each of the L-STFs 105, the L-LTFs 110, the L-SIGs 115, and the VHT-SIG1s 120; a 40 MHz bandwidth OFDM data unit includes two of each of the fields 105, 110, 115, and 120; a 120 MHz bandwidth OFDM data unit includes six of each of the fields 105, 110, 115, and 120; and a 160 MHz bandwidth OFDM data unit includes eight of each of the fields 105, 110, 115, and 120, according to some embodiments.

[0020] In the example data unit 100, each of the VHT-STF 125, the VHT-LTFs 130, the VHT-SIG2 135, and the VHT-DATA 140 occupy the entire 80 MHz cumulative bandwidth of the data unit 100. Similarly, in the case of an OFDM data unit conforming to the first VHT protocol and occupying a cumulative bandwidth such as 20 MHz, 40 MHz, 120 MHz, or 160 MHz, each of the VHT-STF 125, the VHT-LTFs 130, the VHT-SIG2 135, and the VHT-DATA 140 occupy the corresponding entire cumulative bandwidth of the data unit, in some embodiments.

[0021] In some embodiments, the 80 MHz band of the data unit 100 is not contiguous, but includes two or more smaller bands, such as two 40 MHz bands, separated in frequency. Similarly, for other OFDM data units having different cumulative bandwidths, such as a 160 MHz cumulative bandwidth, in some embodiments the band is not contiguous in frequency. Thus, for example, the L-STFs 105, the L-LTFs 110, the L-SIGs 115, and the VHT-SIG1s 120 occupy two or more bands that are separated from each other in frequency, and adjacent bands are separated in frequency by at least one MHz, at least five
According to an embodiment, each of the L-STFs 105 and each of the L-LTFs 110 have a format as specified in a legacy protocol such as the IEEE 802.11 a Standard and/or the IEEE 802.11n Standard. In an embodiment, each of the L-SIGs 115 has a format at least substantially as specified in legacy protocol (e.g., the IEEE 802.11a Standard and/or the IEEE 802.11n Standard). The length and rate subfields in the L-SIGs 115 is set to indicate the duration T corresponding to the remainder of the data unit 100 after the legacy portion. This permits client stations that are not configured according to the VHT protocol to determine an end of the data unit 100 for carrier sense multiple access/collision avoidance (CSMA/CA) purposes, for example. For instance, a legacy client station configured according to the IEEE 802.11a Standard will detect a data error from the VHT-SIG1s 120, according to the receiver state machine specified in the IEEE 802.11a Standard. In this situation, the legacy client station waits until the energy of the data unit 100 drops out before switching to CCA idle mode.

In the data unit 100, the frequency domain symbols of the legacy portion are repeated over four 20 MHz subbands of the 80 MHz band. Legacy client stations that are configured according to the IEEE 802.11a Standard and/or the IEEE 802.11n Standard with 20 MHz bandwidth will recognize a legacy IEEE 802.11a Standard preamble in any of the 20 MHz subbands. In some embodiments, the modulations of the different 20 MHz subband signals are rotated by different angles. In one example, a first subband is rotated 0 degrees, a second subband is rotated 90 degrees, a third subband is rotated 180 degrees, and a fourth subband is rotated 270 degrees, in an embodiment. In other examples, different suitable rotations are utilized. As just one example, a first subband is rotated 45 degrees, a second subband is rotated -90 degrees, a third subband is rotated 90 degrees, a fourth subband is rotated -45 degrees, and a fourth subband is rotated -90 degrees, in an embodiment. In an embodiment, the same rotations utilized in the legacy portion (if present) are utilized for the VHT-SIG1s 120. In at least some examples, the VHT-SIG1s 120 are collectively referred to as a single first very high throughput signal field (VHT-SIG1) 120.

As shown in Fig. 2, the VHT-SIG2 135 are included after one or more of the VHT-LTFs 130 and are spatially mapped the same way as one of the one or more VHT-LTFs 130. For example, the VHT-SIG2 135 are spatially mapped by a vector $Q_{1}$, where $Q$ is an antenna map or spatial mapping matrix that maps spatial streams, or space-time streams if space-time encoding is utilized, to transmit antennas, and $P_{1}$ is a first column in a spatial stream mapping matrix $P$, which is a Hadamard matrix in which each element of $P$ is +1 or -1. In an embodiment, in another embodiment, some elements of $P$ are integers other than +1 or -1. In an embodiment, $P_{1}$ corresponds to a first spatial stream.

More generally, as each VHT-LTF is generated, a separate column of the matrix $P$ is used to map the values to spatial streams. For example, the first column of the matrix $P_{1}$, i.e., $P_{1}$, is applied to the signal VHT-LTF1 130-1, the second column of the matrix $P_{2}$, i.e., $P_{2}$, is applied to the signal VHT-LTF2, etc., in an embodiment. Thus, a client station 25 may use the channel estimation from the VHT-LTF1 to decode the VHT-SIG2 135, in an embodiment. According to another embodiment, the VHT-SIG2 is spatially mapped by a vector $Q_{N}$ so that a client station 25 may use the channel estimation from the VHT-LTFN 130-N to decode the VHT-SIG2 135, in another embodiment. Various other suitable embodiments of the data unit 100, including various suitable positions of the VHT-SIG2 135, are described in U.S. Patent Application No. 12/758,603, entitled "Physical Layer Frame Format for WLAN," filed on April 12, 2010.

By placing the VHT-SIG2 135 after one or more of the VHT-LTFs 130 and spatially mapping the VHT-SIG2 135 in the foregoing manner, the PHY unit 20, the transceivers 21, and the antennas 24 may implement space-division multiple access (SDMA) downlink transmissions which differentiate the VHT-SIG2 135 for different users by beam-steering, while the L-STFs 105, the L-LTFs 110, the L-SIGs 115, and the VHT-SIG1s 120 remain unsteered (or "omnidirectional" or "pseudo-omnidirectional"; the terms "unsteered" and "omnidirectional" as used herein are intended to also encompass the term "pseudo-omnidirectional") and contain PHY information that is common to each of the client stations 25. On the other hand, the VHT-SIG2 135 includes different data for different clients 25 that are simultaneously transmitted, via the antennas 24, over different spatial channels to carry different (or "user-specific") content to each of the client stations 25. Accordingly, the VHT-SIG2 135 illustrated in Fig. 2 represents different information being transmitted to different clients via different spatial streams, in some embodiments. For ease of explanation,
the VHT-SIG2 135, and other steered portions of the various data units disclosed herein, may at times be illustrated and/or described herein in this manner. However, it will be understood that the VHT-SIG2 135 and other such steered portions may include different information being transmitted to different clients via different spatial streams, in some embodiments as discussed above, for example.

[0028] The VHT-SIG1 120 comprises two OFDM symbols, according to an embodiment. The VHT-SIG2 135 comprises one OFDM symbol, according to an embodiment.

[0029] The preamble of the data unit 100 allows each client station 25 to estimate at least a portion of the signal channel from the AP 14 to the client station 25, and based on this estimation, equalize the channel to decode data (e.g., within the VHT-DATA 140) transmitted from the AP 14 to the client station 25 (e.g., the client station 25-1). For example, the client station 25-1 determines a number of channel dimensions from the AP 14 to the client station 25-1 and estimates each of the channel dimensions using one or more of the VHT-LTFs 130, in an embodiment. The data unit 100 includes a number of spatial streams, or space-time streams if space-time encoding is utilized, transmitted from the AP 14 to each of the client stations 25, and the client station 25-1 may further determine which particular spatial streams or space-time streams transmitted from the AP 14 include information for the client station 25-1. In order to allow the client station 25-1 to estimate its corresponding number of channel dimensions, the AP 14 transmits a corresponding number of the VHT-LTFs 130 to the client station 25-1, in an embodiment.

[0030] In an embodiment, one or more of the VHT-LTFs 130 that are allocated to a particular client station 25 for channel estimation are not allocated to one or more of the other client stations 25 for channel estimation. According to an embodiment, the PHY unit 20 generates at least enough VHT-LTFs 130 to jointly train all of the client stations 25 to estimate the signal channels corresponding thereto. In an embodiment, the data unit 100 includes the number of spatial streams, or space-time streams if space-time encoding is utilized, transmitted from the AP 14 to each of the client stations 25. In an embodiment, when the VHT-LTFs 130 are resolvable, each client station 25 receives all of the VHT-LTFs 130 and uses the indication of the number of spatial or space-time streams to determine which ones of the VHT-LTFs 130 to use for its own channel estimation, in advance of receiving the VHT-LTFs 130. For example, in some embodiments one or more indications of the number of spatial/space-time streams corresponding to a particular client station 25 are included in the VHT-SIG2 135. The data unit 100 also or alternatively includes a suitable indication of the corresponding number of spatial/space-time streams in the VHT-SIG1 120, in an embodiment. Several examples of such an indication are described in detail below.

[0031] By making an advance determination of which ones of the VHT-LTFs 130 are needed for channel estimation, each client station 25 avoids buffering other ones of the VHT-LTFs 130 in memory that are not needed for channel estimation, in an embodiment. Such an advance determination also allows the client station 25 to begin channel estimation substantially contemporaneously with receipt of the VHT-LTFs 130, in an embodiment. For instance, if the beginning of channel estimation is delayed beyond receipt of the VHT-LTFs 130 corresponding to the spatial/space-time streams for the client station 25, the client station 25 may need to be able to rapidly perform channel estimation and determine an equalizer for the channel in time to accurately decode the data in the VHT-DATA 140. Such rapid channel estimation may create an undesirable processing load on the PHY unit 29, in some embodiments.

[0032] In some embodiments where the VHT-LTFs 130 are resolvable, each client station 25 also attempts to mitigate, or "whiten", interference resulting from the spatial/space-time streams sent to other ones of the client stations 25. Therefore, the data unit 100 enables each client station 25 to determine not only the number of spatial/space-time streams from the AP 14 to the client station 25, but also the numbers of spatial/space-time streams from the AP 14 to each other one of the client stations 25, in an embodiment. The data unit 100 also enables each client station 25 to determine which ones of the VHT-LTFs 130 each other client station 25 needs to use for channel estimation. Each client station 25 then uses the channel training information for the other client stations 25 to mitigate received interference from the spatial/space-time streams sent to each of the other client stations 25. In these embodiments as well, the data unit 100 advantageously allows each client station 25 to make an advance determination of which ones of the VHT-LTFs 130 to use for channel estimation, even though others of the VHT-LTFs 130 are used for interference mitigation or whitening.

[0033] Figs. 3A and 3B are diagrams of example bit allocations for the VHT-SIG1 120 and VHT-SIG2 135, respectively, according to an embodiment. The example bit allocations of Figs. 3A and 3B are used when the AP 14 is supporting downlink multiuser MIMO (DL-MUMIMO) communication, in an embodiment. As shown in Fig. 3A, the VHT-SIG1 120 includes a plurality of subfields 142. The plurality of subfields 142 includes a duration subfield 142-1, a bandwidth subfield 142-2, a short guard interval (SGI) subfield 142-3, a smoothing subfield 142-4, a space-time block coding (STBC) subfield 142-5, a multi-user (MU)/single-user (SU) subfield 142-6, a group ID subfield 142-7, a resolvable LTF subfield 142-8, a number of spatial streams (Nss) subfield 142-9, and an MU reserved subfield 142-10 which may be for implementing MU features developed in the future, etc. The VHT-SIG1 120 also includes one or more additional subfields which are collectively referred to as additional subfields 142-11. The additional subfields 142-11 include, for example, one or more of a cyclic redundancy check...
According to an embodiment, the MU/SU subfield 142-6 includes a single bit which is set to a logic “1” to indicate that the AP 14 is operating in MU mode. According to another embodiment, the single bit in the MU/SU subfield 142-6 is set to a logic “0” to indicate that the AP 14 is operating in MU mode. As further described below, the group ID subfield 142-7 indicates an MU group to which the data unit 100 is directed, in an embodiment.

In some other embodiments, the MU/SU subfield 142-6 is removed, and one of the possible bit sequences of the group ID subfield 142-7 is reserved for the purpose of indicating that the data unit 100 is an SU data unit. As just one example, every bit in the group ID subfield 142-7 is set to a logic “1” to indicate SU mode, in an embodiment. As just one further example, every bit in the group ID subfield 142-7 is set to a logic “0” to indicate SU mode, in an embodiment. In still further embodiments, one possible bit sequence of the group ID subfield 142-7 is used to indicate that the data unit 100 is a broadcast frame, in addition to or instead of using one possible bit sequence of the group ID subfield 142-7 to indicate that the data unit 100 is an SU data unit. In even further embodiments, the bit sequence of the group ID subfield 142-7 used to indicate that the data unit 100 is a broadcast frame is the same bit sequence which is used when the data unit 100 is an SU data unit. The bit sequence of the group ID subfield 142-7 which is used when the data unit 100 is an SU data unit is also used when the data unit 100 is an MU data unit but one or more of the client stations 25 have not been assigned to an MU group, according to an embodiment.

In MU mode, the STBC subfield 142-5 and the NsS subfield 142-9 provide indications of numbers of space-time streams for each of the client stations 25.

As will be recognized by one of ordinary skill in the art in light of the teaching and disclosure herein, the number of space-time streams corresponding to a client station 25 is a number of spatial streams transmitted to the client station 25 via the antennas 24 when STBC is not used. Accordingly, for purposes of the present disclosure, a spatial stream that is not encoded using STBC may at times be referred to herein as a space-time stream for ease of explanation. When spatial streams transmitted to a client station 25 are encoded using STBC, the number of space-time streams corresponding to the client station 25 are determined by the number of spatial streams corresponding to the client station 25 and by a particular space-time block code being used, such as an Alamouti code. For example, encoding a single spatial stream with an Alamouti code results in two space-time streams.

According to an embodiment, the STBC setting is the same for each of the client stations 25, and as such only a single bit is required in the STBC subfield 142-5 to indicate whether STBC is being used. As shown in Fig. 3A, the STBC subfield 142-5 includes one bit, which is, for example, set to “1” if STBC is being used and “0” if STBC is not being used, or vice versa. According to an embodiment, the number of spatial streams corresponding to each of the client stations 25 is different. Each of the client stations 25 determines its corresponding number of spatial streams using a unique index value assigned to that client station 25 using a management frame or control frame, such as a sounding frame.
by the group ID subfield 162, and further determines that its unique index value is the number two, i.e., that the indication of its own number of spatial streams will be the second indication within the Nss subfield 142-9 in order of receipt. Based on detection of the AIDs in the other AID subfields 164-1, 164-3, and 164-4, the second client station 25-2 also determines the unique index values assigned to the other client stations 25-1, 25-3, and 25-4. Of course, in the example group definition field 160, the AID of a particular client station, such as the client station 25-2, is included in any other suitable one of the AID subfields 164 (e.g., the subfield 164-1, the subfield 164-3, etc.), in some embodiments.

[0041] The AP 14 is configured to transmit a sounding frame including the group definition field 160 to each of the client stations 25. The sounding frame also is used to request an acknowledgement from each one of the client stations 25 of the user index value associated therewith, and to request channel measurement feedback, in an embodiment. The AP 14 determines the spatial mapping Q matrix for the client stations 25 by processing responsive feedback frames. The PHY unit 20 is configured to use the Q matrix to generate the VHT-SIG2 135, which the transceivers 21 and the antennas 24 transmits to the different client stations 25 simultaneously over a plurality of different spatial channels. Various example implementations of beam-steering of signal fields such as the VHT-SIG2 135 are described in U.S. Patent Application No. 12/750,636, entitled "Sounding and Steering Protocols for Wireless Communications," filed on March 30, 2010. Example implementations of beam-steering of signal fields such as the VHT-SIG2 135, including through the use of sounding frames, are also described in U.S. Patent Application No. 12/175,526, entitled "Access Point with Simultaneous Downlink Transmission of Independent Data for Multiple Client Stations," filed on July 18, 2008.

[0042] Fig. 5 is an example timing diagram that shows a sounding frame 170 being transmitted from the AP 14 to each of the client stations 25, according to an embodiment. For example, the AP 14 broadcasts the sounding frame 170 to the client stations 25. Alternatively, the AP 14 transmits multiple sounding frames to the client stations 25, where a different one of the sounding frames is transmitted to each one of the client stations 25. For ease of explanation, however, the disclosure herein will refer to the sounding frame 170 being transmitted to each of the client stations 25 (e.g., the client stations 25-1 and 25-2).

[0043] The sounding frame 170 includes a payload portion, which includes the group definition field 160, according to an embodiment. In another embodiment, the sounding frame 170 omits a payload portion, and the group definition field 160 is included in a PHY preamble portion. According to an embodiment, in response to the client station 25-1 receiving the sounding frame 170 and receiving and recording its associated user index value contained therein, the PHY unit 29 of the client station 25-1 generates a feedback frame 172 for transmission to the AP 14 during a first time slot. Similarly, in response to the client station 25-2 receiving the sounding frame 170 and receiving and recording its associated user index value contained therein, the PHY unit 29 of the client station 25-2 generates a feedback frame 174 for transmission to the AP 14 during a second time slot, and so on for any other ones of the client stations 25. Each of the feedback frames 172 and 174 includes a suitable acknowledgement that the corresponding one of the client stations 25 has received and recorded its associated user index value. Accordingly, upon receipt of the feedback frames 172 and 174, the AP 14 verifies that each of the client station 25-1 and the client station 25-2 correctly recorded its assigned user index value. The AP 14 also uses the feedback frames 172 and 174 to determine the spatial mapping Q matrix, as discussed above.

[0044] Other suitable implementations of sounding frames, non-sounding management frames, etc. are also used to assign a group identifier and associated unique index value to each of the client stations 25, in other embodiments. For example, the group definition field 160 is transmitted within a non-sounding management frame, according to an embodiment. As just one additional example, the AP 14 uses a non-sounding management frame to implement a "stand-alone" MAC or AID exchange, e.g., an association of MAC addresses or AIDs of the client stations 25 with group IDs and user index values without a request for channel measurement feedback, in an embodiment. In one embodiment, the MAC unit 18 generates at least part of the non-sounding management frame and/or the information therein. In another embodiment, the PHY unit 20 generates the non-sounding management frame. For example, a payload portion of the management frame associates a MAC address or AID of the client station 25-1 with a group ID and a first index value, such as the number one, according to an embodiment. The data portion further associates a MAC address or AID of the client station 25-2 with the same group ID and a second index value, a MAC address or AID of the client station 25-3 with the same group ID and a third index value, and a MAC address or AID of the client station 25-4 with the same group ID and a fourth index value, according to an embodiment.

[0045] In still another embodiment using a non-sounding management frame, the non-sounding management frame is a unicast frame that assigns multiple group IDs and associated unique index values for each group ID to a single client station 25. According to yet another embodiment, the non-sounding management frame is a multicast frame that is transmitted to an entire MU group. The multicast frame assigns multiple group IDs, and associated unique index values for each group ID, to one or more client stations 25 in the MU group to which the multicast frame is transmitted.

[0046] According to an embodiment, the unique index values assigned to the client stations 25 are refreshed each time the AP 14 transmits a sounding frame or other
management frame. According to another embodiment, the unique index values assigned to the client stations 25 are refreshed less frequently. For example, the unique index values are refreshed every second time the AP 14 transmits a sounding frame or other management frame, every third time, etc., according to other embodiments. The frequency with which the unique index values are refreshed depends on a degree and/or rate of change of the characteristics of the signal channels between the AP 14 and the client stations 25, according to an embodiment.

[0047] Once a client station 25 determines both that it is a member of a particular MU group and its unique index value within the particular MU group, the client station 25 determines, upon receipt of the group ID subfield 142-7, whether the group ID subfield 142-7 matches the group ID subfield 162 or an ID of any other MU group to which the client station 25 belongs. For example, the client station 25 is assigned to multiple MU groups using multiple group definition fields 160, or other suitable management frames or control frames, in some embodiments. If the client station 25 determines that the group ID subfield 142-7 matches the group ID subfield 162 or the group ID of any other MU group to which the client station 25 belongs, the client station 25 processes the entire VHT-SIG1 120. The client station 25 thereby determines its corresponding number of space-time streams. According to an embodiment, if the group ID subfield 142-7 does not match the group ID subfield 162 or the group ID of any other MU group to which the client station 25 belongs, the client station 25 determines that it is not a member of the MU group to which the data unit 100 is directed and disregards the remainder of the data unit 100. By disregarding the remainder of the data unit 100, the client station 25 conserves power by, for example, not attempting to receive and/or decode the remainder of the data unit 100.

[0048] According to an embodiment, one possible bit sequence of the group ID subfield 142-7 is reserved for the purpose of indicating that the data unit 100 is an SU data unit. Therefore, if the group ID subfield 142-7 does not match the group ID subfield 162 pertaining to a previous MU transmission, but the group ID 142-7 does match the reserved bit sequence, the client station 25 determines that the data unit 100 is an SU data unit, in some embodiments.

[0049] In order to indicate the number of spatial streams corresponding to each unique index value, and thereby indicate (in conjunction with the STBC subfield 142-5) a corresponding number of space-time streams, the Nss subfield 142-9 itself includes a plurality of subfields. Each one of the plurality of Nss sub-subfields includes information for one of each of the client stations 25. Fig. 6 is a diagram of the plurality of Nss sub-subfields showing that Nss subfield 142-9 is formed from four Nss sub-subfields 142-9-a, 142-9-b, 142-9-c, and 142-9-d, according to an embodiment. The Nss sub-subfields 142-9-a, 142-9-b, 142-9-c, and 142-9-d are labeled Nss1, Nss2, Nss3, and Nss4, respectively, and each includes an indication of the number of spatial streams allocated to the corresponding client, according to an embodiment. In the example of Fig. 3A, the Nss subfield 142-9 includes a total of eight bits, such that two bits are allocated to each of the Nss sub-subfields 142-9-a, 142-9-b, 142-9-c, and 142-9-d as shown in Fig. 6, in an embodiment. Each client station 25 each receives the entire Nss subfield 142-9, but determines which of the Nss sub-subfields 142-9-a, 142-9-b, 142-9-c, and 142-9-d corresponds to the client station 25 by using the unique index value assigned to the client station 25 (during the group definition process or other process of assigning a group ID and unique index value, as described above) in conjunction with prior knowledge of the number of bits in each of the Nss sub-subfields 142-9-a, 142-9-b, 142-9-c, and 142-9-d. In an embodiment where the client station 25 performs interference mitigation, the client station 25 also determines the number of space-time streams for the other client stations 25 using the STBC subfield 142-9 in conjunction with knowledge of the unique index values assigned to the other client stations 25.

[0050] When two bits are allocated to each of the Nss sub-subfields 142-9-a, 142-9-b, 142-9-c, and 142-9-d, the Nss subfield 142-9 indicates whether 0, 1, 2, or 3 spatial streams are allocated to each of the client stations 25-1, 25-2, 25-3, and 25-4 of the WLAN 10, according to an embodiment. Additionally, the Nss subfield 142-9 indicates another suitable range of numbers of spatial streams, in other embodiments. For example, the VHT-SIG2 135 indicates a modulation and coding scheme (MCS) for each of the client stations 25 using a sequence of bits for each client station 25, where one such sequence indicates that no data is being transmitted to the corresponding client station 25, in an embodiment. In this case, the two bits in each Nss sub-subfield are used to indicate whether 1, 2, 3, or 4 spatial streams are allocated to each of the client stations 25-1, 25-2, 25-3, and 25-4, according to an embodiment. In some other possible implementations of the VHT-SIG1 120, different numbers of bits are allocated to the Nss subfield 142-9. Additionally, the Nss subfield 142-9 indicates the numbers of spatial streams for more or less than four client stations 25, according to some embodiments. When the Nss subfield 142-9 indicates that zero space-time streams are allocated to any of the client stations 25, the corresponding client station or stations 25 disregards the remainder of the data unit 100, thereby saving power as described above.

[0051] The example bit allocation for VHT-SIG2 135 of Fig. 3B is implemented in conjunction with the example bit allocation shown in Fig. 3A, and/or with any other suitable bit allocation for the VHT-SIG1 120. The VHT-SIG2 135 includes a plurality of subfields 152. According to an embodiment, the plurality of subfields 152 includes an MCS subfield 152-1, a coding type subfield 152-2, a reserved subfield 152-3 (e.g., for implementing features developed in the future), a CRC subfield 152-4, and a
subfield 152-5 including tail bits. The MCS subfield 152-1 specifies a modulation and coding scheme (MCS) that the AP 14 uses in generating and transmitting the space-time streams corresponding to each client station 25. By transmitting the VHT-SIG2 135 over different spatial channels and, optionally, using beamsteering, the AP 14 utilizes the MCS subfield 152-1 and other ones of the subfields 152 to transmit user-specific information for each client station 25.

[0052] Accordingly, the data unit 100 allows the indications of the MCS for each client station 25 to be included within the VHT-SIG2 135, while advantageously providing complete indications of the numbers of space-time streams for each client station 25 in the VHT-SIG1 120 using the STBC subfield 142-5 and the Nss subfield 142-9. Each of the client stations 25 processes the STBC subfield 142-5 and the Nss subfield 142-9 before receiving the VHT-LTFs 130. Therefore, each client station 25 is enabled to process, without buffering, only those ones of the received VHT-LTFs 130 that the client station 25 needs to determine the equalizer for its own space-time streams, according to an embodiment. In other embodiments, the client station 25 processes VHT-LTFs 130 that correspond to other stations for interference mitigation purposes, for example.

[0053] The client stations 25 each determines which ones of the space-time streams, and which ones of the VHT-LTFs 130, to process based on the unique index values assigned by the AP 14. According to an embodiment, the client stations 25 use the unique index values in conjunction with knowledge of a spatial mapping Q matrix in order to determine which space-time streams and which ones of the VHT-LTFs 130 to process.

[0054] According to another embodiment, the Nss subfield 142-9 specifies an index value which in turn specifies an entry in a lookup table (LUT). The LUT has a plurality of entries, and each entry indicates numbers of spatial streams for one or more client stations 25. The LUT therefore specifies suitable combinations of numbers of spatial streams that are allocated to the various client stations 25. In the example of Fig. 3A, the Nss subfield 142-9 includes eight bits and therefore specifies any of 256 different index values corresponding to 256 entries in the LUT, according to an embodiment. Of course, other suitable indications of a number of space-time streams are utilized in other embodiments.

[0055] Figs. 7A and 7B are diagrams of example bit allocations for the VHT-SIG1 120 and the VHT-SIG2 135, according to an embodiment. The bit allocations of Figs. 7A and 7B are similar to those of Figs. 3A and 3B, except that the STBC subfield 142-5 is removed from the VHT-SIG1 120 and an STBC subfield 152-6 is included in the VHT-SIG2 135. Additionally, the Nss subfield 142-9 is replaced with an Nsts subfield 142-12, which indicates a number of space-time streams for each client station 25. In another embodiment, the Nsts subfield 142-12 indicates an index to a LUT having different combinations of space-time streams. The Nsts subfield 142-12 includes nine bits, according to the embodiment illustrated in Fig. 7A.

[0056] By indicating the number of space-time streams using the Nsts subfield 142-12, the STBC subfield 142-5 is not needed to determine the number of space-time streams for a particular client station 25. Because the PHY unit 20 is configured to generate different VHT-SIG2 135 data for simultaneous transmission to different client stations 25, including the STBC subfield 152-6, the VHT-SIG2 135 allows user-specific control of STBC settings. Therefore, in an embodiment, STBC may be used for the spatial streams corresponding to some of the client stations 25 but not for the spatial streams corresponding to other ones of the client stations 25.

[0057] In an embodiment, each client station 25 determines an equalizer for its space-time streams based on its number of space-time streams, and not based on the number of spatial streams corresponding to the client station 25. If the Nsts subfield 142-12 indicates, for example, that two space-time streams correspond to the client station 25, the same equalizer is determined regardless of whether STBC is not used and the number of spatial streams is two, or STBC is used and the number of spatial streams is one, according to an embodiment. If the STBC subfield 152-6 subsequently indicates that STBC is used, the client station 25 groups OFDM symbols together in pairs (e.g., one OFDM symbol from each space-time stream), for example, and performs STBC decoding after at least a portion of the equalization has been performed, according to an embodiment.

[0058] In some embodiments, use of the Nsts subfield 142-12 allows more bits in the VHT-SIG1 120 to be utilized for purposes other than indicating numbers of space-time streams. For example, the Nsts subfield 142-12 is implemented with eight or fewer bits, according to an embodiment. In such an embodiment, removing the STBC subfield 142-5 from the VHT-SIG1 120 results in fewer total bits in the VHT-SIG1 120 being used to indicate the numbers of space-time streams for the client stations 25 as compared to, for example, the bit allocation of Fig. 3A. In other embodiments, the Nsts subfield 142-12 or a similar subfield is included in the VHT-SIG1 120 along with the STBC subfield 142-5 or a similar subfield. Suitable alternatives to other embodiments of the data unit 100 and other data units, such as those embodiments described below, also include the Nsts subfield 142-12.

[0059] Fig. 8 is a diagram of still another example bit allocation for the VHT-SIG1 120 which is used when, for example, the L-SIGs 115 indicate the duration T of the data unit 100 after the legacy portion, in another embodiment. According to an embodiment, the rate subfield in the L-SIGs 115 is set to 6 Mbps, and the length subfield is set such that the rate and length subfields together indicate the duration T. The VHT-SIG1 120 therefore is implemented without the duration subfield 142-1, which thus frees twelve bits of the VHT-SIG1 120 for other uses, according to an embodiment. For example, as shown in...
Fig. 8, the STBC subfield 142-5 is implemented as a plurality of STBC sub-subfields 142-5-a, 142-5-b, 142-5-c, and 142-5-d, which are denoted STBC1, STBC2, STBC3, and STBC4, respectively. The STBC sub-subfields 142-5-a, 142-5-b, 142-5-c, and 142-5-d each corresponds to one of the client stations 25-1, 25-2, 25-3, and 25-4, according to an embodiment. Each of the STBC sub-subfields 142-5-a, 142-5-b, 142-5-c, and 142-5-d includes a single bit that indicates whether space-time streams for the corresponding client station 25 are encoded, using an Alamouti code for example, or whether STBC is not being used with the spatial streams for the corresponding client station 25, according to an embodiment. The example bit allocation of Fig. 8 therefore is used to indicate user-specific STBC settings in the VHT-SIG1 120 so that the STBC setting need not be the same for all of the client stations 25. According to an embodiment, the other excess bits in the example of Fig. 8, as compared to previous-discussed embodiments of the VHT-SIG1 120, are included in the MU reserved subfield 142-10. One of ordinary skill in the art will also recognize additional and/or alternative suitable uses for the excess bits in light of the teachings and disclosure herein.

According to various other embodiments, the AP 14 also operates in single-user (SU) mode, where the AP 14 supports downlink single-user wireless communication. The data unit 100 also is used to transmit information to a client station 25 in SU mode, in some embodiments. In SU mode, the VHT-SIG1 120 is implemented without some of the subfields 142 described above with respect to various embodiments in MU mode. According to some embodiments, the VHT-SIG2 135 is implemented without some of the subfields 152 in SU mode, or is removed altogether.

Figs. 9A and 9B are diagrams of example bit allocations for the VHT-SIG1 120 and VHT-SIG2 135, respectively, for SU mode. As shown in Fig. 9A, the VHT-SIG1 120 includes the duration subfield 142-1, the bandwidth subfield 142-2, the SGI subfield 142-3, the smoothing subfield 142-4, the MU/SU subfield 142-6, the MCS subfield 152-1, an STBC subfield 142-13, the coding type subfield 152-2, a non-sounding subfield 142-14, an AID subfield 142-15, and the additional subfields 142-11 (such as a CRC subfield and a subfield including tail bits), in an embodiment. The AP 14 indicates that the data unit 100 is being transmitted in SU mode by way of setting the bit in the MU/SU subfield 142-6 to a logic "0", according to an embodiment.

According to another embodiment, the MU/SU subfield 142-6 is removed, and the VHT-SIG1 120 includes the group ID subfield 142-7 in both MU mode and SU mode. Therefore, the group ID subfield 142-7 is set to a reserved bit sequence to indicate that the data unit 100 is an SU data unit, in an embodiment.

In SU mode, the VHT-SIG1 120 is implemented without the group ID subfield 142-7, the resolvable LTF subfield 142-8, and the Nss subfield 142-9, according to an embodiment. That is, the data unit 100 does not specify an MU group when supporting SU communication, and enough bits are then freed in the VHT-SIG1 120 to indicate the number of space-time streams for the single client station 25 using the MCS subfield 152-1, thus rendering the Nss subfield 142-9 unnecessary.

In particular, the MCS subfield 152-1 is implemented so that it indicates a number of spatial streams for a client station 25 involved in SU communication, according to an embodiment. This indication is used together with an STBC setting indicated by the STBC subfield 142-13 to provide a complete indication of the number of space-time streams transmitted from the AP 14 to the client 25. By providing this indication in the VHT-SIG1 120 for SU mode as well, one or more embodiments enable the client station 25 to begin estimating the signal channel between the AP 14 and the client station 25 substantially contemporaneously with receipt of the VHT-LTFs 130. The client station 25 then performs signal channel estimation using all or a portion of the VHT-LTFs 130. For example, some of the VHT-LTFs 130 may be repeated, and the client station 25 may therefore perform signal channel estimation using less than all of the VHT-LTFs 130, according to an embodiment.

In yet another embodiment, the Nss subfield 142-9 is not removed, and the VHT-SIG1 120 therefore includes indications of each of the number of spatial streams, the MCS, and the STBC setting in separate subfields. For example, the AID subfield 142-15, or one or more bits from any other suitable subfield or subfields, is/are removed from the example bit allocation of Fig. 9A to allow a sufficient number of bits for the Nss subfield 142-9. In yet another embodiment, as with various other example bit allocations described herein, the Nss subfield 142-9 is replaced with the Nsts subfield 142-12.

Using the STBC subfield 142-13, the AP 14 may have more options for implementing STBC in SU mode. For example, in Fig. 9A, the VHT-SIG1 120 has enough otherwise-unused bits such that the STBC subfield 142-13 includes two bits instead of the single bit in the STBC subfield 142-5. With two bits identifying up to four possible STBC settings, the AP 14 is able to choose between no STBC at all, an Alamouti code, and two higher-order codes, according to an embodiment.

The VHT-SIG1 120 also has enough otherwise-unused bits to include PHY information that is not included in either the VHT-SIG1 120 or the VHT-SIG2 135 in MU mode, in an embodiment. For example, the bit allocation of Fig. 9A includes one bit for the not-sounding subfield 142-14 and three bits for the AID subfield 142-15. The not-sounding subfield 142-14 indicates whether the data unit 100 is a sounding packet, for example. The AID subfield 142-15 includes the last three bits of the MAC ID or AID of a client station to which the data unit 100 is...
being transmitted, in some embodiments. Accordingly, the PHY unit 29 of a client station 25 stops attempting to receive and decode for the duration of the data unit 100 if the PHY unit 29 determines that the AID subfield 142-15 does not match the last three bits of the AID of the client station 25. In this manner, the PHY unit 29 of the client station 25 determines early in the reception of the data unit 100 that the SU transmission is not intended for the client station 25, and conserves power, for example, by not attempting to receive and decode.

[0068] The VHT-SIG2 135 includes the reserved subfield 152-3, the CRC subfield 152-4, and the subfield 152-5 including tail bits. Alternatively, if the reserved subfield 152-3 is not needed to implement any additional features, the VHT-SIG2 135 is simply eliminated from the data unit 100, according to an embodiment.

[0069] Figs. 10A-10C are diagrams of example bit allocations for the VHT-SIG1 120 and the VHT-SIG2 135 for use in MU mode, according to yet another embodiment. As shown in Fig. 10A, the VHT-SIG1 120 includes the bandwidth subfield 142-2, a reserved subfield 142-16, the STBC subfield 142-5, the group ID subfield 142-7, the Nsts subfield 142-12, another reserved subfield 142-17, the SGI subfield 142-3, the coding subfield 152-2, still another reserved subfield 142-18, and the additional subfields 142-11. The VHT-SIG1 120 does not include the duration subfield 142-1, for example. In an embodiment, the duration T of the data unit 100 after the legacy portion is indicated by the rate and length subfields in the L-SIGs 115, such as in the manner described with respect to Fig. 8.

[0070] The bandwidth subfield 142-2 includes two bits to indicate one of four possibilities for the bandwidth of the data unit 100. For example, the bandwidth subfield 142-2 indicates that the bandwidth of the data unit 100 is 20 MHz, 40 MHz, 80 MHz, or 160 MHz (either contiguous or two 80 MHz bands), in an embodiment. The reserved subfield 142-16 includes a single bit set to a logic "1", according to an embodiment. The reserved subfield 142-16 is, for example, reserved for possible expansion of the bandwidth subfield 142-2. The STBC subfield 142-5 includes a single bit indicating whether or not the data unit 100 is encoded using STBC, as described above, in an embodiment. According to an embodiment, the group ID subfield 142-7 is implemented using six bits, and is used to indicate that the data unit 100 is, for example, a SU data unit, as described further below.

[0071] The reserved subfields 142-17 and 142-18 include two bits and six bits, respectively, all of which are set to a logic "1", according to an embodiment. The SGI subfield 142-3 includes two bits, one of which is used to indicate whether the guard interval of the data unit 100 is long or short, and one of which is used for short GI packet length ambiguity mitigation, according to an embodiment. The coding subfield 152-2 includes two bits, at least one of which is used to indicate a coding type used for the data unit 100, such as a binary convolutional code (BCC) or a low-density parity-check (LDPC) code, in an embodiment.

[0072] According to an embodiment, the Nsts subfield 142-12 is implemented using twelve bits, and includes Nsts sub-subfields 142-12-a, 142-12-b, 142-12-c, and 142-12-d to provide an indication of up to four numbers of space-time streams for up to four respective client stations 25, as shown in Fig. 10C. Each of the Nsts sub-subfields 142-12-a, 142-12-b, 142-12-c, and 142-12-d includes, for example, three bits. According to an embodiment, five possible combinations of the three bits in each of the Nsts sub-subfields 142-12-a, 142-12-b, 142-12-c, and 142-12-d are used to indicate that either zero, one, two, three, or four space-time streams correspond to the respective client station 25. Of course, other numbers of possible combinations are used in the Nsts sub-subfields 142-12-a, 142-12-b, 142-12-c, and 142-12-d in other embodiments, such as six possible combinations, seven possible combinations, eight possible combinations, four possible combinations, etc.

[0073] As shown in Fig. 10B, the VHT-SIG2 135 includes a length subfield 152-7, the MCS subfield 152-1, and the subfield 152-5 including tail bits. In an embodiment, the length subfield 152-7 specifies the length of useful data in the physical layer service data unit (PSDU) in units of four octets.

[0074] Figs. 11A and 11B are diagrams of example bit allocations for the VHT-SIG1 120 and the VHT-SIG2 135 for use in SU mode, according to still another embodiment. As shown in Fig. 11A, the VHT-SIG1 120 includes the bandwidth subfield 142-2, the reserved subfield 142-16, the STBC subfield 142-5, the group ID subfield 142-7, the Nsts subfield 142-12, the SGI subfield 142-3, the coding subfield 152-2, still another reserved subfield 142-18, and the additional subfields 142-11. The VHT-SIG1 120 does not include the duration subfield 142-1, for example. In an embodiment, the duration T of the data unit 100 after the legacy portion is indicated by the rate and length subfields in the L-SIGs 115, such as in the manner described with respect to Fig. 8.

[0075] Thus, the VHT-SIG1 120 and the VHT-SIG2 135 have bit allocations similar to the MU mode bit allocations of Figs. 10A and 10B, with several differences which, among other benefits, exploit the increased number of available bits, particularly in the VHT-SIG1 120.

[0076] For example, in an embodiment, the Nsts subfield 142-12 in the VHT-SIG1 120 includes only three bits, compared to the twelve bits allocated in the example of Fig. 10A. The nine bits that are freed up by the smaller size of the Nsts subfield 142-12 in Fig. 11A are allocated to the AID subfield 142-15. As described with respect to Fig. 9A, the AID subfield 142-15 includes bits from the MAC ID or AID of a client station to which the data unit 100 is being transmitted in SU mode, according to some embodiments. For example, in the bit allocation of Fig. 11A, the AID subfield 142-15 includes the last nine bits of the AID of the client station to which the data unit 100 is being transmitted. In an embodiment, the PHY unit 29...
of a client station 25 therefore stops attempting to receive and decode for the duration of the data unit 100, and consequently conserves power, if the PHY unit 29 determines that the AID subfield 142-15 does not match the last nine bits of the AID of the client station 25 (i.e., if the PHY unit 29 determines that the data unit 100 is not intended for the client station 25).

[0077] According to an embodiment, the three bits in the Nsts subfield 142-12 are used to indicate one of eight possible numbers of space-time streams for the client station receiving the data unit 100, such as the client station 25. For example, the three bits in the Nsts subfield 142-12 indicate whether data is transmitted to the client station 25 using one, two, three, four, five, six, seven, or eight space-time streams.

[0078] As noted above, the VHT-SIG1 120 also includes the MCS subfield 152-1 in the example of Fig. 11A, unlike in an MU mode transmission such as that described with respect to Figs. 10A-10C. Additionally, in SU mode, the beamforming subfield 142-19 includes a single bit to indicate whether a beamforming matrix is applied to the data unit 100, in an embodiment.

[0079] In an embodiment, the VHT-SIG1 120 includes the group ID subfield 142-7 in both MU mode and SU mode, and the group ID subfield 142-7 is set to a reserved bit sequence such as, for example, the sequence where every bit in the group ID subfield 142-7 is a logic “1”, to indicate that the data unit 100 is an SU data unit. In an embodiment, the group ID subfield 142-7 is also set to the reserved bit sequence when the data unit 100 is a broadcast frame and when the data unit 100 is an MU data unit but one or more of the client stations 25 have not been assigned to an MU group.

[0080] As further noted above, the VHT-SIG2 135 includes the reserved subfield 152-3 in the example of Fig. 11B. In particular, in at least some SU mode embodiments, bits are allocated to the reserved subfield 152-3 because the MCS subfield 152-1 is included in the VHT-SIG1 120 instead of the VHT-SIG2 135.

[0081] Fig. 12 is a diagram of a data unit 200 that the AP 14 is configured to transmit to the client stations 25 using orthogonal frequency division multiplexing (OFDM) modulation, according to another embodiment. One or more of the client stations 25 is also configured to transmit a data unit formatted according to the format of the data unit 200 to the AP 14, in an embodiment. The data unit 200 conforms to the VHT protocol and occupies an 80 MHz band, in an embodiment. In other embodiments, the data unit 200 occupies a different bandwidth such as discussed with reference to the data unit 100. The data unit 200 is similar to the data unit 100, but a preamble of the data unit 200 includes four very high throughput signal fields (VHT-SIGs) 202 in place of both the VHT-SIG1s 120 and the VHT-SIG2s 135.

[0082] In the data unit 200, content from both the VHT-SIG1 120 and the VHT-SIG2 135 discussed above is included in the VHT-SIGs 202 as further described below. In at least some examples, the VHT-SIGs 202 are collectively referred to as a single very high throughput signal field (VHT-SIG) 202. The VHT-SIG 202 includes three OFDM symbols, according to an embodiment. By providing the VHT-SIG 202 as a unified very high throughput signal field, less bits are utilized as compared to the separate VHT-SIG1 120 and the VHT-SIG2 135 discussed above, and thus more bits are available for signaling other PHY information, in an embodiment. In particular, both the VHT-SIG1 120 and the VHT-SIG2 135 require a set of protection bits at the end thereof, e.g., one or more of the additional subfields 142-11 in the VHT-SIG1 120 and one or both of the CRC subfield 152-4 and the subfield 152-5 including tail bits in the VHT-SIG2 135. Because the single VHT-SIG 202, like each of the VHT-SIG1 120 and the VHT-SIG2 135, has one set of protection bits, other bits are made available that may otherwise have been used as protection bits in the VHT-SIG2 135.

[0083] Figs. 13A and 13B are diagrams of an example bit allocation of the VHT-SIG 202, according to an embodiment. As shown in Fig. 13A, in MU mode, the VHT-SIG 202 includes the duration subfield 142-1, the bandwidth subfield 142-2, the SGI subfield 142-3, the smoothing subfield 142-4, the MU/SU subfield 142-6, a plurality of MU subfields 204, and the additional subfields 142-11, such as a CRC subfield and a subfield including tail bits. As shown in Fig. 13B, the plurality of MU subfields 204 include the group ID subfield 142-7, the resolvable LTF subfield 142-8, a plurality of MU-MCS subfields 204-1, an STBC subfield 204-2, a coding type subfield 204-3, and the MU reserved subfield 142-10.

[0084] The plurality of MU-MCS subfields 204-1 include MU-MCS sub-subfields 204-1-a, 204-1-b, 204-1-c, and 204-1-d, which are denoted MU-MCS 1, MU-MCS2, MU-MCS3, and MU-MCS4, respectively. The MU-MCS sub-subfields 204-1-a, 204-1-b, 204-1-c, and 204-1-d each corresponds to one of the client stations 25-1, 25-2, 25-3, and 25-4, according to an embodiment. According to an embodiment, each of the MU-MCS sub-subfields 204-1-a, 204-1-b, 204-1-c, and 204-1-d includes five bits, and indicates a modulation and coding scheme being used for the corresponding client station 25. Of the 32 possible different sequences of five bits, one sequence is used to indicate that no data is being transmitted to the corresponding client station 25, in an embodiment. Therefore, any of 31 different MCSs are used for each client station 25, according to an embodiment. According to another embodiment, less than 31 different MCSs may be available for use, and the number of bits allocated to each of the MU-MCS subfields 204-1 is correspondingly reduced.

[0085] The MU-MCS subfields 204-1 are implemented so that they each indicate a number of spatial streams for a respective client station 25, along with an indication of the modulation and coding scheme for the respective client station 25, according to an embodiment. The STBC subfield 204-2 also provides an indication of user-specific STBC settings in the VHT-SIG 202. For example, the STBC subfield 204-2 includes four bits, where each bit...
In a manner similar to various embodiments described in, the additional usable bits in the VHT-SIG 202 allow user-specific control of both MCSs and STBC settings, in an embodiment. According to an embodiment, the coding type subfield 204-3 is implemented in a manner similar to the STBC subfield 204-2 to allow user-specific control of coding type.

In a manner similar to various embodiments described above, the MU-MCS subfields 204-1, and the bits within the STBC subfield 204-2, are ordered according to unique index values assigned to the client stations 25 by the AP 14. Therefore, the MU-MCS subfields 204-1 are used together with the STBC subfield 204-2 to provide a complete indication of the number of space-time streams transmitted from the AP 14 to each of the client stations 25.

Figs. 14A and 14B are diagrams of an example bit allocation of the VHT-SIG 202 in SU mode, according to an embodiment. As shown in Fig. 14A, the VHT-SIG 202 includes the duration subfield 142-1, the bandwidth subfield 142-2, the SGI subfield 142-3, the smoothing subfield 142-4, the MU/SU subfield 142-5, a plurality of SU subfields 206, and the additional subfields 142-11, such as a CRC subfield and a subfield including tail bits, in an embodiment. As shown in Fig. 14B, the plurality of SU subfields 206 includes the MCS subfield 152-1, the STBC subfield 142-13, the coding type subfield 152-2, the non-sounding subfield 142-14, the AID subfield 142-15, and an SU reserved subfield 206-1.

In an embodiment, the MU/SU subfield 142-6 is removed in both MU and SU mode, and the VHT-SIG 202 includes the group ID subfield 142-7 in both MU mode and SU mode. Therefore, the group ID subfield 142-7 is set to a reserved bit sequence to indicate that the data unit 200 is an SU data unit, in an embodiment. The MCS subfield 152-1, the STBC subfield 142-13, the coding type subfield 152-2, the non-sounding subfield 142-14, and the AID subfield 142-15 are implemented in a similar manner as described above with respect to Fig. 9A, for example. The SU reserved subfield 206-1 includes bits allocated for implementation of future SU features. According to an embodiment, the AID subfield 142-15 includes more than three bits in order to improve differentiation among client stations, thereby allowing the PHY unit 29 of a client station 25 to more reliably determine that the AID subfield 142-15 does not correspond to the client station 25 (e.g., to an AID of the client station 25) and, in response, shut down for the duration of the data unit 200. The SU reserved subfield 206-1 may include fewer than 24 bits when the AID subfield 142-15 includes more than three bits.

In at least some embodiments and/or situations, one or more advantages are realized by using the data unit 200 and, in particular, the unified VHT-SIG 202 therein. As described above, bit savings is achieved, in at least some embodiments, thereby allowing other information, such as more user-specific information in an MU scenario, to be signaled in the VHT-SIG 202. In some cases, the bit savings eliminate the need to implement an LUT in connection with, for example, the Nss subfield 142-9 or the Nsts subfield 142-12. Consequently, processing delay and complexity resulting from searching such an LUT is reduced, in some embodiments. Implementation of the PHY unit 29 of each client station 25 also is simplified, in some embodiments, because of the simpler demodulation and decoding attendant to a data unit having a single signal field as opposed to multiple signal fields (e.g., the VHT-SIG1 120 and the VHT-SIG2 135). Additionally, the VHT-SIG 202 allows a single preamble structure to be used for both SU and MU situations, in some embodiments, whereas in some embodiments described above, the VHT-SIG2 135 is used in MU situations but eliminated in SU situations. In MU situations, the VHT-SIG 202 also enables each client station 25 to perform more advanced interference mitigation (or "whitening"), because the constellation of interference for the client station 25 is more well-known by virtue of the client station 25 receiving all very high throughput signal field information via the omnidirectional VHT-SIG 202, in an embodiment. The VHT-SIG2 135, on the other hand, is beam-steered to different client stations 25 in some embodiments, as discussed above. Consequently, in some embodiments, the VHT-SIG 202 is decoded more reliably than the combination of the VHT-SIG1 120 and the VHT-SIG2 135. The VHT-SIG 202 also allows more reserved bits for both MU and SU situations, and therefore better accommodates foreseeable, yet-to-be-developed advanced features, in some embodiments.

Fig. 15 is a diagram of yet another data unit 300 that the AP 14 is configured to transmit to the client stations 25 using orthogonal frequency division multiplexing (OFDM) modulation, according to another embodiment. One or more of the client stations 25 also are configured to transmit a data unit formatted according to the format of the data unit 300 to the AP 14. The data unit 300 conforms to the VHT protocol and occupies an 80 MHz band, in an embodiment. In other embodiments, the data unit 300 occupies a different bandwidth such as discussed with reference the data unit 100. The data unit 300 is similar to the data unit 200, but a preamble of the data unit 300 includes four very high throughput signal fields (VHT-SIGs) 302 instead of the VHT-SIG 202. In at least some examples, the VHT-SIGs 302 are collectively referred to as a single very high throughput signal field (VHT-SIG) 302. The VHT-SIG 302 has a different format than the VHT-SIG 202, as discussed below.

According to an embodiment, the VHT-SIG 302 includes only two OFDM symbols, as compared to three OFDM symbols for the VHT-SIG 202 of Fig. 12. The L-SIGs 115 are used to indicate the duration T of the data unit 300 after the legacy portion by appropriately setting the rate and length subfields in the L-SIGs 115, such as in a manner similar to that described above with respect to Fig. 8. As a result, the twelve bits of the duration subfield 142-1 are not included in the VHT-SIG 302, and bits
are allocated to the remaining subfields of the VHT-SIG 302 such that only two OFDM symbols are utilized for transmission of the VHT-SIG 302.

[0093] Fig. 16 is a diagram of an example bit allocation for the VHT-SIG 302 in MU mode. The VHT-SIG 302 includes the bandwidth subfield 142-2, the SGI subfield 142-3, the smoothing subfield 142-4, the STBC subfield 142-5, the non-sounding subfield 142-14, the coding type subfield 152-2, the group ID subfield 142-7, the MU-MCS subfields 204-1, the MU reserved subfield 142-10, and the additional subfields 142-11.

[0094] As in the example bit allocation of Figs. 13A and 13B, the MU-MCS subfields 204-1 are implemented so that they each indicate a number of spatial streams for a respective client station 25, along with an indication of the modulation and coding scheme for the respective client station 25, according to an embodiment. The STBC subfield 142-5 indicates an STBC setting that is common to all of the client stations 25, according to an embodiment. Therefore, the MU-MCS subfields 204-1 are used together with the STBC subfield 142-5 to provide a complete indication of the number of space-time streams transmitted from the AP 14 to each of the client stations 25, while using only two OFDM symbols to transmit the entire very high throughput signal content of the preamble.

[0095] Fig. 17 is a diagram of an example bit allocation for the VHT-SIG 302 in SU mode. The VHT-SIG 302 includes the bandwidth subfield 142-2, the SGI subfield 142-3, the smoothing subfield 142-4, the STBC subfield 142-5, the non-sounding subfield 142-14, the coding type subfield 152-2, the group ID subfield 142-7, an SU-MCS subfield 304-1, the AID subfield 142-15, the SU reserved subfield 206-1, and the additional subfields 142-11.

[0096] Accordingly, the preamble of the data unit 300 is formatted in substantially the same manner for both SU mode and MU mode, allowing for greater simplicity in the design of the PHY units 29 for the client stations 25. For example, the group ID subfield 142-7 is included for both SU mode and MU mode. According to an embodiment, the group ID subfield 142-7 is set to a particular reserved bit sequence, such as the sequence having every bit set to a logic "0", to indicate SU mode, and MU mode is indicated any time the group ID subfield 142-7 differs from the reserved sequence, such as when the group ID subfield 142-7 has one or more bits set to a logic "1". In another embodiment, the MU/SU subfield 142-6 is included in both MU and SU mode, and the group ID subfield 142-7 is removed in SU mode.

[0097] The SU-MCS subfield 304-1 is implemented such that it indicates a number of spatial streams, along with an indication of a modulation and coding scheme, for a client station to which the data unit 300 is transmitted in SU mode, according to an embodiment. The SU-MCS subfield 304-1 is used together with the STBC subfield 142-5 to indicate the number of space-time streams transmitted from the AP 14 to the intended client station.

[0098] As described with respect to Figs. 9A and 9B, the AID subfield 142-15 allows early shut down of the PHY unit 29 of a client station 25 if the PHY unit 29 determines that the client station 25 is not the client station for which the SU transmission is intended, according to an embodiment.

[0099] The same or similar preambles as described with respect to each of the data units 100, 200, and 300 are usable for uplink (UL) MIMO transmissions as well. For MU mode operation using the data unit 100, the AP 14 sends an uplink start indication (USI) frame to the client stations 25. The USI frame indicates all of the PHY information for each client station 25 except for user-specific information that each client station 25 includes in a beam-steered very high throughput signal field (e.g., the VHT-SIG2 135), such as an MCS, STBC setting, coding type, etc. Accordingly to an embodiment, the client stations 25 do not control any PHY information in UL-MIMO transmissions that is not included in the VHT-SIG2 135 or a similar beam-steered signal field. Instead, any information included in a signal field common to all the client stations 25 (e.g., the VHT-SIG1 120) is required to be controlled by the AP 14, because the AP 14 is better suited to determine conditions of other client stations 25, in an embodiment. For example, the AP 14 may know interference levels across all of the client stations 25, the received signal strength for UL transmissions by each client station 25, the transmit power of each client station 25, etc. Accordingly, in data units such as the data units 200 and 300, where all very high throughput signal field information is omnidirectional, the AP 14 controls information such as the MCS, STBC setting, etc., which is included in the VHT-SIG 202 or the VHT-SIG 302, for example.

[0100] Fig. 18 is a flow chart of an example method 400 for generating a preamble of a data unit for transmission via a communication channel, according to an embodiment. The method 400 will be described with reference to various embodiments of the WLAN 10 and the data units 100, 200, and 300, for ease of explanation. It will be understood, however, that the method 400 is used in networks other than the WLAN 10, and/or is used to generate a preamble of a data unit other than the data units 100, 200, and 300, in some embodiments. Additionally, the PHY unit 20 is configured to perform the method 400, in an embodiment. However, it will be understood that other devices are configured to perform the method 400 in other embodiments. As just one example, the MAC unit 18 is configured to perform at least a portion of the method 400, in an embodiment. It will further be understood that the PHY unit 20 is configured to perform methods other than the method 400, in some embodiments.

[0101] At block 402, an indication of a first number of spatial or space-time streams is included in a first field of the preamble. The indication of the first number of streams corresponds to transmission of the data unit to a first receiver, e.g., the client station 25-1. The first field of the preamble is the VHT-SIG1 120, in one embry-
ment. In another embodiment, the first field is the VHT-SIG 202. In yet another embodiment, the first field is the VHT-SIG 302.

[0102] At block 404, one or more training sequences included in a second field of the preamble. The indication of the first number of streams indicates that a first set of the one or more training sequences in the second field, e.g., a first set of the VHT-LTFs 130, corresponds to the first receiver.

[0103] At block 406, the preamble is formatted such that the first field of the preamble will be transmitted prior to the second field of the preamble being transmitted. Accordingly, the client station 25-1 receives the indication of the first number of spatial or space-time streams, and therefore the indication that the first set of the VHT-LTFs 130 corresponds to the client station 25-1, before receiving the VHT-LTFs 130, according to an embodiment.

[0104] One of ordinary skill in the art will recognize suitable variations of the method 400 in light of the teaching and disclosure herein. For example, in some embodiments, one or more features shown in Fig. 18 are not performed, and/or one or more additional features not shown in Fig. 18 are performed. In another example, the order shown in Fig. 18 does not indicate the order in which the method 400 is performed, and/or does not indicate that each block is completed before another block begins.

[0105] Fig. 19 is a flow chart of an example method 500 for receiving a preamble of a data unit via a communication channel using a first receiver, according to an embodiment. The method 500 will be described with reference to various embodiments of the WLAN 10 and the data units 100, 200, and 300, for ease of explanation. It will be understood, however, that the method 500 is used in networks other than the WLAN 10, and/or is used to receive a preamble of a data unit other than the data units 100, 200, and 300, in some embodiments. Additionally, the PHY unit 29 is configured to perform the method 500, in an embodiment. However, it will be understood that other devices are configured to perform the method 500 in other embodiments. It will further be understood that the PHY unit 29 is configured to perform methods other than the method 500, in some embodiments.

[0106] At block 502, a first field of the preamble is received. The first field includes an indication of a first number of spatial or space-time streams of the data unit which correspond to the first receiver, e.g., the client station 25-1.

[0107] At block 504, it is determined that a first set of one or more training sequences in a second field of the preamble corresponds to the first receiver. Accordingly, upon receiving the second field of the preamble, the client station 25-1 already knows which ones of the VHT-LTFs 130 correspond to the client station 25-1, according to an embodiment. The determination at block 504 is made in any of various suitable ways, such as in one of the example ways described above, according to various embodiments.
According to various embodiments, at least one client station 25-3, 25-4, etc., in some embodiments.

According to an embodiment.

The reality of training sequences within the VHT-LTFs 130, therefore used to indicate the locations of sets of the plurality of receivers, such as the client station 25-2, according to an embodiment. Other unique index values are of the plurality of receivers, in some embodiments. For example, the unique index value corresponding to the client station 25-1, in an embodiment. More specifically, in an embodiment, an indicator of the number of spatial or space-time streams that corresponds to transmission of the data unit to the second receiver is an indicator of the set of the plurality of training sequences that corresponds to transmission of the data unit to the second receiver, in an embodiment. Additionally, an indication of the number of spatial or space-time streams that corresponds to transmission of the data unit to the second receiver is an indicator of the set of the plurality of training sequences that corresponds to transmission of the data unit to the second receiver. Additionally, an indication of the number of spatial or space-time streams that corresponds to transmission of the data unit to the first receiver is further a further indicator of the set of the plurality of training sequences that corresponds to transmission of the data unit to the first receiver.

Unique index values are used to indicate the order in which the plurality of indicators of the sets of the plurality of training sequences will be provided to the plurality of receivers, in some embodiments. For example, each unique index value corresponds to one of the plurality of receivers, in an embodiment. For example, the unique index value corresponding to the client station 25-1 indicates the position or order of a subfield of the first field of the preamble, relative to other subfields of the first field of the preamble, which corresponds to the client station 25-1. The subfield which corresponds to the client station 25-1, in turn, includes an indication of a number of spatial or space-time streams corresponding to transmission of the data unit to the client station 25-1, or another suitable indication of the set of the plurality of training sequences which corresponds to the client station 25-1, according to an embodiment. Other unique index values may be used in similar ways for other ones of the plurality of receivers, such as the client station 25-2, the client station 25-3, etc.. The unique index values are therefore used to indicate the locations of sets of the plurality of training sequences within the VHT-LTFs 130, according to an embodiment.

At block 604, the plurality of training sequences is included in a second field of the preamble.

At block 606, the preamble is formatted such that the first field of the preamble will be transmitted prior to the second field of the preamble being transmitted. Accordingly, each of the plurality of receivers receives an indication of a set of the plurality of training sequences that corresponds to transmission of the data unit to the receiver before receiving the VHT-LTFs 130, according to an embodiment.

One of ordinary skill in the art will recognize suitable variations of the method 600 in light of the teaching and disclosure herein. For example, in some embodiments, one or more features shown in Fig. 20 are not performed, and/or one or more additional features not shown in Fig. 20 are performed. In another example, the order shown in Fig. 20 does not indicate the order in which the method 600 is performed, and/or does not indicate that each block is completed before another block begins.

Fig. 21 is a flow chart of an example method 700 for receiving a preamble of a data unit via a multi-user MIMO (MU-MIMO) communication channel using a first receiver, such as using the PHY unit 29 of the client station 25-1, according to an embodiment. The method 700 will be described with reference to various embodiments of the WLAN 10 and the data units 100, 200, and 300, for ease of explanation. It will be understood, however, that the method 700 is used in networks other than the WLAN 10, and/or is used to receive a preamble of a data unit other than the data units 100, 200, and 300, in some embodiments. Additionally, the PHY unit 29 is configured to perform the method 700, in an embodiment. However, it will be understood that other devices are configured to perform the method 700 in other embodiments. It will further be understood that the PHY unit 29 is configured to perform methods other than the method 700, in some embodiments.

At block 702, a first field of the preamble is received. The first field provides a plurality of indicators to a plurality of receivers. The plurality of receivers includes the first receiver, e.g., the client station 25-1, in an embodiment. According to an embodiment, each indicator corresponds to one of the plurality of receivers, and each indicator indicates a set of a plurality of training sequences that corresponds to transmission of the data unit to the corresponding receiver. For example, the first field of the preamble provides an indicator to the client station 25-1 of a first set of the plurality of training sequences that corresponds to transmission of the data unit to the client station 25-1, in an embodiment. The first field of the preamble further provides an indicator to the client station 25-2 of a second set of the plurality of training sequences that corresponds to transmission of the data unit to the client station 25-2, in an embodiment, and/or provides corresponding indicators of sets of the plurality of training sequences to the client stations 25-3, 25-4, etc., in some embodiments.

As described with respect to the method 600,
in various embodiments, the indicator that corresponds to the first receiver includes an indication of a number of spatial streams corresponding to transmission of the data unit to the first receiver; an indication of a number of space-time streams corresponding to transmission of the data unit to the first receiver; an indication of a number of training fields corresponding to transmission of the data unit to the first receiver; or any suitable indication of a position of a set of training sequences within, for example, the VHT-LTFs 130, that corresponds to transmission of the data unit to the first receiver. In an embodiment, a second one of the plurality of indicators that corresponds to a second one of the plurality of receivers is a further indicator of the set of the plurality of training sequences that corresponds to transmission of the data unit to the first receiver; or any suitable indication of a number of spatial or space-time streams corresponding to transmission of the data unit to the first receiver; or any suitable indication of a number of training fields corresponding to transmission of the data unit to the first receiver. For example, in an embodiment, an indicator of the set of the plurality of training sequences within the VHT-LTFs 130, that corresponds to transmission of the data unit to the first receiver; an indication of a number of spatial or space-time streams corresponding to transmission of the data unit to the first receiver; an indication of a number of spatial or space-time streams corresponding to transmission of the data unit to the first receiver includes an indication of a number of spatial or space-time streams corresponding to transmission of the data unit to the first receiver. In various embodiments, where a second one of the plurality of indicators that corresponds to a second one of the plurality of receivers is a further indicator of the set of the plurality of training sequences that corresponds to transmission of the data unit to the first receiver, the determination at block 704 is made further based on the second one of the plurality of indicators.

At block 706, a second field of the preamble is received. The second field of the preamble includes the plurality of training sequences. Therefore, based on the result of block 704, the client station 25-1 already knows, upon receiving at least some of the VHT-LTFs 130, which ones of the VHT-LTFs 130 correspond to the client station 25-1, according to an embodiment.

At block 708, the first set of training sequences is utilized to generate an estimate of at least a portion of the communication channel between a transmitter, such as the AP 14, and the first receiver, such as the client station 25-1. In an embodiment, at least a portion of block 708 is performed while performing block 706. Accordingly, the method 700 allows the communication channel to be estimated earlier by virtue of providing a way to determine that the first set of training sequences corresponds to the first receiver, before receiving at least some of the training sequences, in an embodiment.

One of ordinary skill in the art will recognize suitable variations of the method 700 in light of the teaching and disclosure herein. For example, in some embodiments, one or more features shown in Fig. 21 are not performed, and/or one or more additional features not shown in Fig. 21 are performed. In another example, the order shown in Fig. 21 does not indicate the order in which the method 700 is performed, and/or does not indicate that each block is completed before another block begins.

At least some of the various blocks, operations, and techniques described above may be implemented utilizing hardware, a processor executing firmware instructions, a processor executing software instructions, or any combination thereof. When implemented utilizing a processor executing software or firmware instructions, the software or firmware instructions may be stored in any computer readable memory such as on a magnetic disk, an optical disk, or other storage medium, in a RAM or ROM or flash memory, processor, hard disk drive, optical disk drive, tape drive, etc. Likewise, the software or firmware instructions may be delivered to a user or a system via any known or desired delivery method including, for example, on a computer readable disk or other transportable computer storage mechanism or via communication media. Communication media typically embodies computer readable instructions, data structures, program modules or other data in a modulated data signal such as a carrier wave or other transport mechanism. The term "modulated data signal" means a signal that has one or more of its characteristics set or changed in such a manner as to encode information in the signal. By way of example, and not limitation, communication
media includes wired media such as a wired network or direct-wired connection, and wireless media such as acoustic, radio frequency, infrared and other wireless media. Thus, the software or firmware instructions may be delivered to a user or a system via a communication channel such as a telephone line, a DSL line, a cable television line, a fiber optics line, a wireless communication channel, the Internet, etc. (which are viewed as being the same as or interchangeable with providing such software via a transportable storage medium). The software or firmware instructions may include machine readable instructions that, when executed by the processor, cause the processor to perform various acts.

**[0127]** When implemented in hardware, the hardware may comprise one or more of discrete components, an integrated circuit, an application-specific integrated circuit (ASIC), etc.

**[0128]** While the present invention has been described with reference to specific examples, which are intended to be illustrative only and not to be limiting of the invention, changes, additions and/or deletions may be made to the disclosed embodiments without departing from the scope of the invention.

### Claims

1. A method for generating a preamble of a data unit (100) for transmission via a multiple input, multiple output MIMO communication channel, the method comprising: generating a first field (120) of the preamble that provides a plurality of indicators (142-9) to a plurality of receivers, wherein each one of the plurality of indicators indicates a set of a plurality of training sequences that corresponds to transmission of the data unit to a corresponding one of the plurality of receivers; including the plurality of training sequences (130) in a second field (VHT PORTION) of the preamble; and formatting the preamble such that the first field of the preamble will be transmitted prior to the second field of the preamble being transmitted.

2. A method according to claim 1, wherein a first one of the plurality of indicators indicates a first number of spatial or space-time streams that corresponds to transmission of the data unit to a first one of the plurality of receivers.

3. A method according to claim 1, wherein a first one of the plurality of indicators that corresponds to a first one of the plurality of receivers is a further indicator to a second one of the plurality of receivers of the set of the plurality of training sequences that corresponds to transmission of the data unit to the second receiver.

4. A method according to any one of claims 1 to 3, further comprising communicating to the plurality of receivers, before transmitting the first field of the preamble, an order in which the first field of the preamble will provide the plurality of indicators of the sets of the plurality of training sequences to the plurality of receivers.

5. A method according to any one of claims 1 to 4, further comprising including a group identifier corresponding to the plurality of receivers in a third field of the preamble.

6. An apparatus (14), comprising: a physical layer PHY unit configured to:

   * generate a preamble of a data unit (100) for transmission via a multiple input, multiple output MIMO communication channel, wherein, a first field (120) of the preamble provides a plurality of indicators (142-9) to a plurality of receivers, wherein each one of the plurality of indicators indicates a set of a plurality of training sequences that corresponds to transmission of the data unit to a corresponding one of the plurality of receivers, and the preamble includes a second field (VHT PORTION) having the plurality of training sequences (130); and
   * wherein the PHY unit is further configured to cause the first field of the preamble to be transmitted prior to the second field of the preamble being transmitted.

7. An apparatus according to claim 6, wherein a first one of the plurality of indicators indicates a first number of spatial or space-time streams that corresponds to transmission of the data unit to a first one of the plurality of receivers, or wherein a first one of the plurality of indicators that corresponds to a first one of the plurality of receivers is a further indicator to a second one of the plurality of receivers of the set of the plurality of training sequences that corresponds to transmission of the data unit to the second receiver.

8. An apparatus according to claim 6 or 7, wherein the PHY unit is further configured to communicate to the plurality of receivers, before transmitting the first field of the preamble, an order in which the first field of the preamble will provide the plurality of indicators of the sets of the plurality of training sequences to the plurality of receiver, and/or wherein the PHY unit is further configured to include a group identifier corresponding to the plurality of...
receivers in a third field of the preamble.

9. A method for receiving a preamble of a data unit (100) via a multiple input, multiple output MIMO communication channel using a first receiver, the method comprising:

receiving a first field (120) of the preamble, wherein the first field of the preamble provides a plurality of indicators (142-9),

wherein each one of the plurality of indicators indicates a set of a plurality of training sequences that corresponds to transmission of the data unit to a corresponding one of a plurality of receivers, wherein the first receiver is one of the plurality of receivers;

determining that a first set of the plurality of training sequences corresponds to the first receiver based on the one of the plurality of indicators that corresponds to the first receiver;

receiving a second field (VHT PORTION) of the preamble after receiving the first field of the preamble, wherein the second field of the preamble comprises the plurality of training sequences (130); and

utilizing the first set of the plurality of training sequences to generate an estimate of at least a portion of the MIMO communication channel.

10. A method according to claim 9, wherein the indicator that corresponds to the first receiver indicates a first number of spatial or space-time streams that corresponds to transmission of the data unit to the first receiver.

11. A method according to claim 9 or 10, wherein determining that the first set of the plurality of training sequences corresponds to the first receiver is further based on a second one of the plurality of indicators that corresponds to a second one of the plurality of receivers.

12. A method according to any of claims 9 to 11, further comprising:

receiving an indication of an order in which the first field of the preamble provides the plurality of indicators of the sets of the plurality of training sequences to the plurality of receivers, before receiving the first field of the preamble; and

determining that the first set of the plurality of training sequences corresponds to the first receiver further based on the indication of the order.

13. A method according to any of claims 9 to 12, further comprising:

receiving a third field of the preamble, wherein the third field of the preamble includes a group identifier corresponding to the plurality of receivers; and

determining that the first set of the plurality of training sequences corresponds to the first receiver further based on the group identifier.

14. An apparatus (25), comprising:

a physical layer PHY unit (29) configured to:

receive a first field (120) of a preamble of a data unit via a multiple input, multiple output MIMO communication channel, wherein the first field of the preamble provides a plurality of indicators (142-9), wherein each one of the plurality of indicators indicates a set of a plurality of training sequences that corresponds to transmission of the data unit to a corresponding one of a plurality of receivers, and wherein a first one of the plurality of receivers comprises the apparatus;

receive a second field (VHT PORTION) of the preamble after receiving the first field of the preamble, wherein the second field of the preamble includes the plurality of training sequences (130); and

utilize the first set of the plurality of training sequences to generate an estimate of at least a portion of the MIMO communication channel.

15. An apparatus according to claim 14, wherein the indicator that corresponds to the first receiver indicates a first number of spatial or space-time streams that corresponds to transmission of the data unit to the first receiver, and/or

wherein the PHY unit is further configured to determine that the first set of the plurality of training sequences corresponds to the first receiver further based on a second one of the plurality of indicators that corresponds to a second one of the plurality of receivers, and/or

wherein the PHY unit is further configured to receive an indication of an order in which the first field of the preamble provides the plurality of indicators of the sets of the plurality of training sequences to the plurality of receivers, before receiving the first field of the preamble, and determine that the first set of the plurality of training sequences corresponds to the first receiver further based on the indication of the order.
Patentansprüche

1. Verfahren zum Erzeugen einer Präambel einer Dateneinheit (100) für die Sendung über einen MIMO-Kommunikationskanal (MIMO-Multiple Input Multiple Output), wobei das Verfahren umfasst:

- Erzeugen eines ersten Feldes (120) der Präambel, die eine Vielzahl von Kennungen (142-9) für eine Vielzahl von Empfängern bereitstellt, wobei jede aus der Vielzahl von Kennungen einen Satz einer Vielzahl von Trainingssequenzen angibt, der der Sendung der Dateneinheit zu einem entsprechenden aus der Vielzahl von Empfängern entspricht;
- Einschließen der Vielzahl von Trainingssequenzen (130) in ein zweites Feld (VHT-AB-SCHNITT) der Präambel; und
- Formatieren der Präambel derart, dass das erste Feld der Präambel gesendet wird, bevor das zweite Feld der Präambel gesendet wird.

2. Verfahren nach Anspruch 1, bei dem eine erste aus der Vielzahl von Kennungen eine erste Zahl von räumlichen Strömen oder Raum-Zeit-Strömen kennzeichnet, die einer Sendung der Dateneinheit zu einem ersten aus der Vielzahl von Empfängern entspricht.

5. Verfahren nach einem der Ansprüche 1 bis 4, weiterhin umfassend das Einschließen einer Gruppenkennung, die der Vielzahl von Empfängern entspricht, in ein drittes Feld der Präambel.

6. Gerät (14), umfassend:

   - eine Einheit einer physikalischen Ebene, die dazu eingerichtet ist:
     - eine Präambel einer Dateneinheit (100) für die Sendung über einen MIMO-Kommunikationskanal (MIMO-Multiple Input Multiple Output) zu erzeugen, wobei ein erstes Feld (120) der Präambel eine Vielzahl von Kennungen (142-9) für eine Vielzahl von Empfängern bereitstellt, wobei jede aus der Vielzahl von Kennungen einen Satz einer Vielzahl von Trainingssequenzen angibt, der der Sendung der Dateneinheit zu einem entsprechenden aus der Vielzahl von Empfängern entspricht, und
     - die Präambel ein zweites Feld (VHT-AB-SCHNITT) umfasst, das die Vielzahl von Trainingssequenzen (130) umfasst; und
     - die PHY-Einheit weiterhin dazu eingerichtet ist, die PHY-Einheit weiterhin dazu eingerichtet ist, das erste Feld der Präambel gesendet wird, bevor das zweite Feld der Präambel gesendet wird.

   - die PHY-Einheit weiterhin dazu eingerichtet ist, eine Gruppenkennung, die der Vielzahl von Empfängern entspricht, in ein drittes Feld der Präambel einzuschließen.

9. Verfahren zum Empfangen einer Präambel einer Dateneinheit (100) über einen MIMO-Kommunikationskanal (MIMO-Multiple Input Multiple Output) mit Hilfe eines ersten Empfängers, wobei das Verfahren umfasst:
Empfangen eines ersten Feldes (120) der Präambel, wobei das erste Feld der Präambel eine Vielzahl von Kennungen (142-9) bereitstellt, wobei jede aus der Vielzahl von Kennungen einen Satz einer Vielzahl von Trainingssequenzen angibt, der der Sendung der Dateneinheit zu einem entsprechenden aus einer Vielzahl von Empfängern entspricht, wobei der erste Empfänger einer aus der Vielzahl von Empfängern ist;

10. Verfahren nach Anspruch 9, bei dem die Kennung, die dem ersten Empfänger entspricht, eine erste Zahl von räumlichen Strömen oder Raum-Zeit-Strömen angibt, die der Sendung der Dateneinheit zu dem ersten Empfänger entspricht;

12. Verfahren nach einem der Ansprüche 9 bis 11, weiterhin umfassend:

Empfangen einer Kennung einer Reihenfolge, in der das erste Feld der Präambel die Vielzahl von Kennungen der Sätze der Vielzahl von Trainingssequenzen der Vielzahl von Empfängern bereitstellt, bevor das erste Feld der Präambel empfangen wird; und

Bestimmen, dass der erste Satz der Vielzahl von Trainingssequenzen dem ersten Empfänger entspricht, weiterhin auf der Basis der Kennung der Reihenfolge.

13. Verfahren nach einem der Ansprüche 9 bis 12, weiterhin umfassend:

Empfangen eines dritten Feldes der Präambel, wobei das dritte Feld der Präambel eine Gruppenkennung umfasst, die der Vielzahl von Empfängern entspricht; und

Bestimmen, dass der erste Satz der Vielzahl von Trainingssequenzen dem ersten Empfänger entspricht, weiterhin auf der Basis der Gruppenkennung.

14. Gerät (25), umfassend:

eine Einheit (29) einer physikalischen Ebene PHY, die dazu eingerichtet ist:

ein erstes Feld (120) einer Präambel einer Dateneinheit über einen MIMO-Kommunikationskanal (MIMO-Multiple Input Multiple Output) zu empfangen, wobei das erste Feld der Präambel eine Vielzahl von Kennungen (142-9) bereitstellt, wobei jede aus der Vielzahl von Kennungen einen Satz einer Vielzahl von Trainingssequenzen angibt, der der Sendung der Dateneinheit zu einem entsprechenden aus der Vielzahl von Empfängern entspricht und ein erster aus der Vielzahl von Empfängern das Gerät umfasst; dass der erste Satz aus der Vielzahl der Trainingssequenzen dem ersten Empfänger entspricht, auf der Basis der einen aus der Vielzahl von Kennungen zu bestimmen, die dem ersten Empfänger entspricht; ein zweites Feld (VHT-AB-SCHNITT) der Präambel nach dem Empfang des ersten Feldes der Präambel zu empfangen, wobei das zweite Feld der Präambel die Vielzahl von Trainingssequenzen (130) umfasst; und

den ersten Satz der Vielzahl von Trainingssequenzen zu verwenden, um eine Bewertung wenigstens eines Teils des MIMO-Kommunikationskanals zu erzeugen.

15. Gerät nach Anspruch 14, bei dem die Kennung, die dem ersten Empfänger entspricht, eine erste Zahl von räumlichen Strömen oder Raum-Zeit-Strömen angibt, die der Sendung der Dateneinheit zu dem ersten Empfänger entspricht und/oder die PHY-Einheit weiterhin dazu eingerichtet ist, dass der erste Satz der Vielzahl von Trainingssequenzen dem ersten Empfänger entspricht, weiterhin auf der Basis einer zweiten aus der Vielzahl von Kennungen zu bestimmen, die einem zweiten aus der Vielzahl von Empfängern entspricht, und/oder

die PHY-Einheit weiterhin dazu eingerichtet ist, eine Kennung einer Reihenfolge zu empfangen, in der das erste Feld der Präambel die Vielzahl von Kennungen der Sätze der Vielzahl von Trainingssequenzen bereitstellt, bevor das erste Feld der Präambel empfangen wird, und

dass der erste Satz der Vielzahl der Trainingssequenzen dem ersten Empfänger entspricht.
quenzen dem ersten Empfänger entspricht, weiterhin auf der Basis der Kennung der Reihenfolge zu bestimmen, und/oder
die PHY-Einheit weiterhin dazu eingerichtet ist, ein
drittes Feld der Präambel zu empfangen, wobei das
dritte Feld der Präambel eine Gruppenkennung umfasst, die der Vielzahl von Empfängern entspricht,
und, dass der erste Satz der Vielzahl von Trainingssequenzen dem ersten Empfänger entspricht, weiterhin auf der Basis der Gruppenkennung zu bestimmen.

Revendications

1. Procédé de génération de préambule d’une unité de données (100) pour transmission par l’intermédiaire
   d’un canal de communication à entrées multiples, sorties multiples, MIMO, le procédé comprenant :
   la génération d’un premier champ (120) du préambule qui fournit une pluralité d’indicateurs
   (142-9) à une pluralité de récepteurs, dans lequel chaque indicateur de la pluralité d’indicateurs
   indique un ensemble d’une pluralité de séquences d’apprentissage qui correspond à la transmis-
   sion de l’unité de données à un récepteur correspondant de la pluralité de récepteurs ;
   l’inclusion de la pluralité de séquences d’apprentissage (130) dans un deuxième champ
   (VHT PORTION) du préambule ; et
   le formatage du préambule de sorte que le premier champ du préambule soit transmis avant le
deuxième champ du préambule transmis.

2. Procédé selon la revendication 1, dans lequel un premier indicateur de la pluralité d’indicateurs indique
   un premier nombre de courants spatiaux ou spatio-temporels qui correspond à la transmission de l’unité
   de données à un premier récepteur de la pluralité de récepteurs.

3. Procédé selon la revendication 1, dans lequel un premier indicateur de la pluralité d’indicateurs qui cor-
   respon du premier récepteur de la pluralité de récepteurs est un autre indicateur pour un deuxième
   récepteur de la pluralité de récepteurs de l’ensemble de la pluralité de séquences d’apprentissage qui cor-
   respon à la transmission de l’unité de données du deuxième récepteur.

4. Procédé selon l’une quelconque des revendications
   1 à 3, comprenant en outre la communication à la pluralité de récepteurs, avant la transmission du pre-
   mier champ du préambule, d’un ordre dans lequel le premier champ du préambule fournit la pluralité
   d’indicateurs des ensembles de séquences de la plu-

5. Procédé selon l’une quelconque des revendications
   1 à 4, comprenant en outre l’inclusion d’un identifiant de groupe correspondant à la pluralité de récepteurs dans un troisième champ du préambule.

6. Dispositif (14) comprenant :
   une unité de couche physique PHY configurée pour :
   générer un préambule d’une unité de données (100) pour transmission par l’intermé-
   diaire d’un canal de communication à entrées multiples, sorties multiples, MIMO, dans lequel :
   un premier champ (120) du préambule fournit une pluralité d’indicateurs
   (142-9) à une pluralité de récepteurs, dans lequel chaque indicateur de la pluralité d’indicateurs indique un ensemble d’une pluralité de séquences d’apprentissage qui correspond à la transmission de l’unité de données à un récepteur correspondant de la pluralité de récepteurs ; et
   le préambule comporte un deuxième champ (VHT PORTION) comportant la pluralité de séquences d’apprentissage (130) ; et
   dans lequel l’unité PHY est configurée en outre pour faire transmettre le premier champ du préambule avant le deuxième champ du préambule transmis.

7. Dispositif selon la revendication 6, dans lequel un premier indicateur de la pluralité d’indicateurs indi-
   que un premier nombre de courants spatiaux ou spatio-temporels qui correspond à la transmission de l’unité de données à un premier récepteur de la pluralité de récepteurs, ou
   dans lequel un premier indicateur de la pluralité d’indicateurs qui correspond à un premier récepteur de la pluralité de récepteurs est un autre indicateur pour un deuxième récepteur de la pluralité de récepteurs qui correspond à la transmission de l’ensemble de la pluralité de séquences d’apprentissage qui correspond à la transmission de l’unité de données au deuxième récepteur.

8. Dispositif selon la revendication 6 ou 7, dans lequel l’unité PHY est configurée en outre pour communi-
   quer à la pluralité de récepteurs, avant la transmission du premier champ du préambule, un ordre dans lequel le premier champ du préambule fournit la plu-
ralité d'indicateurs des ensembles de séquences de la pluralité de séquences d'apprentissage à la pluralité de récepteurs, et/ou dans lequel l'unité PHY est configurée en outre pour inclure un identifiant de groupe correspondant à la pluralité de récepteurs dans un troisième champ du préambule.

9. Procédé de réception de préambule d'une unité de données (100) pour transmission par l'intermédiaire d'un canal de communication à entrées multiples, sorties multiples, MIMO utilisant un premier récepteur, le procédé comprenant :

- la réception d'un premier champ (120) du préambule, dans lequel le premier champ du préambule fournit une pluralité d'indicateurs (142-9), dans lequel chaque indicateur de la pluralité d'indicateurs indique un ensemble d'une pluralité de séquences d'apprentissage qui correspond à la transmission de l'unité de données à un récepteur correspondant d'une pluralité de récepteurs, dans lequel le premier récepteur est un récepteur de la pluralité de récepteurs ;
- la détermination du fait qu'un premier ensemble de la pluralité de séquences d'apprentissage correspond au premier récepteur en se basant sur l'indicateur de la pluralité d'indicateurs qui correspond au premier récepteur ;
- la réception d'un deuxième champ (VHT PORTION) du préambule après la réception du premier champ du préambule, dans lequel le deuxième champ du préambule comprend la pluralité de séquences d'apprentissage (130) ; et
- l'utilisation du premier ensemble de la pluralité de séquences d'apprentissage pour générer une estimation d'au moins une partie du canal de communication MIMO.

10. Procédé selon la revendication 9, dans lequel l'indicateur qui correspond au premier récepteur indique un premier nombre de courants spatiaux ou spatio-temporels qui correspond à la transmission de l'unité de données au premier récepteur.

11. Procédé selon la revendication 9 ou 10, dans lequel la détermination du fait que le premier ensemble de la pluralité de séquences d'apprentissage correspond au premier récepteur est basée en outre sur un deuxième indicateur de la pluralité d'indicateurs qui correspond à un deuxième récepteur de la pluralité de récepteurs.

12. Procédé selon l'une quelconque des revendications 9 à 11, comprenant en outre :

- la réception d'une indication d'un ordre dans lequel le premier champ du préambule fournit la pluralité d'indicateurs des ensembles de séquences de la pluralité de séquences d'apprentissage à la pluralité de récepteurs, avant la réception du premier champ du préambule ; et
- la détermination du fait que le premier ensemble de la pluralité de séquences d'apprentissage correspond au premier récepteur en se basant en outre sur l'indication de l'ordre.

13. Procédé selon l'une quelconque des revendications 9 à 12, comprenant en outre :

- la réception d'un troisième champ du préambule, dans lequel le troisième champ du préambule comporte un identifiant de groupe correspondant à la pluralité de récepteurs ; et
- la détermination du fait que le premier ensemble de la pluralité de séquences d'apprentissage correspond au premier récepteur en se basant en outre sur l'identifiant de groupe.

14. Dispositif (25) comprenant :

- une unité de couche physique PHY (29) configurée pour :

  - recevoir un premier champ (120) d'un préambule d'une unité de données par l'intermédiaire d'un canal de communication à entrées multiples, sorties multiples, MIMO, dans lequel le premier champ du préambule fournit une pluralité d'indicateurs (142-9), dans lequel chaque indicateur de la pluralité d'indicateurs indique un ensemble d'une pluralité de séquences d'apprentissage qui correspond à la transmission de l'unité de données à un récepteur correspondant d'une pluralité de récepteurs, et dans lequel un premier récepteur de la pluralité de récepteurs comprend le dispositif ;
  - déterminer qu'un premier ensemble de la pluralité de séquences d'apprentissage correspond au premier récepteur en se basant sur l'indicateur de la pluralité d'indicateurs qui correspond au premier récepteur ;
  - recevoir un deuxième champ (VHT PORTION) du préambule après la réception du premier champ du préambule, dans lequel le deuxième champ du préambule comprend la pluralité de séquences d'apprentissage (130) ; et
  - utiliser le premier ensemble de la pluralité de séquences d'apprentissage pour générer une estimation d'au moins une partie du canal de communication MIMO.

15. Dispositif selon la revendication 14, dans lequel l'in-
dicateur qui correspond au premier récepteur indique un premier nombre de courants spatiaux ou spatio-temporels qui correspond à la transmission de l’unité de données au premier récepteur, et/ou dans lequel l’unité PHY est configurée en outre pour recevoir une indication d’un ordre dans lequel le premier champ du préambule fournit la pluralité d’indicateurs des ensembles de la pluralité de séquences d’apprentissage à la pluralité de récepteurs, avant de recevoir le premier champ du préambule, et déterminer que le premier ensemble de la pluralité de séquences d’apprentissage correspond au premier récepteur en se basant en outre sur l’indication de l’ordre, et/ou dans lequel l’unité PHY est configurée en outre pour recevoir un troisième champ du préambule, dans lequel le troisième champ du préambule comporte un identifiant de groupe correspondant à la pluralité de récepteurs, et déterminer que le premier ensemble de la pluralité de séquences d’apprentissage correspond au premier récepteur en se basant en outre sur l’identifiant de groupe.

FIG. 18

400

402
INCLUDE INDICATION OF FIRST NUMBER OF STREAMS IN FIRST FIELD

404
INCLUDE ONE OR MORE TRAINING SEQUENCES IN SECOND FIELD

406
FORMAT SUCH THAT FIRST FIELD WILL BE TRANSMITTED PRIOR TO SECOND FIELD
FIG. 19

500

502
RECEIVE FIRST FIELD WITH INDICATION OF FIRST NUMBER OF STREAMS

504
DETERMINE THAT FIRST SET OF ONE OR MORE TRAINING SEQUENCES CORRESPONDS TO FIRST RECEIVER

506
RECEIVE ONE OR MORE TRAINING SEQUENCES

508
UTILIZE FIRST SET OF ONE OR MORE TRAINING SEQUENCES TO GENERATE CHANNEL ESTIMATE
FIG. 20

600

602
GENERATE FIRST FIELD WITH INDICATORS OF SETS OF TRAINING SEQUENCES

604
INCLUDE TRAINING SEQUENCES IN SECOND FIELD

606
FORMAT SUCH THAT FIRST FIELD WILL BE TRANSMITTED PRIOR TO SECOND FIELD
**FIG. 21**

700

702 RECEIVE FIRST FIELD WITH INDICATORS OF SETS OF TRAINING SEQUENCES

704 DETERMINE THAT FIRST SET OF TRAINING SEQUENCES CORRESPONDS TO FIRST RECEIVER

706 RECEIVE SECOND FIELD WITH TRAINING SEQUENCES

708 UTILIZE FIRST SET OF TRAINING SEQUENCES TO GENERATE CHANNEL ESTIMATE
