Methods and compositions inhibiting a lysyl oxidase (-like) protein for treatment and diagnosis of fibrosis, tumor invasion, angiogenesis, and metastasis

The present disclosure provides innovative methodology and related compositions and kits for preventing and treating various diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, by using an inhibitor of processed forms of lysyl oxidase or lysyl oxidase-like proteins, an inhibitor of LOX and an inhibitor of a LOXL, or a synergistic combination of an inhibitor of LOX or LOXL combined with other therapeutic agents. Also provided are innovative methods for selecting agents that prevent or inhibit tumor invasion, angiogenesis and metastasis, by contacting cells that are in an epithelial-mesenchymal transition (EMT) state with a candidate agent and detecting a change in the EMT state of the cells. Methods and related compositions and kits for diagnosing or monitoring various diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, by using molecules or agents that specifically recognize processed forms of LOX or LOXL are also provided. Also provided herein are methods and related compositions, medical devices, systems and kits for preventing or treating various diseases and conditions associated with fibrosis with compositions comprising inhibitors of LOX or LOXL. Such diseases or conditions include pathological cardiovascular conditions and diseases such as hypertension, hypertensive heart disease, myocardial infarction, atherosclerosis, and restenosis, liver fibrosis, kidney fibrosis, lung fibrosis, dermal scaring, keloid formation, and Alzheimer’s disease.

BACKGROUND

1. Cancer

[0002] Cancer is a serious public health problem in the United States and other developed countries. Currently, one in four deaths in the United States is due to cancer. Cancer therapy involves treating patients with chemotherapeutic drugs to kill tumor cells. However, subsets of tumor cells are frequently resistant to drug therapy and survive to repopulate at sites of origin and at distant metastatic sites, leading to detectable disease recurrence and morbidity. Many carcinoma tumor cells that have the properties of increased invasive and metastatic capacity, and altered drug resistance, are thought to have undergone a morphological transformation encompassing or similar to EMT (epithelial-mesenchymal transition). Cells undergoing EMT lose the normal adhesive properties of epithelial cells and undergo a spectrum of changes including loss of E-cadherin expression and expression of mesenchymal markers, increased motility, increased invasiveness, and increased resistance to cell death.

[0003] The leading therapies for cancer are currently surgery, radiation and chemotherapy. Chemotherapeutic approaches such as antitumor antibiotics, alkylating agents, nitrosourea compounds, vinca alkaloids, steroid hormones, and anti-metabolites form the bulk of therapies available to oncologists. Despite advances in the field of cancer treatment, cancer remains a major health problem.

2. Angiogenesis

[0004] Angiogenesis, the formation of new blood vessels out of pre-existing capillaries, is a sequence of events that is of key importance in a broad array of physiologic and pathologic processes. Normal tissue growth, such as in embryonic development, wound healing, and the menstrual cycle, is characterized by dependence on new vessel formation for the supply of oxygen and nutrients as well as removal of waste products. A large number of different and unrelated diseases are also associated with formation of new vasculature. Among certain pathologies are conditions in which angiogenesis is low, and should be enhanced to improve disease conditions. More frequently, however, excessive angiogenesis is an important characteristic of various pathologies, including pathologies characterized or associated with an abnormal or uncontrolled proliferation of cells. Pathologies which involve excessive angiogenesis include, for example, cancer (both solid and hematologic tumors), cardiovascular diseases (such as atherosclerosis and restenosis), chronic inflammation (rheumatoid arthritis, Crohn’s disease), diabetes (diabetic retinopathy), psoriasis, endometriosis, neovascular glaucoma and adiposity. These conditions may benefit from chemotherapeutic inhibition of angiogenesis.

[0005] Generally speaking, the angiogenic process entails the proliferation and migration of a normally quiescent endothelium, the controlled proteolysis of the pericellular matrix, and the synthesis of new extracellular matrix components by developing capillaries. The establishment of new intra- and intercellular contacts and the morphological differentiation of endothelial cells to capillary-like tubular networks provide support for their subsequent maturation, branching, remodeling and selective regression to form a highly organized, functional microvascular network. The autocrine, paracrine and amphicrine interactions of the vascular endothelium with its surrounding stromal components, as well as with the pro-angiogenic and angiostatic cytokines and growth factors orchestrating physiologic angiogenesis, are normally tightly regulated both spatially and temporally.

[0006] Angiogenesis is crucial to the growth of neoplastic tissues. For more than 100 years, tumors have been observed
to be more vascular than normal tissues. Several experimental studies have suggested that both primary tumor growth and metastasis require neovascularization. In contrast to the well orchestrated process described above for normal tissue growth, the pathologic angiogenesis necessary for active tumor growth is generally sustained and persistent, with the initial acquisition of the angiogenic phenotype being a common mechanism for the development of a variety of solid and hematopoietic tumor types. Tumors that are unable to recruit and sustain a vascular network typically remain dormant as asymptomatic lesions in situ. Metastasis is also angiogenesis-dependent: for a tumor cell to metastasize successfully, it generally gains access to the vasculature in the primary tumor, survives the circulation, arrest in the microvasculature of the target organ, exit from this vasculature, grow in the target organ, and induce angiogenesis at the target site. Thus, angiogenesis appears to be necessary at the beginning as well as the completion of the metastatic cascade.

[0007] The criticality of angiogenesis to the growth and metastasis of neoplasms thus provides an optimal potential target for chemotherapeutic efforts. Appropriate anti-angiogenic agents may act directly or indirectly to influence tumor-associated angiogenesis either by delaying its onset (i.e., blocking an "angiogenic switch") or by blocking the sustained and focal neovascularization that is characteristic of many tumor types. Anti-angiogenesis therapies directed against the tumor-associated endothelium and the multiple molecular and cellular processes and targets implicated in sustained pathologic angiogenesis are being actively evaluated for their safety and efficacy in multiple clinical trials. However, there has been limited success to date with the discovery and/or identification of safe and/or effective anti-angiogenic agents.

3. Fibrosis

[0008] Fibrosis is the abnormal accumulation of fibrous tissue that can occur as a part of the wound-healing process in damaged tissue. Such tissue damage may result from physical injury, inflammation, infection, exposure to toxins, and other causes. Examples of fibrosis include dermal scar formation, keloids, liver fibrosis, lung fibrosis (e.g., silicosis, asbestosis), kidney fibrosis (including diabetic nephropathy), scleroderma, and glomerulosclerosis.

[0009] Liver (hepatic) fibrosis, for example, occurs as a part of the wound-healing response to chronic liver injury. Fibrosis occurs as a complication of haemochromatosis, Wilson’s disease, alcoholism, schistosomiasis, viral hepatitis, bile duct obstruction, exposure to toxins, and metabolic disorders. This formation of scar tissue is believed to represent an attempt by the body to encapsulate the injured tissue. Liver fibrosis is characterized by the accumulation of extracellular matrix that can be distinguished qualitatively from that in normal liver. Left unchecked, hepatic fibrosis progresses to cirrhosis (defined by the presence of encapsulated nodules), liver failure, and death.

[0010] As summarized by Li and Friedman (Gastroenterol. Hepatol. 14: 618-633, 1999), actual and proposed therapeutic strategies for liver fibrosis include removal of the underlying cause (e.g., toxin or infectious agent), suppression of inflammation (using, e.g., corticosteroids, IL-1 receptor antagonists, or other agents), down-regulation of stellate cell activation using, e.g., gamma interferon or antioxidants), promotion of matrix degradation, or promotion of stellate cell apoptosis. Despite recent progress, many of these strategies are still in the experimental stage, and existing therapies are aimed at suppressing inflammation rather than addressing the underlying biochemical processes. Thus, there remains a need in the art for materials and methods for treating fibrosis, including liver and lung fibrosis.

[0011] There is a need in the art for improved methods for treating cancer, diseases associated with abnormal or undesirable angiogenesis and fibrosis. The present disclosure addresses this need and provides related advantages.

SUMMARY

I. Treatment by Inhibiting Processed LOX or LOXL

[0012] The present disclosure provides innovative methodology and related compositions and kits for preventing and treating various diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, by using an inhibitor of lysyl oxidase (LOX) or lysyl oxidase-like protein(s) (LOXL). The LOX or LOXL may be a full-length or processed form. The full-length LOX or LOXL is a proenzyme or propeptide form (i.e. without the signal sequence) whereas the processed form, or cleavage form is a mature form. Both full-length and processed forms of LOX or LOXL can be active. The LOX or LOXL can be a secreted form, which can also be active. The inhibition of LOX or LOXL is effective in preventing and controlling tumor invasion and metastasis, and for treating diseases associated with abnormal angiogenesis and fibrotic diseases.

[0013] In one embodiment, methods are provided for treating or preventing tumor invasion or metastasis in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of active LOX or LOXL.

[0014] In another embodiment, methods are provided for reducing tumor growth in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of processed LOX or LOXL such that the tumor growth is reduced by at least 25%, 50%, 75%, 90%, or 95%. In some embodiments, the tumor is a metastatic tumor.

[0015] In yet another embodiment, methods are provided for increasing or enhancing the chances of survival of a
subject with metastatic tumor, comprising: administering to a subject in need thereof an effective amount of an inhibitor of processed LOX or LOXL protein, thereby increasing or enhancing the chances of survival of the subject treated by a certain period of time. For example, the survival of the subject may be increased by at least 10 days, 1 month, 3 months, 6 months, 1 year, 1.5 years, 2 years, 3 years, 4 years, 5 years, 8 years, or even 10 years.

The LOX or LOXL may be a mature form of the LOX or LOXL after proteolytic processing or cleavage. Examples of LOXL include but are not limited to LOXL1, LOXL2, LOXL3, and LOXL4. In some embodiments, the inhibitor of LOX or LOXL may be an inhibitor of active LOX, LOXL2 or LOXL4. In some of these embodiments, the inhibitor of LOX or LOXL inhibits both active LOX and LOXL2.

The LOX or LOXL inhibitor may be, for example, an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL. The inhibitors may be noncompetitive inhibitors.

II. Treatment by Inhibition of Both LOX and LOXL

The present disclosure also provides innovative methodology and related compositions and kits for preventing and treating various diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, through inhibition of both lysyl oxidase (LOX) and one or more lysyl oxidase-like proteins (LOXL). Simultaneous inhibition of both LOX and LOXL is effective in preventing or treating invasion and metastasis of a wide variety of tumors, and for treating diseases associated with abnormal angiogenesis and fibrotic diseases.

In one embodiment, methods are provided for treating or preventing tumor invasion or metastasis in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of LOX and an inhibitor of LOXL.

In another embodiment, methods are provided for reducing tumor growth in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of LOX and an inhibitor of a LOXL such that the tumor growth is reduced by at least 25%, 50%, 75%, 90%, or even 95%. According to some embodiments, the tumor is a metastatic tumor.

In yet another embodiment, methods are provided for increasing or enhancing the chances of survival of a subject with a metastatic tumor, comprising: administering to a subject in need thereof an effective amount of an inhibitor of LOX and an inhibitor of a LOXL, thereby increasing or enhancing the chances of survival of the subject treated by a certain period of time. For example, the survival of the subject is increased by at least 10 days, 1 month, 3 months, 6 months, 1 year, 1.5 years, 2 years, 3 years, 4 years, 5 years, 8 years, or even 10 years.

The inhibitor of LOX and the inhibitor of the LOXL can be different, each specifically inhibiting LOX and LOXL, respectively. Alternatively, the inhibitor of LOX and the inhibitor of LOXL can be the same molecule which inhibits both LOX and LOXL. The LOXL may be, for example, LOXL1, 2, 3, or 4. In some embodiments, the LOXL is LOXL2 or 4. In certain embodiments, the LOXL is LOXL2.

The LOX or LOXL may be a full-length or processed form. The LOX or LOXL may be a proenzyme form or a mature form, and both forms can be active. The LOX or LOXL can be a secreted form, which can also be active. The processed form of the LOX or LOXL is a form after proteolytic processing or cleavage.

Examples of LOXL include but are not limited to LOXL1, LOXL2, LOXL3, and LOXL4. In some embodiments, the inhibitor of LOX or LOXL may be an inhibitor of active LOX, LOXL2 or LOXL4. In some of these embodiments, the inhibitor of LOX or LOXL inhibits both active LOX and LOXL2.

The LOX or LOXL inhibitor may be, for example, an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL. The inhibitors may be noncompetitive inhibitors.

III. Combination Therapy

The present disclosure further provides compositions, kits, methods for preventing and treating diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, such as cancer, tumors, diabetic retinopathy, macular degeneration, liver fibrosis, kidney fibrosis, lung fibrosis, scleroderma, atherosclerosis, and Alzheimer’s disease by using modulators (e.g., activators/agonists or inhibitors/antagonists) of lysyl oxidase (LOX) or lysyl oxidase-like proteins (LOXL). Simultaneous inhibition of both LOX and LOXL is effective in preventing or treating invasion and metastasis of a wide variety of tumors, and for treating diseases associated with abnormal angiogenesis and fibrotic diseases.

Inhibitors of LOX or LOXL may be combined with other therapeutic agents, such as chemotherapeutic agents, anti-neoplastic biologics, anti-angiogenic agents, and anti-fibrotic agents, to prevent or treat these diseases or conditions. It is believed that inhibition of LOX or LOXL could slow or halt the progression of the epithelial-mesenchymal transition (EMT) in tumor cells, or induce a mesenchymal-epithelial transition (MET) to a less tumorigenic state, thereby rendering the tumor or diseased cells more susceptible to chemotherapeutic drugs, anti-neoplastic biologics, anti-angiogenic agents, and anti-fibrotic agents. A synergistic combination of an inhibitor of LOX or LOXL with another therapeutic agent is useful for preventing or inhibiting tumor invasion and metastasis, inhibiting growth of primary tumors by sensitizing the tumor cells to the cytotoxic effects of the therapeutic agent, and also for efficaciously prevention or treatment of cancer.
IV. Selection of Agents

[0028] In another aspect, the present disclosure provides innovative methods for selecting agents that prevent or inhibit tumor invasion, angiogenesis and metastasis. According to the present disclosure, inhibition of lysyl oxidase (LOX) or lysyl oxidase-like protein (LOXL) may slow or halt the progression of the epithelial-mesenchymal transition (EMT) in tumor cells, or induce a mesenchymal-epithelial transition (MET) to a less tumorigenic state, thereby preventing or inhibiting the invasion, angiogenesis and metastasis of the tumor, and rendering the primary tumor cells more susceptible to other therapeutic intervention, such as irradiation, chemotherapeutic drugs, anti-neoplastic biologics, anti-angiogenic agents, and anti-fibrotic agents.

[0029] In one embodiment, methods are provided for selecting an inhibitor of tumor invasion, angiogenesis or metastasis, comprising: contacting cells that are in an EMT state with an inhibitor of LOX or a LOXL; detecting a change in the EMT state of the cells, wherein reduction of the EMT state or a shift from the EMT to a MET state indicates that the LOX or LOXL inhibitor is an inhibitor of tumor invasion, angiogenesis or metastasis.

V. Diagnosis

[0030] In yet another aspect, the present disclosure provides innovative methodology and related compositions and kits for diagnosing or monitoring various diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, by using molecules or agents that specifically recognize active or mature forms of lysyl oxidase or lysyl oxidase-like proteins. The inventors believe the processed LOX or LOXL are important biomarkers for tumor invasion and metastasis, and for diseases associated with abnormal angiogenesis and fibrotic diseases. The processed forms of LOX or LOXL can inhibit tumor invasion, angiogenesis and metastasis. According to the present disclosure, inhibition of lysyl oxidase or lysyl oxidase-like proteins has a therapeutic effect on the subject. The change may be an increase or a decrease in processed LOX or LOXL levels or activity.

[0031] In one embodiment, methods are provided for diagnosing or monitoring cancer metastasis in a subject, comprising: assessing processed LOX or LOXL levels or activity in the blood or in a tumor, whereby a change in processed LOX or LOXL levels or activity in the blood or in the tumor in comparison with a reference sample indicates the presence of metastatic tumor growth. The change may be an increase or a decrease in processed LOX or LOXL levels or activity. Generally, an increase in processed LOX or LOXL levels or activity in the blood or tumor sample, as compared to a reference sample, indicates the presence of metastatic tumor growth.

[0032] In another embodiment, methods are provided for monitoring a subject’s response to a therapy including a modulator of LOX/LOXL such as the treatment of cancer, tumors, angiogenesis, and fibrotic diseases. In another embodiment, the method comprises: detecting a change in the level of collagen telopeptides or hydroxyproline content in the subject after administration of a modulator of LOX or LOXL to the subject, wherein the change indicates that the LOX or LOXL modulator has a therapeutic effect on the subject. The change can be an increase or decrease. For example, a decrease in collagen telopeptides or hydroxyproline content can be indicative of a therapeutic effect.

[0033] The method comprises detecting a change in the level C-reactive protein, or other acute-phase reactants, in the subject after administration of a modulator of LOX or LOXL to the subject, wherein the change indicates that the LOX or LOXL modulator has a therapeutic effect on the subject. The change may be an increase or a decrease in C-reactive protein levels. Generally, a decrease in C-reactive protein levels indicates a decrease in LOX activity.

VI. Treatment of Fibrosis

[0034] In another aspect, methods are provided for preventing, treating, or ameliorating fibrosis in a subject in vivo, comprising administering to the subject an effective amount of an inhibitor of a lysyl oxidase (LOX) or lysyl oxidase-like protein (LOXL). The inhibitor of LOX or LOXL may be an inhibitor of an active form of LOX or LOXL.

[0035] Exemplary forms of fibrosis include, but are not limited to, cardiac fibrosis, liver fibrosis, kidney fibrosis, lung fibrosis, dermal scarring and keloids, and Alzheimer’s disease. In still further embodiments, cardiac fibrosis is associated with hypertension, hypertensive heart disease (HHD), myocardial infarction (MI), atherosclerosis, and restenosis.

[0036] The kidney fibrosis may include, but not be limited to, diabetic nephropathy, vesicoureteral reflux, tubulointerstitial renal fibrosis, glomerulonephritis or glomerular nephritis (GN), focal segmental glomerulosclerosis, membranous glomerulonephritis, or mesangiocapillary GN. The liver fibrosis may include, but not be limited to, cirrhosis, and associated conditions such as chronic viral hepatitis, non-alcoholic fatty liver disease (NAFLD), alcoholic steatohepatitis (ASH), non-alcoholic steatohepatitis (NASH), primary biliary cirrhosis (PBC), biliary cirrhosis, autoimmune hepatitis. Lung fibrosis may include idiopathic pulmonary fibrosis (IPF) or cryptogenic fibrosing alveolitis, chronic fibrosing interstitial pneumonia, interstitial lung disease (ILD), and diffuse parenchymal lung disease (DPLD)). Cardiac fibrosis, congestive heart failure, cardiomyopathy, post-myocardial infarction defects in heart function; atherosclerosis; rheumatoid arthritis; glaucoma; age-related macular degeneration (wet AMD and dry AMD); emphysema, chronic obstructive pulmonary disease (COPD); multiple sclerosis; and chronic asthma may also be prevented, treated, or ameliorated with compositions
of described herein.

[0037] Also provided herein are compositions, devices, systems, and kits for delivering inhibitors of LOX/LOXL locally to the site of fibrosis. Medical devices such as catheters and stents may be used to deliver locally, thus substantially reducing the risk of toxicity or other side effects associated with systemic delivery of such inhibitors of LOX/LOXL.

[0038] The inhibitors of LOX/LOXL may be delivered to a subject prior to, concurrently, or post a pathological cardiac condition or disease, such as hypertension, hypertensive heart disease (HHD), myocardial infarction (MI), atherosclerosis, and restenosis, to prevent the onset of, to reduce the risk of, or to retreat pathological fibrosis associated with such a pathological cardiac condition or disease. For example, an inhibitor of LOX/LOXL may be administered at least 1 hr, 2 hrs, 3 hrs, 5 hrs, or 10 hrs, or 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14 or more days after the onset of such a pathological cardiac condition or disease.

[0039] The LOX or LOXL may be a full-length or processed form. The LOX or LOXL may be a proenzyme form or a mature form, and both forms can be active. The LOX or LOXL can be a secreted form, which can also be active. The processed form of the LOX or LOXL is a form after proteolytic processing or cleavage.

[0040] Examples of LOXL include but are not limited to LOXL1, LOXL2, LOXL3, and LOXL4. In some embodiments, the inhibitor of LOX or LOXL may be an inhibitor of active LOX, LOXL2 or LOXL4. In some of these embodiments, the inhibitor of LOX or LOXL inhibits both active LOX and LOXL2.

[0041] The LOX or LOXL inhibitor may be, for example, an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL. The inhibitors may be noncompetitive inhibitors.

BRIEF DESCRIPTION OF THE DRAWINGS

[0042] FIGURE 1 is a schematic of the LOX/LOXL genomic and protein organization.

FIGURE 2 is a sequence alignment of LOX/LOXL with predicted and determined N- and O-glycosylation sites, bipartite nuclear localization signals, and procollagen C-protease sites.

FIGURE 3 illustrates the epithelial-mesenchymal transition and its role in invasion and metastasis.

FIGURE 4 is a schematic of the EMT and MET and markers for to assess EMT or MET phenotypes of cells.

FIGURE 5 is a schematic of the role of LOX/LOXL in EMT-MET promotion or reduction, and the drug-resistance or sensitivity of the EMT-MET cells.

FIGURE 6 shows induction of EMT by transfection of MCF-7 (low LOXL2) cells with LOXL2. (A) MCF-7 wild type (WT) cells and (B) MCF-7-Lox12.clone1 were stained for E-cadherin. Primary antibody: anti-E-cadherin (10μg/ml); Secondary antibody: anti-mouse-cy3 (red); DAPI: nuclei (blue). (C) MCF-7 wild type cells and (D) MCF-7-Lox12.clone1 were stained with rhodamine phalloidin: actin cytoskeleton (red) and DAPI: nuclei (blue). Wild-type MCF7 shows epithelial phenotype, strongly E-cadherin positive (membrane staining) (A) and rhodamine phalloidin staining of the actin cytoskeleton reveals a circular pattern (C). MCF7 transfected with LOXL2 changes to a mesenchymal phenotype, losing E-cadherin expression (B), with remodeling of the actin cytoskeleton (elongation, spindly shaped, long actin fibers) (D).

FIGURE 7 shows induction of MET-like change by depleting LOXL2 in MDA-MB-231. (A-B) MDA-MB-231 WT cells and (C-F) MDA-MB-231 shLox12 (C, D): pool 1; (E, F): pool 2) stable knockdown cells were stained with rhodamine phalloidin (actin cytoskeleton stain). Cells are elongated and spindly-shaped in WT cells (A-B) while MDA-MB-231 shLox12 stable knockdown cells are rounded and smaller in shape (C-F). F-actin staining (rhodamine phalloidin) moves from fibrillar to circular / cell rim upon LOXL2 depletion by shRNA knockdown.

FIGURE 8 shows the effects of Conditioned Media (CM) derived from stable CHO-Lox12 cells on MCF-7 WT cells. (A-B) MCF-7 cells grown in 30% SFII media: 150μl of SFII media (media used for CHO-Lox12) in 350μl of regular MCF-7 complete media. (C-D) MCF-7 cells grown in 30% Conditioned Media (CM): 150μl of CM from CHO-Lox12 (concentrated 22X from 3 day serum free CM) in 350μl of regular MCF-7 complete media. The MCF-7 cells treated with concentrated serum free CM from CHO-Lox12 cells for 4 days. MCF-7 treated with conditioned media from LOXL2-expressing cells (C-D) undergoes a phenotype change compared to cells treated with control conditioned media (CHO cells not expressing LOXL2) (A-B), as revealed by rhodamine-phalloidin staining of the actin cytoskeleton. Cells are elongated with long F-actin fibers, similar to cells undergoing EMT, unlike control-treated cells that show a more circular "actin rim" staining. These data support that the EMT-like change induced by LOXL2 is induced by secreted (extracellular) LOXL2. (E) illustrates effects of different concentrations of CM derived from stable CHO-Lox12 cells on MCF-7 WT cells and their morphological changes. Treating cells with increasing concentrations of LOXL2-containing CM results in a concordant increase in EMT-like phenotype change.

FIGURE 9 shows anti-Lox12 mAbs can block the EMT phenotype observed from incubating MBA-MD-MB-231 (expresses high levels of LOXL2) CM with MCF-7 WT cells. (A, C, E) MCF-7 WT cells with CM from MCF-7 cells and (B, D, F) MCF-7 WT cells with CM from MBA-MD-MB-231 cells, with (C-F) showing cells with CM that was pre-
incubated with anti-Lox12 mAbs prior to addition to MCF-7 cells (C, D): mAb #418 and (E, F): mAb #423, respectively), with varying concentration of antibody (C, E): 2 μg; (D, F): 4 μg).

**FIGURE 10** demonstrates that the specific blocking effect of the EMT-like change from incubating MDA-MB-231 CM with MCF-7 cells. (A) "Pre-incubation": CM, collected and cleared, was pre-incubated with anti-Lox12 (1.5 hrs at room temperature (RT)) #418 or #422 mAb, then applied onto MCF-7 cells for 4 days. (B) "Not pre-incubated": CM with MDA-MB-231 cells was in the presence of anti-Lox12 #418 or #422 mAb (3 days) and before being collected and cleared, then applied onto MCF-7 for 4 days. EMT-like morphology is blocked in both (A) and (B). As a non-EMT-like control, (C) MCF-7 cells treated with 3 day Conditioned Media (CM) from MCF-7 cells for 4 days and had a round and flattened morphology that is typical of WT MCF-7 cells. As EMT-like controls, (D) MCF-7 cells treated with 3 day CM from MDA231 cells that was not incubated with any lox12 mAbs (4 day incubation) and (E) MCF-7 cells treated with 3 day CM from MDA231 cells that was pre-incubated with an anti-actin antibody (4 day incubation). Both (D) and (E), an EMT-like morphology of spindly shaped cells is seen.

**FIGURE 11** shows the induction of an EMT-like phenotype change by treating MCF-7 (low LOXL2) with conditioned media from Hs578t tumor cells (expresses high levels of LOXL2) and anti-Lox12 mAbs can block the EMT phenotype observed. (A) Conditioned media from 3 day Conditioned Media (CM) from MCF-7 cells was applied to MCF-7 cells for 4 days and had a round and flattened morphology that is typical of WT MCF-7 cells. (B, C, D) Conditioned media from Hs-578t cells (LOXL2 high) was applied to MCF-7 cells (LOXL2 low/negative). (A-D) Cells stained with rhodamine-phalloidin (F-actin, red) and DAPI (nuclei, blue). Confirming that these effects are specific to LOXL2 and not other proteins, conditioned media was mixed with 4 μg of either (C) anti β-actin antibody as a negative control or (D) anti LOXL2 antibody. EMT-like phenotype was blocked when the conditioned media from Hs578t cells was pre-incubated with an anti-LOXL2 antibody prior to addition to MCF7 cells (D). Treating the CM in the same manner with an anti β-actin antibody failed to block the phenotype change in the MCF7 cells (C), supporting that the blockade by the LOXL2 antibody was specific and not a non-specific effect due to addition of antibody to CM.

**FIGURE 12** shows SW620 cells incubated with Conditioned Media (CM) from MDA MB 231 cells undergo EMT phenotype changes. (A-B) SW620 cells are incubated with Conditioned Media (CM) from MDA MB 231 cells, at 20X and 40X. Arrows indicate morphology of SW620 cells undergoing EMT-like phenotype. Cells undergo EMT phenotype (as indicated by rhodamine phalloidin staining) changes 72 hours later. (C-D) SW620 cells incubated with Conditioned Media (CM) from 293 wildtype cells maintain typical "normal" round shape -72 hours later, at 20X and 40X. Conditioned media (CM) from MDA MB 231 or 293 cells is 3 day CM.

**FIGURE 13** shows SW620 cells incubated with CM from 293:Lox12.MCD transfectants. (A, C, E) shows cells undergoing EMT phenotype (as indicated by rhodamine phalloidin staining) changes -72 hours later (50% CM: 50% compete media). (B, C, E) are magnifications of (A, C, E), respectively, with arrows indicating the morphology of SW620 cells undergoing EMT-like phenotype. The 293:Lox12.MCD were 293 cells transfected with and expressing a fragment of LOXL2, referred to as the LOXL2-MCD, which includes the lysyl oxidase enzymatic domain. It appears that this portion of LOXL2 is alone sufficient to induce at least a partial EMT-like phenotype change. Not all cells are undergoing the phenotype change, but groups of cells that are, are clearly distinguished.

**FIGURE 14** is a schematic of (A) uncleaved and intracellular LOX/LOXL and cleaved, active LOX/LOXL and (B) active LOX/LOXL cellular uptake and activity promotes EMT, while uptake of active LOX/LOXL is blocked when bound to an inhibitor such as an antibody, reducing EMT and/or increasing MET.

**FIGURE 15** is a graph showing surface-associated LOX activity in 3T3 cells is inhibited by BAPN, LOX mAb, and LOX siRNA. Specific LOX activity is evident on the cell surface of 3T3 cells quantitated with a horseradish peroxidase-coupled fluorescent assay method based on the oxidation of Amplex Ultra Red with a 1,5-diaminopentane substrate. LOX activity was inhibited with the irreversible small molecule inhibitor BAPN, with a monoclonal antibody raised against a LOX peptide, and with a siRNA oligonucleotide specifically targeting LOX mRNA.

**FIGURE 16** shows 2 forms of LOXL2 predominate in cell lines. (A) LOXL2 protein expression and secretion in cell lines. Breast tumor cell lines: Hs578t, MDA-MB-231, MCF7; Lung tumor cell line: A549. (B) Schematic of LOXL2 forms commonly detected.

**FIGURE 17** shows LOXL2 protein expression purified from CHO cells. Myc-His tagged (C-terminal) LOXL2 was expressed in CHO cells. 2 forms predominate (as in **FIGURE 16**): propeptide LOXL2 and LOXL2 cleaved between SRCR2 and SRCR3. LOXL2 is also secreted in CHO cells.

**FIGURE 18** shows separation of LOXL2 species by chromatography. (A) A chromatograph of the separated LOXL2 species. (B) A Western blot analysis confirming separation of the LOXL2 species.

**FIGURE 19** shows an in vitro enzymatic assay that indicates that both forms of LOXL2 are active.

**FIGURE 20** is an IC50 graph for LOXL2. Inhibition of LOXL2 was performed in an in vitro enzymatic assay using active LOXL2 and a LOXL2 antibody, AB0023. M1 and M20 are both AB0023. Asc = ascites generated, unlabeled = bioreactor generated, same results. Dose response showing decreased activity with increasing concentration of antibody. LOXL2 preparation includes both processed forms (propeptide and mature).

**FIGURE 21** is a graph demonstrating a mode of inhibition of LOXL2. (A) AB0023 is a non-competitive inhibitor of
LOXL2, whereas (B) βAPN is a competitive inhibitor of LOXL2. E = enzyme, P = product, S = substrate, I/A = inhibitor/antibody.

FIGURE 22 shows a minimal catalytic domain region (MCD) of LOXL2 is enzymatically active. (A) is schematic of LOXL2 MCD construction. (B) LOXL2 MCD is secreted efficiently. (C) LOXL2 MCD is enzymatically active.

FIGURE 23 illustrates internalization and uptake for anti-LOX antibody. Immunofluorescence analysis of LOX in live tumor cells was performed using antibodies. (A-B) Hs578T cells were transfected with siNT (non-targeting knockdown control) and incubated for 3 hours with mAbs. LOx was localized in the cytosol. (C-D) Hs578T cells were incubated for 3 hours with mAbs transfected with siLOX. LOX protein levels were diminished, supporting depletion by siLOX. LOX protein was also periplasmic in the cell. LOX was detected with M37 (A, C) or M64 antibody (B, D). Similar results of internalization and uptake of LOX12 mAbs was obtained. Thus, the results support conclusions that staining is specific for LOX or LOXL2.

FIGURE 24 shows confluent Hs578T and anti-LOX antibody internalization and uptake of (A) permeabilized or (B) non-permeabilized cells. Cells were 2 days post-confluent, 4 days after plating at 50,000 cells/well in 8 chamber slides. Cells were incubated for 3 hours with anti-Lox M64 and detected with Alexa 488-green. Similar results of internalization and uptake of Lox12 mAbs was obtained.

FIGURE 25 illustrates internalization and uptake for anti-LOX antibody in Hs578T transfected with siRNA and. Hs578T cells were transfected with (A, B) siNT or (C, D) siLOX and incubated with LOX antibody for 5 hours. Images of cells, detected with anti-Lox M64 (A, C) or anti-collagen I (B, D), were taken 7 days post-transfection. Similar results of internalization and uptake of Lox12 mAbs was obtained.

FIGURE 26 shows the specificity of LOX Pep2 M64. mAbs were screened for their ability to inhibit cell invasion and migration through (A) Collagen I and/or (B) Collagen IV matrix. (C) Specificity of M64Mab on Hs578T cells was detected on chamber slides (post-confluent: Day 6). (D) LOX localization compared with collagen Hs578T cells on chamber slides (post-confluent: Day 6). Cells were not permeabilized and images were at 63X magnification.

FIGURE 27 shows a time-course study of Hs578T cells from Day 0 to Day 15 post-confluent.

FIGURE 28 is a graph showing mRNA levels of LOX and LOXL2 overexpressed in tumors and fibrotic disease tissues compared to normal tissues as measured by using RNA chips provided by Affymetrix, Inc.

FIGURE 29 depicts immunohistochemistry (IHC) using LOXL2 and LOX antibodies on normal metastatic breast tumor tissue (lymph node) sample. IHC was performed using breast TMA: CC08-21-002 (Cybrdi), a metastatic nonspecific infiltrating ductal carcinoma sample, with (A, B) LOXL2, (C, D) Ki67, a marker of cell proliferation, and (E, F) LOX. LOXL2 and LOX are both expressed by the tumor cells and there is evidence of expression of both LOXL2 and LOX by stromal cells. (brown staining). (A, C, E) 20X magnification; (B, F) 40X magnification.

FIGURE 30 is a graph showing mRNA levels of lysyl oxidase family members in human cell lines. One-step qRT-PCR was performed on 100ng/rxn RNA. MCF7, MB231, BT549, Hs578t: breast tumor cell lines; A549: lung tumor cell line; HT1080: fibrosarcoma cell line; HFF: fibroblast cell line.

FIGURE 31 is a graph of RT-PCR validation of (A) shRNA and (B) siRNA knockdown of LOX/LOXL2 in FIGURES 36-39. (C) A migration assay using MDA-MB 231 cells transfected with Lox, Lox12, Lox/Lox12 siRNA was also performed. Lox siRNA knockdown inhibits MDA MB 231 cells invasive properties by 52% compared to non-targeting siRNA control. (D) Supporting Taqman data for siRNA knockdown in MDA MB 231 cells shown in (C).

FIGURE 32 is a graph showing LOX/LOXL2 knockdown cell line (shLOXL2.195) showed approximately 7 fold reduction in cell viability. The calculated IC50 was compared to the control line (sh control). The parental cell line is MDA-MB-231. Percent growth (viability) is plotted on the left axis. Erlotinib represents the drug class EGFR inhibitors, including gefitinib.
I. Treatment by Inhibition of LOX or LOXL

The present disclosure provides innovative methodology and related compositions and kits for preventing and treating various diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, by using an inhibitor of processed form of lysyl oxidase (LOX) or lysyl oxidase-like proteins (LOXL).

While not wishing to be bound by theory, inhibition of the processed forms of LOX or LOXL is effective in preventing or treating tumor invasion and metastasis, and for treating diseases associated with abnormal angiogenesis and fibrotic diseases.

In one embodiment, methods are provided for treating or preventing tumor invasion or metastasis in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of a LOX or LOXL.

In another embodiment, methods are provided for reducing tumor growth in a subject comprising: administering to a subject in need thereof an effective amount of an inhibitor of a processed LOX or LOXL such that the tumor growth is reduced by at least 25%, 50%, 75%, 90%, or 95%. According to some embodiments, the tumor may be a metastatic tumor.

In yet another embodiment, methods are provided for increasing or enhancing the chances of survival of a subject with metastatic tumor, comprising: administering to a subject in need thereof an effective amount of an inhibitor of processed LOX or LOXL, thereby increasing or enhancing the chances of survival of the subject treated by a certain period of time. In some embodiments, the survival of the subject is increased by at least 10 days, 1 month, 3 months, 6 months, 1 year, 1.5 years, 2 years, 3 years, 4 years, 5 years, 8 years, or 10 years.

The processed forms of LOX or LOXL can be active. The LOX or LOXL can also be a secreted form, which can also be active. The active LOX or LOXL may be a mature form of the LOX or LOXL after proteolytic processing or cleavage. Examples of LOXL include but are not limited to LOXL1, LOXL2, LOXL3, and LOXL4. In some embodiments, the inhibitor LOX or LOXL is an inhibitor of active LOX, LOXL2, or LOXL4. For example, the inhibitor of LOX or LOXL inhibits both active LOX and active LOXL2.

The LOX or LOXL inhibitor may be an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.

In some embodiments, the LOX or LOXL inhibitor is an antibody specifically binding to a region of LOX or LOXL.
having an amino acid sequence selected from SEQ ID NOs:1-18 as shown in Tables 1 and 2 below.

**II. Treatment by Inhibition of Both LOX and LOXL**

The present disclosure also provides innovative methodology and related compositions and kits for preventing and treating various diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, by using an inhibitor of a processed form of lysyl oxidase (LOX) or lysyl oxidase-like proteins (LOXL).

Simultaneous inhibition of both LOX and LOXL is effective in preventing or treating invasion and metastasis of a wide variety of tumors, and for treating diseases associated with abnormal angiogenesis and fibrotic diseases.

In one embodiment, methods are provided for treating or preventing tumor invasion or metastasis in a subject in vivo, comprising administering to the subject an effective amount of an inhibitor of LOX and an inhibitor of a LOXL.

In another embodiment, methods are provided for reducing tumor growth in a subject in vivo, comprising administering to the subject an effective amount of an inhibitor of LOX and an inhibitor of a LOXL such that the tumor growth is reduced by at least 25%, 50%, 75%, 90%, or 95%. According to some embodiments, the tumor may be metastatic tumor.

In yet another embodiment, methods are provided for increasing or enhancing the chances of survival of a subject with metastatic tumor, comprising administering to a subject in need thereof an effective amount of an inhibitor of LOX and an inhibitor of a LOXL, thereby increasing or enhancing the chances of survival of the subject treated by a certain period of time. In some embodiments, the survival of the subject is increased by at least 10 days, 1 month, 3 months, 6 months, 1 year, 1.5 years, 2 years, 3 years, 4 years, 5 years, 8 years, or 10 years.

The inhibitor of LOX and the inhibitor of the LOXL can be different, each specifically inhibiting LOX and the LOXL, respectively. Alternatively, the inhibitor of LOX and the inhibitor of LOXL can be the same molecule which inhibits both LOX and the LOXL. In some embodiments, the LOXL is LOXL1, 2, 3 or 4. In some of these embodiments, the LOXL is LOXL2 or 4, for example, the LOXL is LOXL2.

Optionally, the inhibitor of LOX or LOXL inhibits a form of the LOX or LOXL after proteolytic processing or cleavage. The LOX or LOXL may be a proenzyme form or a mature form. The LOX or LOXL may be an active form. The full length or processed forms of LOX or LOXL can be active.

Optionally, the inhibitor of LOX or LOXL inhibits a secreted form of the LOX or LOXL.

The LOX or LOXL inhibitor may be an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.

In some embodiments, the LOX or LOXL inhibitor is an antibody specifically binding to a region of LOX or LOXL having an amino acid sequence selected from SEQ ID NOs:1-18 as shown in Tables 1 and 2 below.

As described in more detail below and in the EXAMPLE section, various inhibitors of LOX or LOXL (such as small molecules or antibodies) may be used to inhibit tumor invasion, angiogenesis or metastasis, and for treating cancer, tumors, and diseases associated with abnormal angiogenesis and fibrotic diseases.

**III. Combination Therapy**

The present disclosure also provides innovative methodology and related compositions and kits for preventing and treating various diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, by using a combination therapy including a modulator of lysyl oxidase (LOX) or lysyl oxidase-like proteins (LOXL).

As described in detail below, inhibition of LOX or LOXL could slow or halt the progression of epithelial-mesenchymal transition (EMT) in tumor cells, or induce a mesenchymal-epithelial transition (MET) to a less tumorigenic state, thereby rendering the tumor or diseased cells more susceptible to irradiation, chemotherapeutic drugs, anti-neoplastic biologics, anti-angiogenic agents, and anti-fibrotic agents.

**IV. Selection of Agents**

The present disclosure provides innovative methods for selecting agents that prevent or inhibit tumor invasion, angiogenesis and metastasis. These agents can be used alone or in combination with other therapeutic agents to prevent or treat diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, such as cancer, tumors, diabetic retinopathy, macular degeneration, scleroderma, liver fibrosis, kidney fibrosis, lung fibrosis, scleroderma, atherosclerosis, and Alzheimer’s disease.

According to the present disclosure, methods are provided for selecting an inhibitor of tumor invasion, angiogenesis or metastasis, comprising contacting cells that are in an epithelial-mesenchymal transition (EMT) state with an
inhibitor of lysyl oxidase (LOX) or a lysyl oxidase-like protein (LOXL); detecting a change in the EMT state of the cells, wherein reduction of the EMT state or a shift from the EMT to a MET state indicates that the LOX or LOXL inhibitor is an inhibitor of fibrosis, tumor invasion, angiogenesis or metastasis. Thus, also provided herein are methods for using the EMT-MET assays to screen for LOX/LOXL inhibitors that facilitate the transition from EMT to MET in tumor cells.

While not wishing to be bound by the theory, the role of LOX and LOXL in EMT is associated with uptake of active LOX or LOXL by tumor cells, allowing LOX or LOXL to interact with relevant intracellular cofactors; and inhibition of LOX or LOXL could slow or halt the progression of EMT in tumor cells, or induce a MET to a less tumorigenic state, thereby preventing or inhibiting the invasion, angiogenesis and metastasis of the tumor, and rendering the primary tumor cells more susceptible to other therapeutic intervention, such as irradiation, chemotherapeutic drugs, anti-neoplastic biologics, anti-angiogenic agents, and anti-fibrotic agents.

An EMT state of cells has the characteristics of positive vimentin or fibronectin staining with low levels of E-cadherin staining and an elongated and remodeled actin cytoskeleton as revealed by phalloidin staining of F-actin. Thus, the reduction of the EMT state or a shift from the EMT to a MET state can be monitored by measuring or detecting a decrease in vimentin or fibronectin staining an increase in E-cadherin staining, and/or remodeling of the actin cytoskeleton by phalloidin staining of F-actin.

Optionally, in vitro or in vivo tumor invasion or migration may be used to assess EMT or MET phenotypes of the cells, as increased invasiveness and migratory capacity are associated with EMT. For example, an in vitro wound-healing or scratch assay may be used to monitor the transition from EMT to MET state, as cells in a state of EMT that are more invasive and migratory should fill the scratch more rapidly than less invasive or migratory cells.

As described in more detail below and in the EXAMPLE section, various LOX or LOXL inhibitors (such as small molecules or antibodies) may be tested for their ability to inhibit tumor invasion, angiogenesis or metastasis by using the EMT-MET transition assay. Inhibition of the full length or processed forms of LOX or LOXL are effective in preventing or treating tumor invasion and metastasis. Thus, also provided herein are methods for screening, selecting and designing candidate compounds for inhibition of active forms of LOX or LOXL, and methods for generating antibodies against active forms of LOX or LOXL.

V. Diagnosis

The present disclosure provides innovative methodology and related compositions and kits for diagnosing or monitoring various diseases associated with abnormal cell proliferation, angiogenesis and fibrosis, by using molecules or agents that specifically recognize a processed form of lysyl oxidase (LOX) or lysyl oxidase-like proteins (LOXL). Without being bound by theory, the processed forms of LOX or LOXL are important biomarkers for tumor invasion and metastasis, and for diseases associated with abnormal angiogenesis and fibrotic diseases.

In one embodiment, methods are provided for diagnosing or monitoring cancer metastasis in a subject, comprising assessing processed LOX or LOXL levels or activity in the blood or in a tumor, whereby a change in processed LOX or LOXL levels or activity in the blood or in the tumor in comparison with a reference sample, indicates the presence of metastatic tumor growth. The change may be an increase or a decrease in processed LOX or LOXL levels or activity. Generally, an increase in processed LOX or LOXL levels or activity in the blood or tumor sample, as compared to a reference sample, indicates the presence of metastatic tumor growth.

As described in more detail below, levels of processed LOX or LOXL can be assessed by various methods including but are not limited to immunohistochemistry by using antibodies that specifically bind to the processed form of LOX or LOXL. Enzymatic activity of active LOX or LOXL can be measured by using various methods including but not limited to chromogenic and fluorometric assays.

VI. Treatment of Fibrosis

Also provided herein are compositions, methods, and kits for preventing and treating various diseases associated with fibrosis, by using an inhibitor of an active form of lysyl oxidase (LOX) or lysyl oxidase-like proteins (LOXL). In one aspect, a method is provided for treating a pathological cardiac condition or disease in a subject, comprising: administering to the subject an effective amount of an inhibitor of LOX or LOXL. For example, the pathological cardiac condition or disease may be hypertension, hypertensive heart disease (HHD), myocardial infarction (MI), atherosclerosis, or restenosis.

In another aspect, a method is provided for preventing a pathological cardiac condition or disease in a subject, comprising: administering to the subject an effective amount of an inhibitor of LOX or LOXL prior to, concurrently, or post an adverse cardiac event. The adverse cardiac event may be myocardial infarction, such as acute myocardial infarction.

The inhibitor of LOX or LOXL may be administered prior to, concurrently, or post the adverse cardiac event. For example, the inhibitor may be administered at least 1 hr, 2 hrs, 3 hrs, 5 hrs, or 10 hrs, or 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12 hours.
11, 12, 13, 14 or more days after myocardial infarction.

[0078] The inhibitor of LOX or LOXL may be delivered to the subject locally to the site of fibrosis caused by the adverse cardiac event.

[0079] In yet another aspect, a device is provided for preventing or treating a pathological cardiac condition or disease in a subject, comprising: a component comprising an inhibitor of LOX or LOXL. The component may be a stent incorporating an inhibitor of LOX or LOXL, which may be a small molecule with a molecular weight below 500 Dalton, such as β-aminoproprionitrile (BAPN). The inhibitor may be coated on the stent.

[0080] Alternatively, the device may comprise a catheter for delivering the inhibitor of LOX or LOXL locally to the site of cardiac fibrosis caused by the adverse cardiac event.

[0081] In still another aspect, a kit is provided comprising: a pharmaceutical composition comprising an inhibitor of LOX or LOXL in a pharmaceutically acceptable excipient; and instructions for how to treat or prevent a pathological cardiac condition or disease using the pharmaceutical composition.

[0082] Also provided are methods, compositions, and kits for treating or preventing a disease associated with fibrosis in a subject, comprising: administering to the subject an effective amount of an inhibitor of LOX or LOXL. The disease associated with fibrosis may be selected from liver fibrosis, kidney fibrosis, lung fibrosis, dermal scarring and keloid formation, and Alzheimer's disease.

[0083] The inhibitor of LOX or LOXL may be an inhibitor of an active LOX or LOXL. The active LOX or LOXL may be a mature form of the LOX or LOXL after proteolytic processing or cleavage. Examples of LOXL include but are not limited to LOXL1, LOXL2, LOXL3, and LOXL4. The inhibitor LOX or LOXL can be an inhibitor of active LOX, LOXL2 or LOXL4.

In some embodiments, the inhibitor LOX or LOXL inhibits both active LOX and active LOXL2.

[0084] The LOX or LOXL inhibitor may be an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.

[0085] In certain embodiments, the LOX or LOXL inhibitor is an antibody specifically binding to a region of LOX or LOXL having an amino acid sequence selected from the group consisting of SEQ ID NOs:1-18, as shown in Tables 1 and 2 below.

[0086] As described in more detail below and in the examples, various inhibitors of LOX or LOXL (such as small molecules or antibodies) may be used.

1. Lysyl Oxidase and Lysyl Oxidase-like Proteins

[0087] As used herein, the term "lysyl oxidase" refers to an enzyme that catalyzes the following reaction: peptidyl-L-lysyl-peptide + O₂ + H₂O → peptidyl-allysyl-peptide + NH₃ + H₂O₂. Other synonyms for lysyl oxidase (EC 1.4.3.13) include protein-lysine 6-oxidase and protein-L-lysine:oxygen 6-oxidoreductase (deaminating). See, e.g., Harris et al., Biochim. Biophys. Acta 341: 332-44 (1974); Rayton et al., J. Biol. Chem. 254:621-26 (1979); Stassen, Biophys. Acta 438:49-60 (1976). A copper-containing quinoprotein with a lysyl adduct of tyrosyl quinone at its active center, lysyl oxidase catalyzes the oxidation of peptidyl lysine to result in the formation of peptidyl alpha-aminoadipic-delta-semialdehyde. Once formed, this semialdehyde can spontaneously condense with neighboring aldehydes or with other lysyl groups to form intra- and interchain cross-links. See, e.g., Rucker et al., Am. J. Clin. Nutr. 67:996S-1002S (1998). An example of lysyl oxidase or lysyl oxidase-like protein include the enzyme having an amino acid sequence substantially identical to a polypeptide expressed or translated from one of the following sequences: EMBL/GenBank accessions: M94054; AAA59525.1 — mRNA; S45875; AAB23549.1—mRNA; S78694; AAB21243.1—mRNA; AF039291; AAKS 1671.1; and LOXL4, encoded by mRNA deposited at GenBank/EMBL AF338441; AAK71934.1.

[0088] Examples of a lysyl oxidase-like enzyme or protein are described in Molnar et al., Biochim. Biophys. Acta 1647: [0088]. Genomic DNA. One embodiment of LOX is human lysyl oxidase (hLOX) preproprotein.

[0089] LOXL having an amino acid sequence selected from the group consisting of SEQ ID NOs:1-18, as shown in Tables 1 and 2 below.
Lysyl oxidase catalyzes oxidative deamination of peptide lysine and hydroxylysine residues in collagen, and peptide lysine residues in elastin, and is essential for the formation of the extracellular matrix. The resulting peptide aldehydes spontaneously condense and undergo oxidation reactions to form the lysine-derived covalent cross-links required for the normal structural integrity of the extracellular matrix. Hydrogen peroxide ($\text{H}_2\text{O}_2$) and ammonium are released in quantities stoichiometric with the peptide aldehyde product. See, e.g., Kagan et al., J. Cell Biochem 88: 660-672 (2003).

The main activity of LOX is the oxidation of specific lysine residues in collagen and elastin outside of the cell, however, it may also act intracellularly, where it may regulate gene expression (Li et al., Proc. Natl. Acad. Sci. USA 94: 12817-12822 (1997); Giampuzzi et al., J. Biol. Chem. 275:36341-36349 (2000)). In addition, LOX enhances chemotaxis of monocytes, fibroblasts and smooth muscle cells (Lazarus et al., Matrix Biol. 14:727-731 (1995); Nelson et al., Proc. Soc. Exp. Biol. Med. 188: 346-352 (1988)). LOX itself is induced by a number of growth factors and steroids such as TGF-$\beta$, TNF-$\alpha$ and interferon (Csiszar, Prog. Nucl. Acid Res. 70:1-32 (2001)). Recent studies have attributed other roles to LOX in diverse biological functions such as developmental regulation, tumor suppression, cell motility, and cellular senescence. The diverse role of LOX, and its recently discovered amino oxidase family, LOX-like (LOXL), may play important roles with their intracellular and extracellular localization.

Five different lysyl oxidases are known to exist in both humans and mice, LOX and four LOX related, or LOX-like proteins (LOXL1, LOXL2, LOXL3, LOXL4), referred to collectively as "LOX/LOXL" for the purposes of this disclosure. The five forms of lysyl oxidases reside on five different chromosomes. These family members show some overlap in structure and function, but appear to have distinct functions as well. For example, targeted LOX deletion by mutagenesis appears to be lethal at parturition in mice (Hornstra et al., J. Biol. Chem. 278:14387-14393 (2003)), whereas LOXL deficiency causes no severe developmental phenotype (Bronson et al., Neurosci. Lett. 390:118-122 (2005)).

LOX has highly conserved protein domains, conserved in several species including human, mouse, rat, chicken, fish and Drosophila. The human LOX family has a highly conserved C-terminal region containing the 205 amino acid LOX catalytic domain. The conserved region contains the copper binding (Cu), conserved cytokine receptor like domain (CR1), and the lysyl-tyrosylquinone cofactor site (LTQ). The predicted extracellular signal sequences are represented by the boxed boxes. Twelve cysteine residues are also similarly conserved, wherein two of them reside within the propeptide region and ten are in the catalytically active processed form of LOX (Csiszar, Prog. Nucl. Acid Res. 70: 1-32 (2001)). The conserved region also includes a fibronectin binding domain.

The propeptide region of LOX contains the signal peptide, and is cleaved, the cleavage site predicted to be between Cys21-Ala22, to generate a signal sequence peptide and a 48kDa amino acid propeptide form of LOX, also referred herein as full-length form. The propeptide is N-glycosylated during passage through the Golgi that is secreted into the extracellular environment where the proenzyme, or propeptide, is cleaved between Gly168-Asp169 by a metalloendopeptidase, a procollagen C-protease, which are products of the Bmp1, Tll1 and Tll2 genes, to produce a processed or mature form of the enzyme. BMP I (bone morphogenetic protein I) is a procollagen C-protease that processes the propeptide to yield a functional 30 kDa enzyme and an 18 kDa propeptide. The sequence coding for the propeptide is moderately (60-70%) conserved, whereas the sequence coding for the C-terminal 30 kDa region of the proenzyme in which the active site is located is highly conserved (approximately 95%). (Kagan and Li, J. Cell. Biochem. 88: 660-672 (2003); Kagan et al., J. Cell Biochem. 59:329-38 (1995)). The N-glycosyl units are also subsequently removed.

Similar potential signal peptides have been predicted at the amino terminus of LOXL, LOXL2, LOXL3, and LOXL4. The predicted signal cleavage sites are between Gly25-Gln26 for LOXL, between Ala25-Gln26, for LOXL2, and between Gly25-Ser26 for LOXL3. The consensus for BMP-1 cleavage in procollagens and pro-LOX is between Ala/Gly-Asp, and often followed by an acidic or charged residue. A potential cleavage site to generate processed LOXL is Gly303-Asp304, however, it is then followed by an atypical Pro. LOXL3 also has a potential cleavage site at Gly447-Asp448, which is followed by an Asp, processing at this site may yield a mature peptide of similar size to mature LOX. A potential cleavage site of BMP-1 was also identified within LOXL4, at residues Ala569-Asp570 (Kim et al., J. Biol. Chem. 278: 52071-52074 (2003)). LOXL2 may also be proteolytically cleaved analogously to the other members of the LOXL family and secreted into media (Akiri et al., Cancer Res. 63:1657-1666 (2003)).

A feature not known to be common amongst LOX and LOXL is the scavenger receptor cysteine rich (SRCR) domains. LOX and LOXL lack SRCR domains, whereas LOXL2, LOXL3, and LOXL4 each have four SRCR domains at the N-terminus. SRCR domains are found in secreted, transmembrane, or extracellular matrix proteins. SRCR domains are also known to mediate ligand binding in a number of secreted and receptor proteins (Hoheneste et al., Nat. Struct. Biol. 6:228-232 (1999); Sasaki et al., EMBO J. 17:1606-1613 (1998)). Another domain unique to LOXL is the presence of a proline rich domain (Molnar et al., Biochimica Biophysica Acta 1647:220-224 (2003)).

Tissue distribution may also differ amongst LOX and the various LOXL. LOX is highly expressed in the heart, placenta, testis, lung, kidney and uterus, but marginally in the brain and liver. LOXL1 is expressed in the placenta, kidney,
muscle, heart, lung, and pancreas, and as with LOX, has much lower expressing in the brain and liver (Kim et al., J. Biol. Chem. 270:7176-7182 (1995)). LOXL2 is highly expressed in the uterus, placenta, and other organs, but similar to LOX and LOXL, lowly expressed in the brain and liver (Jourdan Le-Saux et al., J. Biol. Chem. 274:12939-12944 (1999)). LOX3 is highly expressed in the testis, spleen, and prostate, moderately in placenta, and not in the liver, whereas LOXL4 is highly expressed in the liver (Huang et al., Matrix Biol. 20:153-157 (2001); Maki and Kivirikko, Biochem. J. 355:381-387 (2001); Jourdan Le-Saux et al., Genomics 74:211-218 (2001); Asuncion et al., Matrix Biol. 20:487-491 (2001)).

[0099] The expression, or implication of LOX and the different LOXL proteins, in diseases may also vary. This may be due to a number of reasons, such as the difference in tissue distribution, processing, domains, regulation of activity, as well as other differences between the proteins. For example, LOX and LOXL are implicated in fibrotic diseases as both LOX and LOXL are highly expressed in myo-fibroblasts around fibrotic areas (Kagen, Pathol. Res. Pract. 190:910-919 (1994); Murawaki et al., Hepatology 14:1167-1173 (1991); Siegel et al., Proc. Natl. Acad. Sci. USA 75:2945-2949 (1978); Jourdan Le-Saux et al., Biochem. Biophys. Res. Comm. 199:587-592 (1994); Kim et al., J. Cell Biochem. 72:181-188 (1999)). LOX and the various LOXL are also implicated in a number of cancers. For example, LOXL1 and LOXL4 have been shown to be epigenetically silenced and can inhibit ras/extracellular signal-regulated kinase signaling pathway in human bladder cancer (Wu et al., Cancer Res. 67:4123-4129 (2007)). Others have shown selective upregulation and amplification of the LOXL4 gene in head and neck squamous cell carcinoma (Gorough et al., J. Pathol. 212:74-82 (2007)). LOX and LOXL2 have also been implicated in a number of tumors, such as colon and esophageal cancers (Csiszar, Prog. Nucl. Acid Res. 70:1-32 (2001)). In breast cancer, LOX and the LOXL family members have been linked to the cancer (Kirschmann et al., Cancer Res. 62:448-4483 (2002)).

2. Screening for Modulators of Active LOX/LOXL

[0100] Modulators of active LOX/LOXL can also be selected by using a wide variety of screening assays. The active LOX/LOXL, after secretion and proteolytic cleavage of the preproprotein, can be selected by using a wide variety of screening assays. In one embodiment, methods are provided for selecting a compound that binds to an active LOX/LOXL, comprising incubating a candidate binding compound with a polypeptide of an active LOX or LOXL; and determining if binding has occurred.

[0101] In another embodiment, methods are provided for identifying a modulator, e.g., activators/agonists or inhibitors/antagonists of an active LOX/LOXL, comprising incubating a candidate compound with active LOX/LOXL; and determining if the biological activity of the active LOX/LOXL has been altered.

[0102] In another embodiment, methods are provided for identifying activators or inhibitors of active LOX/LOXL, comprising incubating a candidate compound in a cell culture containing active LOX/LOXL; and detecting the change of biological activity of the cells in the culture, wherein the change of the biological activity of the cells in the culture is indicative for an activator or inhibitors of active LOX/LOXL. The change in biological activity may be a LOX/LOXL specific function, LOX/LOXL enzymatic activity, or levels of LOX/LOXL. In some embodiments, the biological activity is a cellular function, such as migration, EMT/MET, or others and the change is compared to control or reference sample(s). For example, controls may be negative control samples may include a culture with decrease levels of active LOX/LOXL to which the candidate compound is added or a culture with the same amount of active LOX/LOXL but no candidate compound added. In some embodiments, separate cultures containing different amounts of active LOX/LOXL are contacted with a candidate compound. For example, if a change in biological activity is observed, and if the change is greater in the culture having higher amounts of active LOX/LOXL, the compound is identified as an activator of active LOX/LOXL.

[0103] In another example, expressing significant amount of LOX and/or LOXL can be used as a source for active LOX/LOXL for the screening assays described herein, whereas whole cell lysate would contain not only active LOX and/or LOXL but also inactive LOX and/or LOXL.

[0104] The plurality or combination of compounds may be chemically synthesized or microbiologically produced and/or comprised in, for example, samples, e.g., cell extracts from, e.g., plants, animals or microorganisms. Furthermore, the compound(s) may be known in the art but hitherto not known to be capable of suppressing or activating active LOX/LOXL. The reaction mixture may be a cell free extract or may comprise a cell or tissue culture: Suitable set up for the method of the disclosure are known to the person skilled in the art and are, for example, generally described in Alberts et al., Molecular Biology of the Cell, third edition (1994) and in the appended examples. A plurality of compounds may be, e.g., added to the reaction mixture, culture medium, injected into a cell or otherwise applied to a transgenic animal. The cell or tissue that may be employed in the method of the disclosure is a host cell, mammalian cell or non-human transgenic animal of the disclosure.

[0105] If a sample containing a compound or a plurality of compounds is identified in the method of the disclosure, then it is either possible to isolate the compound from the original sample identified as containing the compound capable of suppressing or activating active LOX/LOXL, or one can further subdivide the original sample, for example, if it consists...
of a plurality of different compounds, so as to reduce the number of different substances per sample and repeat the method with the subdivisions of the original sample. Depending on the complexity of the samples, the steps described above can be performed several times, for example, until the sample identified according to the method of the disclosure only comprises a limited number of or only one substance(s). In some embodiments the sample comprises substances of similar chemical and/or physical properties, and in some embodiments, the substances are identical.

[0106] Several methods are known to the person skilled in the art for producing and screening large libraries to identify compounds having specific affinity for a target, such as active LOX/LOXL. These methods include the phage-display method in which randomized peptides are displayed from phage and screened by affinity chromatography to an immobilized receptor; see, e.g., WO 91/17271, WO 92/01047, U.S. Patent No. 5,223,409.

[0107] In another approach, combinatorial libraries of polymers immobilized on a chip are synthesized using photolithography; see, e.g., U.S. Patent No. 5,143,854, WO 90/15070 and WO 92/10092. The immobilized polymers are contacted with a labeled receptor and scanned for label to identify polymers binding to the receptor. The synthesis and screening of peptide libraries on continuous cellulose membrane supports that can be used for identifying binding ligands of the polypeptide of the disclosure and thus possible inhibitors and activators is described, for example, in Kramer, Methods Mol. Biol. 87 (1998), 25-39. This method can also be used, for example, for determining the binding sites and the recognition motifs in the active LOX/LOXL. In like manner, the substrate specificity of the DnaK chaperon was determined and the contact sites between human interleukin-6 and its receptor; see Rudiger, EMBO J. 16 (1997), 1501-1507 and Weiergraber, FEBS Lett. 379 (1996), 122-126, respectively.

[0108] Furthermore, the above-mentioned methods can be used for the construction of binding epitopes derived from the active LOX/LOXL. A similar approach was successfully described for peptide antigens of the anti-p24 (HIV-1) monoclonal antibody; see Kramer, Cell 91 (1997), 799-809. A general route to fingerprint analyses of peptide-antibody interactions using the clustered amino acid peptide library was described in Kramer, Mol. Immunol. 32 (1995), 459-465. In addition, antagonists of the active LOX/LOXL can be derived and identified from monoclonal antibodies that specifically react with the polypeptide of the disclosure in accordance with the methods as described in Doring, Mol. Immunol. 31 (1994), 1059-1067.

[0109] More recently, WO 98/25146 described further methods for screening libraries of complexes for compounds having a desired property, e.g., the capacity to agonize, bind to, or antagonize a polypeptide or its cellular receptor. The complexes in such libraries comprise a compound under test, a tag recording at least one step in synthesis of the compound, and a tether susceptible to modification by a reporter molecule. Modification of the tether is used to signify that a complex contains a compound having a desired property. The tag can be decoded to reveal at least one step in the synthesis of such a compound. Other methods for identifying compounds which interact with the polypeptides according to the disclosure or nucleic acid molecules encoding such molecules are, for example, the in vitro screening with the phage display system as well as filter binding assays or "real time" measuring of interaction using, for example, the BIACore apparatus (Pharmacia).

[0110] All these methods can be used in accordance with the present disclosure to identify activators/agonists and inhibitors/antagonists of the active LOX/LOXL or related polypeptide.

[0111] Various sources for the basic structure of such an activator or inhibitor can be employed and comprise, for example, mimetic analogs of the polypeptides of the disclosure. Mimetic analogs of the polypeptide of the disclosure or biologically active fragments thereof can be generated by, for example, substituting the amino acids that are expected to be essential for the biological activity with, e.g., stereoisomers, i.e. D-amino acids; see e.g., Tsukida, J. Med. Chem. 40 (1997), 3534-3541. Furthermore, in case fragments are used for the design of biologically active analogs pro-mimetic components can be incorporated into a peptide to reestablish at least some of the conformational properties that may have been lost upon removal of part of the original polypeptide; see, e.g., Nachman, Regul. Pept. 57 (1995), 359-370. Furthermore, the active LOX/LOXL can be used to identify synthetic chemical peptide mimetics that bind to or can function as a ligand, substrate, binding partner or the receptor of the polypeptide of the disclosure as effectively as does the natural polypeptide; see, e.g., Engleman, J. Clin. Invest. 99 (1997), 2284-2292. For example, folding simulations and computer redesign of structural motifs of the active LOX/LOXL can be performed using appropriate computer programs (Olszewski, Proteins 25 (1996), 286-299; Hoffman, Comput. Appl. Biosci. 11 (1995), 675-679). Computer modeling of protein folding can be used for the conformational and energetic analysis of detailed peptide and protein models (Monge, J. Mol. Biol. 247 (1995), 995-1012; Renouf, Adv. Exp. Med. Biol. 376 (1995), 37-45). The appropriate programs can be used for the identification of interactive sites of the Lysyl Oxidase polypeptide and its interacting proteins by computer assisted searches for complementary peptide sequences (Fassina, Immunomethods 5 (1994), 114-120). Further appropriate computer systems for the design of protein and peptides are described in the prior art, for example in Berry, Biochem. Soc. Trans. 22 (1994), 1033-1036; Wodak, Ann. N. Y. Acad. Sci. 501 (1987), 1-13; Pabo, Biochemistry 25 (1986), 5987-5991. The results obtained from the above-described computer analysis can be used for, e.g., the preparation of peptide mimetics of the protein of the disclosure or fragments thereof. Such pseudopeptide analogues of the natural amino acid sequence of the protein may very efficiently mimic the parent protein (Benkirane, J. Biol. Chem. 271 (1996), 33218-33224). For example, incorporation of easily available achiral α-amino acid residues into a protein...
of the disclosure or a fragment thereof results in the substitution of amide bonds by polymethylene units of an aliphatic chain, thereby providing a convenient strategy for constructing a peptide mimic (Banerjee, Biopolymers 39 (1996), 769-777). Superactive peptidomimetic analogues of small peptide hormones in other systems are described in the prior art (Zhang, Biochem. Biophys. Res. Commun. 224 (1996), 327-331). Appropriate peptide mimetics of a modulator of an active LOX/LOXL can also be identified by the synthesis of peptide mimetic combinatorial libraries through successive amide alkylation and testing the resulting compounds, e.g., for their binding and immunological properties. Methods for the generation and use of peptidomimetic combinatorial libraries are described in the prior art, for example in Ostresh, Methods in Enzymology 267 (1996), 220-234 and Dorner, Bioorg. Med. Chem. 4 (1996), 709-715. Furthermore, a threedimensional and/or crystallographic structure of the polypeptide of the disclosure can be used for the design of peptide mimetic inhibitors of the biological activity of the polypeptide of the disclosure (Rose, Biochemistry 35 (1996), 12933-12944; Rutenber, Bioorg. Med. Chem. 4 (1996), 1545-1558).

[0113] It is also well known to the person skilled in the art, that it is possible to design, synthesize and evaluate mimetics of small organic compounds that, for example, can act as a substrate or ligand to the active LOX/LOXL or the related polypeptide. For example, it has been described that D-glucose mimetics of hapalosin exhibited similar efficiency as hapalosin in antagonizing multidrug resistance assistance-associated protein in cytotoxicity; see Dinh, J. Med. Chem. 41 (1998), 981-987.

[0114] The inhibitors disclosed herein, such as antibodies, can bind to LOX/LOXL and can be competitive inhibitors, uncompetitive inhibitors or non-competitive inhibitors. With respect to competitive inhibition, an inhibitor usually bears structural similarity to substrate. Inhibition will be noticeable at low substrate concentrations, but can be overcome at high substrate concentrations. With respect to non-competitive inhibition, an inhibitor binds at a site that becomes available after substrate is bound at the active site. Inhibition will be most noticeable at high substrate concentration. With respect to non-competitive inhibition, an inhibitor binds at a site away from substrate binding site and relative inhibition will generally be the same at all substrate concentrations. In one embodiment, an antibody or antigen binding fragment thereof, described herein specifically binds both full-length and processed LOX or LOXL2. In one aspect, both full-length and processed LOX or LOXL2 are active forms of the enzyme.

3. Antibodies Against LOX/LOXL

[0115] As used herein, the term "antibody" means an isolated or recombinant binding agent that comprises the necessary variable region sequences to specifically bind an antigenic epitope. Therefore, an antibody is any form of antibody or fragment thereof that exhibits the desired biological activity, e.g., binding the specific target antigen. Thus, it is used in the broadest sense and specifically covers monoclonal antibodies (including full-length monoclonal antibodies), polyclonal antibodies, human antibodies, humanized antibodies, chimeric antibodies, nanobodies, diabodies, multispecific antibodies (e.g., bispecific antibodies), and antibody fragments including but not limited to scFv, Fab, and Fab\(_2\), so long as they exhibit the desired biological activity. The term "human antibody" therefore refers to antibodies containing sequences of human origin, except for possible non-human CDR regions, and does not imply that the full structure of an Ig molecule be present, only that the antibody has minimal immunogenic effect in a human.

[0116] "Antibody fragments" comprise a portion of an intact antibody, for example, the antigen binding or variable region of the intact antibody. Examples of antibody fragments include Fab, Fab\(_1\), F(ab\(_2\))\(_2\), and Fv fragments; diabodies; linear antibodies (Zapata et al., Protein Eng. 8(10): 1057-1062 (1995)); single-chain antibody molecules; and multispecific antibodies formed from antibody fragments. Papain digestion of antibodies produces two identical antigen-binding fragments, called "Fab" fragments, each with a single antigen-binding site, and a residual "Fc" fragment, a designation reflecting the ability to crystallize readily. Pepsin treatment yields an F(ab\(_2\))\(_2\) fragment that has two antigen combining sites and is still capable of cross-linking antigen.

[0117] "Fv" is the minimum antibody fragment which contains a complete antigen-recognition and -binding site. This region consists of a dimer of one heavy- and one light-chain variable domain in tight, non-covalent association. It is in this configuration that the three CDRs of each variable domain interact to define an antigen-binding site on the surface of the V\(_{\text{H}}\)-V\(_{\text{L}}\) dimer. Collectively, the six CDRs confer antigen-binding specificity to the antibody. However, even a single variable domain (or half of an Fv comprising only three CDRs specific for an antigen) has the ability to recognize and bind antigen, although at a lower affinity than the entire binding site.

[0118] The "Fab" fragment also contains the constant domain of the light chain and the first constant domain (CH\(_1\)) of the heavy chain. Fab fragments differ from Fab' fragments by the addition of a few residues at the carboxy terminus of the heavy chain CH\(_1\) domain including one or more cysteines from the antibody hinge region. Fab'-SH is the designation herein for Fab' in which the cysteine residue(s) of the constant domains bear a free thiol group. F(ab')\(_2\) antibody fragments...
The "light chains" of antibodies (immunoglobulins) from any vertebrate species can be assigned to one of two clearly distinct types, called kappa and lambda, based on the amino acid sequences of their constant domains. Depending on the amino acid sequence of the constant domain of their heavy chains, immunoglobulins can be assigned to different classes. There are five major classes of immunoglobulins: IgA, IgD, IgE, IgG, and IgM, and several of these may be further divided into subclasses (isotypes), e.g., IgG1, IgG2, IgG3, IgG4, IgA, and IgA2.

"Single-chain Fv" or "sFv" antibody fragments comprise the VH and VL domains of antibody, wherein these domains are present in a single polypeptide chain. In some embodiments, the Fv polypeptide further comprises a polypeptide linker between the VH and VL domains, which enables the sFv to form the desired structure for antigen binding. For a review of sFv, see Pluckthun in The Pharmacology of Monoclonal Antibodies, vol. 113, Rosenberg and Moore eds., Springer-Verlag, New York, pp. 269-315 (1994).

The term "diabodies" refers to small antibody fragments with two antigen-binding sites, which fragments comprise a heavy-chain variable domain (VH) connected to a light-chain variable domain (VL) in the same polypeptide chain (VH–VL). By using a linker that is too short to allow pairing between the two domains on the same chain, the domains are forced to pair with the complementary domains of another chain and create two antigen-binding sites. Diabodies are described more fully in, for example, EP 404,097; WO 93/11161; and Hollinger et al., Proc. Natl. Acad. Sci. USA, 90: 6444-6448 (1993).

An "isolated" antibody is one that has been identified and separated and/or recovered from a component of its natural environment. Contaminant components of its natural environment are materials that would interfere with diagnostic or therapeutic uses for the antibody, and may include enzymes, hormones, and other proteinaceous or nonproteinaceous solutes. In some embodiments, the antibody will be purified (1) to greater than 95% by weight of antibody as determined by the Lowry method, for example, more than 99% by weight, (2) to a degree sufficient to obtain at least 15 residues of N-terminal or internal amino acid sequence by use of a spinning cup sequenator, or (3) to homogeneity by SDS-PAGE under reducing or nonreducing conditions using Coomassie blue or silver stain. Isolated antibody includes the antibody in situ within recombinant cells since at least one component of the antibody's natural environment will not be present. Ordinarily, however, isolated antibody will be prepared by at least one purification step.

In some embodiments the anti-LOX/LOXL antibody is a humanized antibody or a human antibody. Humanized forms of non-human (e.g., murine) antibodies are chimeric immunoglobulins, immunoglobulin chains or fragments thereof (such as Fv, Fab, Fab', F(ab')2 or other antigen-binding subsequences of antibodies) which contain minimal sequence derived from non-human immunoglobulin. Humanized antibodies include human immunoglobulins (recipient antibody) in which residues from a complementary determining region (CDR) of the recipient are replaced by residues from a CDR of a non-human species (donor antibody) such as mouse, rat or rabbit having the desired specificity, affinity and capacity. In some instances, Fv framework residues of the human immunoglobulin are replaced by corresponding non-human residues. Humanized antibodies may also comprise residues that are found neither in the recipient antibody nor in the imported CDR or framework sequences. In general, the humanized antibody will comprise substantially all of at least one, and typically two, variable domains, in which all or substantially all of the CDR regions correspond to those of a non-human immunoglobulin and all or substantially all of the FR regions are those of a human immunoglobulin consensus sequence.

Methods for humanizing non-human antibodies are well known in the art. Generally, a humanized antibody has one or more amino acid residues introduced into it from a source that is non-human. These non-human amino acid residues are often referred to as "import" or "donor" residues, which are typically taken from an "import" or "donor" variable domain. Humanization can be essentially performed following the method of Winter and co-workers (Jones et al., Nature, 321:522 525 (1986); Riechmann et al., Nature, 332:323 327 (1988)); Verhoeyen et al. Science, 239:1534 1536 (1988)), by substituting rodent CDRs or CDR sequences for the corresponding sequences of a human antibody. Accordingly, such "humanized" antibodies include chimeric antibodies (U.S. Patent No. 4,816,567), wherein substantially less than an intact human variable domain has been substituted by the corresponding sequence from a non-human species. In practice, humanized antibodies are typically human antibodies in which some CDR residues and possibly some FR residues are substituted by residues from analogous sites in rodent antibodies.

Human antibodies can also be produced using various techniques known in the art, including phage display libraries (Hoogenboom and Winter, J. Mol. Biol., 227:381 (1991); Marks et al., J. Mol. Biol., 222:581 (1991)). The techniques of Cole et al. and Boener et al. are also available for the preparation of human monoclonal antibodies (Cole et al., Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, p. 77 (1985) and Boerner et al., J. Immunol., 147(1): 86-95 (1991)). Similarly, human antibodies can be made by introducing human immunoglobulin loci into transgenic animals, e.g., mice in which the endogenous immunoglobulin genes have been partially or completely inactivated. Upon
The LOX/LOXL antibodies of the present disclosure can be competitive inhibitors, uncompetitive inhibitors, or non-competitive inhibitors. The anti-LOX/LOXL antibody may also be a bispecific antibody. Bispecific antibodies are monoclonal, any may be human or humanized antibodies that have binding specificities for at least two different antigens. In the present case, one of the binding specificities is for LOX, the other one is for any other antigen, for example, for a cell-surface protein or receptor or receptor subunit. In additional embodiments, one of the binding specificities is for LOX, and the other is for a LOXL protein; e.g., LOXL2 or LOXL4.

 Optionally, the antibody of the present disclosure not only binds to LOX or LOXL but also reduces or inhibits LOX or LOXL-like or lysyl oxidase-related proteins (e.g., LOXL1, LOXL2, LOXL3, and LOXL4; see Molnar et al. (2003) Biochim Biophys. Acta. 1647:220-224; Csiszar, Prog. Nucl. Acid Res. 70:1-32 (2001); and WO 0 1/83702 published on Nov. 8, 2001).

 Optionally, the antibody of the present disclosure specifically and selectively binds to the mature or processed form of LOX, with a greater binding affinity, for example, at least 10 times, at least 100 times, or even at least 1000 times greater, than the binding affinity to the preproprotein of human LOX, the mature or processed human LOX, or other lysyl oxidase-like or lysyl oxidase-related proteins (e.g., LOXL1, LOXL2, LOXL3, and LOXL4; see Molnar et al. (2003) Biochim Biophys. Acta. 1647:220-224; Csiszar, Prog. Nucl. Acid Res. 70:1-32 (2001); and WO 0 1/83702 published on Nov. 8, 2001).

 Optionally, the antibody of the present disclosure specifically and selectively binds to the mature or processed form of LOX, with a greater binding affinity, for example, at least 10 times, at least 100 times, or even at least 1000 times greater, than the binding affinity to the preproprotein of human LOX, the mature or processed human LOX, or other lysyl oxidase-like or lysyl oxidase-related proteins (e.g., LOXL1, LOXL2, LOXL3, and LOXL4; see Molnar et al. (2003) Biochim Biophys. Acta. 1647:220-224).

 Optionally, the antibody of the present disclosure binds to one or more proteolytic cleavage sites of LOX or LOXL, such as the cleavage site for processing a mature form of LOX/LOXL, thereby effectively blocking processing of the LOX or LOXL to reduce the level of active LOX or LOXL.

 Optionally, the antibody of the present disclosure specifically and selectively binds to the full-length form of LOX, with a greater binding affinity, for example, at least 10 times, at least 100 times, or even at least 1000 times greater, than the binding affinity to any other polypeptide or polypeptide epitope. In some embodiments, the antibody of the present disclosure specifically binds to a human LOX/LOXL (such as hLOX and hLOXL1-4) with dissociation constant Kd equal to or lower than 100 nM, optionally lower than 10 nM, optionally lower than 1 nM, optionally lower than 0.5 nM, optionally lower than 0.1 nM, optionally lower than 0.01 nM, or optionally lower than 0.005 nM, in the form of monoclonal antibody, scFv, Fab, or other form of antibody measured at a temperature of about 4°C, 25°C, 37°C or 42°C.

 Optionally, the antibody of the present disclosure binds to an epitope in a region of hLOX selected from SEQ ID NOs: 1-18.

 Optionally, the antibody of the present disclosure binds to both human LOX and human LOXL2, with a greater binding affinity, for example, 10 times, at least 100 times, or even at least 1000 times greater, than the binding affinity to other lysyl oxidase-like or lysyl oxidase-related proteins (e.g., LOXL1, LOXL3, and LOXL4; see Molnar et al. (2003) Biochim Biophys. Acta. 1647:220-224).

 Optionally, the antibody of the present disclosure not only binds to LOX or LOXL but also reduces or inhibits uptake or internalization of LOX or LOXL (e.g., via integrin beta 1 or other cellular receptors or proteins. It is believed that such an antibody could reduce EMT and thus is useful for the applications disclosed herein.

 Optionally, the antibody of the present disclosure not only binds to LOX or LOXL but also reduces or inhibits the lysyl oxidase enzymatic activity of LOX or LOXL. It is believed that such an antibody could reduce EMT and thus is useful for the applications disclosed herein.

 Some LOX/LOXL antibodies that inhibit LOX/LOXL binding to ECM proteins, cellular receptors, and integrins, are selected as candidates for further development.

 LOX/LOXL enzymes act via a ping-pong mechanism which can be described by Michaelis-Menten kinetics (FIGURE 41). The LOX/LOXL antibodies of the present disclosure can be competitive inhibitors, uncompetitive inhibitors.
or non-competitive inhibitors of LOX/LOXL. The mechanism of action antibodies that act as competitive inhibitors, un-
competitive inhibitors and non-competitive inhibitors is illustrated in FIGURE 42. With respect to competitive inhibition,
an inhibitor usually bears structural similarity to substrate. Inhibition will be noticeable at low substrate concentrations,
but can be overcome at high substrate concentrations. With respect to uncompetitive inhibition, an inhibitor binds at site
that becomes available after substrate is bound at the active site. Inhibition will be most noticeable at high substrate
concentration. With respect to non-competitive inhibition, an inhibitor binds at site away from substrate binding site.
Relative inhibition will generally be the same at all substrate concentrations. Thus, inhibitors can be LOX/LOXL antibodies,
such as LOXL2, which are competitive inhibitors, uncompetitive inhibitors or non-competitive inhibitors (FIGURE 43).

4. Polynucleotides Targeting LOX/LOXL.

[0141] Inhibitors of LOX or LOXL levels or activity can be effected using an antisense polynucleotide capable of
specifically hybridizing with an mRNA transcript encoding LOX or LOXL.

[0142] Optionally, the polynucleotide inhibitors of the present disclosure can reduce or inhibits uptake or internalization
of LOX or LOXL. It is believed that such a polynucleotide inhibitor could reduce EMT and thus is useful for the applications
disclosed herein.

[0143] Optionally, the polynucleotide inhibitors of the present disclosure can reduce or inhibit the lysyl oxidase enzym-
atic activity of LOX or LOXL. It is believed that such a polynucleotide inhibitor could reduce EMT and thus is useful for
the applications disclosed herein.

[0144] Design of antisense molecules which can be used to efficiently downregulate LOX or LOXL2 is typically effected
while considering two aspects factors used in the antisense approach. The first aspect is delivery of the oligonucleotide
into the cytoplasm of the appropriate cells, while the second aspect is design of an oligonucleotide which specifically
binds the designated mRNA within cells in a way which inhibits translation thereof.

[0145] Several considerations are typically taken into account when designing antisense oligonucleotides. For efficient
in vivo inhibition of gene expression using antisense oligonucleotides or analogs, the oligonucleotides or analogs typically
fulfill the following requirements (i) sufficient specificity in binding to the target sequence; (ii) solubility in water; (iii) stability
against intra- and extracellular nucleases; (iv) capability of penetration through the cell membrane; and (v) when used
to treat an organism, low toxicity. Algorithms for identifying those sequences with the highest predicted binding affinity
for their target mRNA based on a thermodynamic cycle that accounts for the energy of structural alterations in both the
target mRNA and the oligonucleotide are available, for example, as described in Walton et al. Biotechnol Bioeng 65:1-9
(1999).

[0146] Such algorithms have been successfully used to implement an antisense approach in cells. For example, the
algorithm developed by Walton et al. enabled scientists to successfully design antisense oligonucleotides for rabbit β-
globin (RBG) and mouse tumor necrosis factor-α (TNF α) transcripts. The same research group has also reported that
the antisense activity of rationally selected oligonucleotides against three model target mRNAs (human lactate dehy-
donerase A and B and rat gp130) in cell culture as evaluated by a kinetic PCR technique proved effective in almost all
cases, including tests against three different targets in two cell types with phosphodiester and phosphorothioate oligo-
nucleotide chemistries.

[0147] In addition, several approaches for designing and predicting efficiency of specific oligonucleotides using an in
vitro system are also published (Matveeva et al., Nature Biotechnology 16: 1374-1375 (1998)).

[0148] An antisense molecule which can be used with the present disclosure includes a polynucleotide or a polynu-
cleotide analog of at least 10 bases, for example, between 10 and 15, between 15 and 20 bases, at least 18, at least 19, at least 20,
at least 22, at least 25, at least 30, or even at least 40 bases which is hybridizable

[0149] The antisense oligonucleotides used by the present disclosure can be expressed from a nucleic acid construct
administered into the tissue, in which case inducible promoters can be used such that antisense expression can be
switched on and off, or alternatively such oligonucleotides can be chemically synthesized and administered directly into
the tissue, as part of, for example, a pharmaceutical composition.

[0150] The ability of chemically synthesizing oligonucleotides and analogs thereof having a selected predetermined
sequence offers means for downmodulating gene expression. Four types of gene expression modulation strategies may
be considered.

[0151] At the transcription level, antisense or sense oligonucleotides or analogs that bind to the genomic DNA by
strand displacement or the formation of a triple helix, may prevent transcription. At the transcript level, antisense oligo-
nucleotides or analogs that bind target mRNA molecules lead to the enzymatic cleavage of the hybrid by intracellular
RNase H. In this case, by hybridizing to the targeted mRNA, the oligonucleotides or oligonucleotide analogs provide a
duplex hybrid recognized and destroyed by the RNase H enzyme. Alternatively, such hybrid formation may lead to interference with correct splicing. As a result, in both cases, the number of the target mRNA intact transcripts ready for translation is reduced or eliminated.

At the translation level, antisense oligonucleotides or analogs that bind target mRNA molecules prevent, by steric hindrance, binding of essential translation factors (ribosomes), to the target mRNA, a phenomenon known in the art as hybridization arrest, disabling the translation of such mRNAs.

Unmodified oligonucleotides are typically impractical for use as antisense sequences since they have short in vivo half-lives, during which they are degraded rapidly by nucleases. Furthermore, they are often difficult to prepare in more than milligram quantities. In addition, such oligonucleotides are usually poor cell membrane penetrants. Thus, oligonucleotide analogs are usually devised in a suitable manner.

For example, problems arising in connection with double-stranded DNA (dsDNA) recognition through triple helix formation have been diminished by a clever "switch back" chemical linking, whereby a sequence of polypurine on one strand is recognized, and by "switching back," a homopurine sequence on the other strand can be recognized. Also, good helix formation has been obtained by using artificial bases, thereby improving binding conditions with regard to ionic strength and pH.

RNA oligonucleotides may also be used for antisense inhibition as they form a stable RNA-RNA duplex with the target, suggesting efficient inhibition. However, due to their low stability, RNA oligonucleotides are typically expressed inside the cells using vectors designed for this purpose. This approach may be used when attempting to target an mRNA that encodes an abundant and long-lived protein.

Antisense therapeutics can be used to treat many life-threatening diseases with a number of advantages over traditional drugs. Traditional drugs typically intervene after a disease-causing protein is formed. Antisense therapeutics, however, can block mRNA transcription/translation and intervene before a protein is formed, and since antisense therapeutics target only one specific mRNA, they can be more effective with fewer side effects than current protein-inhibiting therapy.

Several clinical trials have demonstrated safety, feasibility and activity of antisense oligonucleotides. For example, antisense oligonucleotides suitable for the treatment of cancer have been successfully used (Holmund et al., Curr. Opin. Mol. Ther. 1:372-385 (1999)), while treatment of hematological malignancies via antisense oligonucleotides targeting c-myb gene, p53 and Bcl-2 had entered clinical trials and had been shown to be tolerated by patients (Gerwitz, Curr. Opin. Mol. Ther. 1: 297-306 (1999)).

More recently, antisense-mediated suppression of human heparanase gene expression has been reported to inhibit pleural dissemination of human cancer cells in a mouse model (Uno et al., Cancer Res 61: 7855-60 (2001)).

The first antisense drug was recently approved by the FDA. The drug, Fomivirsen, was developed by Isis, and is indicated for local treatment of cytomegalovirus in patients with AIDS who are intolerant of or have a contraindication to other treatments for CMV retinitis or who were insufficiently responsive to previous treatments for CMV retinitis (Pharmacotherapy News Network).

Thus, the current consensus is that recent developments in the field of antisense technology which, as described above, have led to the generation of highly accurate antisense design algorithms and a wide variety of oligonucleotide delivery systems, enable an ordinarily skilled artisan to design and implement antisense approaches suitable for down-regulating expression of known sequences without having to resort to undue trial and error experimentation.

Another mechanism for inhibiting LOX or LOXL is RNA interference (RNAi), an approach which utilizes small interfering dsRNA (siRNA) or small hairpin RNA, shRNA molecules that are homologous to the target mRNA and lead to its degradation (Carthew, Curr. Opin. Cell. Biol. 13: 244-248 (2001)). For example, infection of diverse types of cancer cells with expression of a LOXL2 specific shRNA is effective in altering both their morphology and invasiveness.

RNA interference is typically a two-step process. In the first step, which is termed as the initiation step, input dsRNA is digested into 21-23 nucleotide (nt) small interfering RNAs (siRNA), probably by the action of Dicer, a member of the RNase III family of dsRNA-specific ribonucleases, which processes (cleaves) dsRNA (introduced directly or via a transgene or a virus) in an ATP-dependent manner. Successive cleavage events degrade the RNA to 19-21 bp duplexes (siRNA), each with 2-nucleotide 3’ overhangs (Hutvagner and Zamore, Curr. Opin. Genet. Dev. 12: 225-232 (2002); Bernstein, Nature 409:363-366 (2001)).

In the effector step, the siRNA duplexes bind to a nuclease complex to form the RNA-induced silencing complex (RISC). An ATP-dependent unwinding of the siRNA duplex is required for activation of the RISC. The active RISC then targets the homologous transcript by base pairing interactions and typically cleaves the mRNA into approximately 12 nucleotide fragments from the 3’ terminus of the siRNA (Hutvagner and Zamore, Curr. Opin. Genet. Dev. 12: 225-232 (2002); Hammond et al., Nat. Rev. Gen. 2:110-119 (2001); Sharp, Genes. Dev. 15:485-490 (2001)). Although the mechanism of cleavage is still to be elucidated, research indicates that each RISC contains a single siRNA and an RNase (Hutvagner and Zamore, Curr. Opin. Genet. Dev. 12: 225-232 (2002)).

Because of the remarkable potency of RNAi, an amplification step within the RNAi pathway has been suggested. Amplification could occur by copying of the input dsRNAs which would generate more siRNAs, or by replication of the

**[0165]** Synthesis of RNAi molecules suitable for use with the present disclosure can be effected as follows. First, the LOX or LOXL mRNA sequence is scanned downstream of the AUG start codon for AA dinucleotide sequences. Occurrence of each AA and the 3' adjacent 19 nucleotides is recorded as potential siRNA target sites. The siRNA target sites are selected from the open reading frame, as untranslated regions (UTRs) are richer in regulatory protein binding sites. UTR-binding proteins and/or translation initiation complexes may interfere with binding of the siRNA endonuclease complex (Tuschl, Chem. Biochem. 2: 239-245 (2001)). It will be appreciated though, that siRNAs directed at untranslated regions may also be effective, as demonstrated for GAPDH wherein siRNA directed at the 5' UTR mediated about 90% decrease in cellular GAPDH mRNA and completely abolished protein level (www.ambion.com/techlib/tn/91912.html). Second, potential target sites are compared to an appropriate genomic database (e.g., human, mouse, rat etc.) using any sequence alignment software, such as the BLAST software available from the NCBI server (www.ncbi.nlm.nih.gov/BLAST/). Putative target sites which exhibit significant homology to other coding sequences are filtered out.

**[0166]** Qualifying target sequences are selected as template for siRNA synthesis. Selected sequences can include those with low G/C content as these have been shown to be more effective in mediating gene silencing as compared to those with G/C content higher than 55%. Several target sites can be selected along the length of the target gene for evaluation. For better evaluation of the selected siRNAs, a negative control is used in conjunction. Negative control siRNA can include the same nucleotide composition as the siRNAs but lack significant homology to the genome. Thus, a scrambled nucleotide sequence of the siRNA may be used, provided it does not display any significant homology to any other gene.

**[0167]** The siRNA molecules of the present disclosure can be transcribed from expression vectors which can facilitate stable expression of the siRNA transcripts once introduced into a host cell. These vectors are engineered to express shRNAs, which are processed in vivo into siRNA molecules capable of carrying out gene-specific silencing (Brummelkamp et al., Science 296:550-553 (2002); Paddison et al., Genes Dev. 16: 948-958 (2002); Pa ul et al., Nature Biotech. 20: 505-508 (2002); Yu et al., Proc. Natl. Acad. Sci. USA 99: 6047-6052(2002)).

**[0168]** ShRNAs are single-stranded polynucleotides with a hairpin loop structure. The single-stranded polynucleotide has a loop segment linking the 3' end of one strand in the double-stranded region and the 5' end of the other strand in the double-stranded region. The double-stranded region is formed from a first sequence that is hybridizable to a target sequence, such as a polynucleotide encoding LOX or LOXL, or a LOX or LOXL mRNA, and a second sequence that is complementary to the first sequence, thus the first and second sequence form a double stranded region to which the linking sequence connects the ends of to form the hairpin loop structure. The first sequence can be hybridizable to any portion of a polynucleotide encoding LOX/LOXL. The double-stranded stem domain of the shRNA comprises a restriction endonuclease site.

**[0169]** The stem-loop structure of shRNAs can have optional nucleotide overhands, such as 2-bp overhands, for example, 3' UU-overhangs. While there may be variation, stems typically range from approximately 15 to 49, approximately 15 to 35, approximately 19 to 35, approximately 21 to 31 bp, or approximately 21 to 29 bp, and the loops can range from approximately 4 to 30 bp, for example, about 4 to 23 bp.

**[0170]** For expression of shRNAs within cells, plasmid vectors containing either the polymerase III H1-RNA or U6 promoter, a cloning site for the stem-looped RNA insert, and a 4 5-thymidine transcription termination signal can be employed. The Polymerase III promoters generally have well-defined initiation and stop sites and their transcripts lack poly(A) tails. The termination signal for these promoters is defined by the polythymidine tract, and the transcript is typically cleaved after the second uridine. Cleavage at this position generates a 3' UU overhang in the expressed shRNA, which is similar to the 3' overhangs of synthetic siRNAs. Additional methods for expressing the shRNA in mammalian cells are described in the references cited above.

**[0171]** An example of a suitable expression vector is the pSUPER™, which includes the polymerase-III H1-RNA gene promoter with a well defined start of transcription and a termination signal consisting of five thymidines in a row (T5) (Brummelkamp et al., Science 296:550-553 (2002)). The cleavage of the transcript at the termination site is at a site following the second uridine, thus yielding a transcript which resembles the ends of synthetic siRNAs, which also contain nucleotide overhangs. siRNA is cloned such that it includes the sequence of interest, i.e., LOX or LOXL separated by a short spacer from the reverse complement of the same sequence. The resulting transcript folds back on itself to form a stem-loop structure, which mediates LOX or LOXL RNAi.

**[0172]** Another suitable siRNA expression vector encodes the sense and antisense siRNA under the regulation of separate polIII promoters (Miyagishi and Taira, Nature Biotech. 20:497-500 (2002)). The siRNA, generated by this vector also includes a five thymidine (T5) termination signal.

**[0173]** Since approaches for introducing synthetic siRNA into cells by lipofection can result in low transfection efficiencies in some cell types and/or short-term persistence of silencing effects, vector mediated methods have been developed.
5. Anti-neoplastic or Anti-fibrotic Agents

According to the present disclosure, an inhibitor of LOX or LOXL can be combined with a chemotherapeutic agent to sensitize the tumor cells (e.g., transition from the EMT state to the MET state) to the chemotherapeutic agent, thus not only preventing or inhibiting tumor invasion and metastasis but also inhibiting primary tumor growth.

As used herein the term "chemotherapeutic agent" or "chemotherapeutic" (or "chemotherapy", in the case of treatment with a chemotherapeutic agent) is meant to encompass any non-proteinaceous (i.e., non-peptidic) chemical compound useful in the treatment of cancer. Examples of chemotherapeutic agents include alkylating agents such as thiota and cyclophosphamide (CYTOXAN™); alkyl sulfonates such as busulfan, imprison and piposulfan; aziridines such as benzodopa, carboquone, meturedopa, and uredopa; ethylamines and methylamines including buteramine, triethylenemamine, triethylene phosphoramide, triethylenetriphosphoramide and trimethylolomelamine; actogenins (e.g., bullatacin and bullatacine); a camptothecin (including synthetic analogue topotecan); bryostatin; calstactin; CC-1065 (including its adozelesin, carzelesin and bizelesin synthetic analogues); cryptophycins (artically cryptophycin 1 and cryptophycin 8); dolastatin; duocarmycin (including the synthetic analogues, KW-2189 and CBI-TM); eleutherobin; pancratistatin; a sordocytin; spongistatin; mustard mustards such as chlorambucil, chloromaphazine, chlorophosphamide, estramustine, ifosfamide, mechlorethamine, methloretamine oxde hydrochloride, melphalan, novembichin, phenersine, peridine, troforsofamid, uracil mustard; nitrosoureas such as carmustine, chlorozotocin, fotemustine, lomusetine, nimustine, raniurustine; antibiotics such as the enediyene antibiotics (e.g. calicheamicin, especially calicheamicin gamma11 and calicheamicin phi1, see, e.g., Agnew, Chem. Intl. Ed. Engl., 33: 183-186 (1994); dinemycin, including dinemycin A; bisphosphonates, such as clodronate; an esperamicin; as well as necarzinostatin chromophore and related chromoprotein enediyne antibiotic chromophores), aclacinomysins, actinomycin, authramycin, azaservere, bleomycins, caetinomycins, carablin, carcinomycin, carzinophilin, chromomycins, dactinomycins, daunorubicin, detorubicin, 6-diazo-5-oxo-L-norleucine, doxorubicin (Adramycin™) (including morpholinoo-doxorubicin, cyanomorpholinodoxorubicin, 2-pyrrolino-doxorubicin and deoxydoxorubicin), epirubicin, esorbucin, idarubicin, marcellomycin, mitomycins such as mitomycin C, mycophenolic acid, nogalamycin, olivomycins, plomycin, potfiromycin, puromycin, quela-mycin, rodorubicin, strepotrichin, streptogcin, tubercidin, ubenimex, zinostatin, zorubicin; anti-metabolites such as methotrexate and 5-fluorouracil (5-FU); folic acid analogues such as demopterin, methotrexate, pteropterin, trimetrexate; purine analogs such as fludarabine, 6-mercaptopurine, thiamiprine, tioguanine; pyrimidine analogues such as acitabine, azacitidine, 6-azauridine, cytarabine, doxifluridine, deoxyuridine, doxifluridine, enocitabine, floxuridine; androgens such as calusterone, dromostanolone propionate, epitiostanol, mepitiostane, testolactone; anti-adrenals such as aminolevulinic acid; eniluracil; amsacrine; bestrabucil; bisantrene; edatraxate; defofamine; demecolcine; diaziquone; elfornithine; ellipiutinum acetate; an epothilone; etoglucid; gallium nitrate; hydroxyurea; lentinan; lonidamine; maytansinoids such as maytansine and ansamitocins; mitoguazone, mitoxantrone, mopidamol; nitricrine; pentostatin; phenamet; pirarubicin; losoxantrone; podophyllinic acid; 2-ethylhydradize; procarbazine; PSK™; razoxane; rhizoxin; sizonofran; spirogermanium; tenuazonic acid; trioziqune; 2,2′,2″-trichlorotriethylamine; trichothecenes (e.g., T-2 toxin, verrucarin A, rokidin A and angiudine); uranthane; vindesine; dacarbazine; mannomustine; mitobronitol; mitolactil; pipobroman; gacysosine; cytosine arabinoside ("Ara-C"); cyclophosphamide; thiopeta; taxoids, e.g. paclitaxel (TAXOL™, Bristol Meyers Squibb Oncology, Princeton, N.J.) and docetaxel (TAXOTERE™, Rhone-Poulenc Rorer, Antony, France); chlorambucil; gemcitabine (Gemzar™); 6-thioguanine; mercaptopurine; methotrexate; platinum analogs such as cisplatin and carboplatin; vinblastane; platinum; etoposide (VP-16); ihosfamide; mitoxantrone; vancristine; vinorelbine (Navelbine™); novantrone; teniposide; edatraxate; daunomycin; aminopterin; xeloda; ibandronate; CPT-11; topoisomerase inhibitor RFS 2000; diffuromethylornithine (DMFO); retinoids such as retinoic acid; capetitamine; and pharmacologically acceptable salts, acids or derivatives of any of the above. Also included in the definition of "chemotherapeutic agent" are anti-hormonal agents that act to regulate or inhibit hormone action on tumors such as anti-estrogens and selective estrogen receptor modulators (SERMs), including, for example, tamoxifen (including Nolvadex™), raloxifene, droloxifene, 4-hydroxytamoxifen, trioxifene, keoxifene, LY117018, onapristone, and toremifene (Fareston™); inhibitors of the enzyme aromatase, which regulates estrogen production in the adrenal glands, such as, for example, 4(5)-imidazolones, aminoglu-
tethimide, megestrol acetate (Megace™), exemestane, formestane, fadrozole, vorozole (Rivisorm™), letrozole (Femara™), and anastrozole (Arimidex™); and anti-androgens such as flutamide, nilutamide, bicalutamide, leuprolide, and goserelin; and pharmaceutically acceptable salts, acids or derivatives of any of the above.

[0178] In some embodiments, the anti-neoplastic agent in combination with the LOX/LOXL modulator is a tyrosine kinase inhibitor. For example, ZD1839 (Iressa™ of AstraZeneca K.K.) shows a competitive effect for ATP in ATP binding site of EGFR (epidermal growth factor receptor) tyrosine kinase, and inhibits tyrosine kinase activity by inhibiting autophosphorylation of tyrosine kinase.

[0179] As a result, the anticancer effect is expressed by blocking an EGFR-equipping signal transduction (ligands such as epidermal growth factor (EGF) are bound to the extracellular domain of EGFR, followed by activation of EGFR tyrosine kinase in the intracellular domain, causing not only autophosphorylation of EGFR but also phosphorylation of various intracellular target proteins, then transducing the proliferation signals from the cancer cell surface to nucleus, resulting in proliferation, infiltration, metastasis, and angiogenesis of cancer cells.

[0180] IMC-C225 or cetuximab (Erbitux™) which is an EGFR-targeting monoclonal antibody recognizes the receptor part of EGFR on a cell membrane surface and inhibits the autophosphorylation of EGFR thereby inhibiting the tyrosine kinase activity. Herceptin, a monoclonal antibody against Her2/Neu which is homologous to EGFR, and imatinib mesylate (GLEEVEC™, formerly STI-571) can inhibit both tyrosine kinase activities of BCR-Ab1 and c-kit (non-patent document No. 2). Sorafenib (Nexavar™) is a small molecular inhibitor of Raf kinase, PDGF (platelet-derived growth factor), VEGF receptor 2 & 3 kinases and c-Kit.

[0181] As used herein, monoclonal antibodies against tumor antigens are antibodies elicited against antigens expressed by tumors and leukemic cells, for example, tumor-specific antigens. The monoclonal antibody also includes fully human and humanized antibody.

[0182] Other examples of therapeutic antibodies for cancer therapy include Trastuzumab (HERCEPTIN™); Overexpression of HER2 protein is associated with more aggressive disease and poorer prognosis in the clinic; Rituximab (RITUXAN™) that is raised against CD20 on lymphoma cells and selectively deplete normal and malignant CD20+ pre-B and mature B cells; Alemtuzumab (CAMPATH™), a monoclonal antibody that specifically targets CD52 antigen that is found on B and T lymphocytes and used for the treatment of chronic lymphocytic leukemia (CLL) and lymphoma; and Gemtuzumab zogamicin (MYLOTARG™), an antibody conjugate that combines a specific antibody against CD33 with a chemotherapeutic drug (zogamicin) and is indicated for the treatment of relapsed adult acute myelocytic leukemia.

[0183] In another embodiment, anti-angiogenic agent is combined with a LOX/LOXL inhibitor to treat cancer and other diseases associated with abnormal or undesirable angiogenesis. Examples of anti-angiogenic agents include, but are not limited to, retinoid acid and derivatives thereof, 2-methoxyestradiol, ANGIOSTATIN™, ENDOSTATIN™, suramin, squalamine, tissue inhibitor of metalloproteinase-1, tissue inhibitor of metalloproteinase-2, plasminogen activator inhibitor-1, plasminogen activator inhibitor-2, cartilage-derived inhibitor, paclitaxel, platelet factor 4, protamine sulphate (clupeine), sulphated chitin derivatives (prepared from queen crab shells), sulphated polysaccharide peptidoglycan complex (spg), staurosporine, modulators of matrix metabolism, including for example, proline analogs ((L-azetidine-2-carboxylic acid (LACA), cishydroxyproline, d,l-3,4-dehydroproline, thiaproline, α-diprydyl, β-aminoproprionitrile fumarate, 4-propyl-5-(4-pyridyl)-2-(3ht)-oxazolone; methotrexate, mitoxantrone, heparin, interferons, 2 macroglobulin-serum, chym-3, chymostatin, (3-cycloexetrin tetradecasulfate, eponemycin; fumagillin, gold sodium thiomalate, d-penicilamine (CDPT), beta-1-anticollegenase-serum,alpha.2-antiplasmin, bisantrene, lobenzarit disodium, n-2-carboxyphenyl-4-chloroanthonlic acid disodium or "CCA", thalidomide; angiostatic steroid, carboglycaminomazide; metalloproteinase inhibitors such as BB94. Other anti-angiogenesis agents include antibodies, for example, monoclonal antibodies against these angiogenic growth factors: bFGF, aFGF, FGF-5, VEGF isoforms, VEGF-C, HGF/SF and Ang-1/Ang-2. Ferrara N. and Alitalo, K. "Clinical application of angiogenic growth factors and their inhibitors" (1999) Nature Medicine 5:1359-1364. Other anti-angiogenesis agents may include inhibitors of VEGF transcription.

[0184] Exemplary anti-fibrotic agents include, but are not limited to the compounds such as β-aminoprobrontic acid (BAPN), as well as the compounds disclosed in U.S. Patent No. 4,965,288 to Palfreyman, et al., issued October 23, 1990, entitled "Inhibitors of lysyl oxidase, relating to inhibitors of lysyl oxidase and their use in the treatment of diseases and conditions associated with the abnormal deposition of collagen; U.S. 4,997,854 to Kagan, et al., issued March 5, 1990, entitled "Inhibitors of lysyl oxidase, relating to inhibitors of lysyl oxidase and their use in the treatment of diseases and conditions associated with the abnormal deposition of collagen; U.S. 5,252,608 (relating to 2-(1-naphthyloxymethyl)-3-fluoroallylamine); and U.S. Patent Application No. 2004/0248871, which are herein incorporated by reference. Exemplary anti-fibrotic agents also include the primary amines reacting with the carbonyl group of the active site of the lysyl oxidases, including those which produce, after binding with the carbonyl, a product stabilized by resonance, such as the following primary amines: ethylenediamine, hydrazine, phenylhydrazine, and their derivatives, semicarbazide, and urea derivatives, aminonitriles, such as β-aminoprobrontic acid (BAPN), or 2-
nitroethyamine, unsaturated or saturated haloamines, such as 2-bromo-ethylamine, 2-chloroethylamine, 2-trifluoroethyl-
amine, 3-bromopropylamine, p-halobenzylamines, selenohomocysteine lactone. In another embodiment, the anti-fibrotic
agents are copper chelating agents, penetrating or not penetrating the cells. Additional exemplary compounds include
indirect inhibitors such compounds blocking the aldehyde derivatives originating from the oxidative deamination of the
lysyl and hydroxylysyl residues by the lysyl oxidases, such as the thiolamines, for example, D-penicillamine, or its
analogues such as 2-amino-5-mercapto-5-methylhexanoic acid, D-2-amino-3-methyl-3-((2-acetamidoethyldithio)butano-
ic acid, p-2-amino-3-methyl-3-((2-acetamidoethyldithio)butanoic acid, sodium-4-((p-1-dimethyl-2-amino-2-carboxyethyl)
dithio)butane sulphinate, 2-acetamidoethyld-2-acetamidoethanethiol sulphanate, sodium-4-mercaptopbutanesulphinate
trihydrate.

6. Formulations, Kits and Routes of Administration

[0185] Therapeutic compositions comprising compounds identified as LOX/LOXL modulators using the disclosed
methods are also contemplated. In one embodiment, provided herein is a therapeutic composition for prophylaxis and
treatment of metastatic tumor growth, the composition comprising a therapeutically effective amount of a LOX/LOXL
inhibitor in a pharmaceutically acceptable carrier substance; wherein the inhibitor inhibits lysyl oxidase or lysyl oxidase-
like protein, such as LOXL-2, wherein the amount of the inhibitor is effective in preventing and treating metastatic tumor
growth. In another embodiment, provided herein is a therapeutic composition for prophylaxis and treatment of metastatic
tumor growth comprising a therapeutically effective amount of a LOX/LOXL inhibitor in a pharmaceutically acceptable
carrier in combination with radiation, surgery, chemotherapy, or an anticancer biologic which is not the LOX/LOXL inhibitor.

[0186] As used herein, the term "therapeutically effective amount" or "effective amount" refers to an amount of a
therapeutic agent that when administered alone or in combination with another therapeutic agent to a cell, tissue, or
subject is effective to prevent or ameliorate the disease condition or the progression of the disease. A therapeutically
effective dose further refers to that amount of the compound sufficient to result in amelioration of symptoms, e.g.,
treatment, healing, prevention or amelioration of the relevant medical condition, or an increase in rate of treatment,
treatment, healing prevention or amelioration of such conditions. When applied to an individual active ingredient administered
alone, a therapeutically effective dose refers to that ingredient alone. When applied to a combination, a therapeutically
effective dose refers to combined amounts of the active ingredients that result in the therapeutic effect, whether admin-
istered in combination, serially or simultaneously. For example, when in vivo administration of a LOX/LOXL antibody is
employed, normal dosage amounts may vary from about 10 ng/kg to up to 100 mg/kg of mammal body weight or more
per day, for example, about 1 µg/kg/day to 50 mg/kg/day, optionally about 100 µg/kg/day to 20 mg/kg/day, 500 µg/kg/day
to 10 mg/kg/day, or 1 mg/kg/day to 10 mg/kg/day, depending upon the route of administration.

[0187] Various pharmaceutical compositions and techniques for their preparation and use will be known to those of
skill in the art in light of the present disclosure. For a detailed listing of suitable pharmacological compositions and
associated administrative techniques one may refer to the detailed teachings herein, which may be further supplemented
by texts such as Remington: The Science and Practice of Pharmacy 20th Ed. (Lippincott, Williams & Wilkins 2003).

[0188] The compositions further include pharmaceutically acceptable materials, composition or vehicle, such as a
liquid or solid filler, diluent, excipient, solvent or encapsulating material, i.e., carriers. These carriers are involved in
transporting the subject chemical from one organ, or portion of the body, to another organ, or portion of the body. Each
carrier should be "acceptable" in the sense of being compatible with the other ingredients of the formulation and not
injurious to the patient. Some examples of materials which can serve as pharmaceutically-acceptable carriers include:
sugars, such as lactose, glucose and sucrose; starches, such as corn starch and potato starch; cellulose, and its
derivatives, such as sodium carboxymethyl cellulose, ethyl cellulose and cellulose acetate; powdered tragacanth; malt;
gelatin; tål; excipients, such as cocoa butter and suppository waxes; oils, such as peanut oil, cottonseed oil, safflower
oil, sesame oil, olive oil, corn oil and soybean oil; glycols, such as propylene glycol; polyols, such as glycercin, sorbitol,
mannitol and polyethylene glycol; esters, such as ethyl oleate and ethyl laurate; agar; buffering agents, such as mag-
nesium hydroxide and aluminum hydroxide; alginic acid; pyrogen-free water; isotonic saline; Ringer's solution; ethyl
alcohol; phosphate buffer solutions; and other non-toxic compatible substances employed in pharmaceutical formula-
tions. Wetting agents, emulsifiers and lubricants, such as sodium lauryl sulfate and magnesium stearate, as well as
coloring agents, release agents, coating agents, sweetening, flavoring and perfuming agents, preservatives and anti-
oxidants can also be present in the compositions.

[0189] Another aspect of the present disclosure relates to kits for carrying out the combined administration of the LOX/
LOXL modulator with the other therapeutic agent. In one embodiment, the kit comprises a LOX/LOXL inhibitor formulated
in a pharmaceutical carrier, and at least one therapeutic agent that is not the LOX/LOXL inhibitor, formulated as appro-
priate, in one or more separate pharmaceutical preparations.

[0190] The formulation and delivery methods will generally be adapted according to the site and the disease to be
treated. Exemplary formulations include, but are not limited to, those suitable for parenteral administration, e.g., intra-
venous, intra-arterial, intramuscular, or subcutaneous administration, including formulations encapsulated in micelles,
Agents as described herein can be incorporated into pharmaceutical compositions suitable for administration. Such compositions typically comprise the agent and a pharmaceutically acceptable carrier. Supplementary active compounds can also be incorporated into the compositions.

In yet other embodiments, the agents described herein are delivered locally. Localized delivery allows for the delivery of the agent non-systemically, for example, to the site of fibrosis, to reduce the entire body of the subject as compared to systemic delivery. Such local delivery may be achieved through the use of various medically implanted devices including, but not limited to, stents and catheters. Methods for coating, implanting, embedding, and otherwise attaching desired agents to medical devices such as stents and catheters are established in the art and contemplated herein.

Implanted stents have been used to carry medicinal agents, such as thrombolytic agents. U.S. Patent No. 5,163,952 discloses a thermal memory expanding plastic stent device formulated to carry a medicinal agent in the material of the stent itself. U.S. Patent No. 5,082,877 discloses a stent of a polymeric material which may have a coating associated with the delivery of compounds. Other patents which are directed to devices of the class utilizing biodegradable and bio-sorbable polymers include U.S. Patent No. 4,916,193, U.S. Patent No. 4,994,071. By way of example, U.S. Patent No. 5,304,121, discloses a coating applied to a stent consisting of a hydrogel polymer and a preselected compound such as collagen growth inhibitors or heparin. Methods of making a coated intravascular stent carrying a therapeutic material are described in U.S. Patent No. 5,464,650 wherein a polymer coating material is dissolved in a solvent and the therapeutic material dispersed in the solvent. The solvent is then evaporated after application.

U.S. Patent No. 6,120,536 describes additional types of coatings for use with a wide variety of prosthetic devices, including stents. Examples of additional medical or prosthetic devices that may be useful with the agents described herein include, but are not limited to, blood exchanging devices, vascular access ports, central venous catheters, cardiovascular catheters, extracorporeal circuits, vascular grafts, pumps, heart valves, and cardiovascular sutures. Regardless of detailed embodiments as described herein, applicability of the disclosure should not be considered limited with respect to implant design, implant location or materials of construction. The use of devices coated with the agents described herein, including stents and catheters, allows for the agents to be delivered to specific or localized sites. Such site-specific delivery can provide a means for use of dosages and drugs such as beta-aminopropionitrile (BAPN) and related compounds or other amine oxidase inhibitors (such as those small molecule inhibitors of LOX/LOXL described above) that are not otherwise amenable to systemic delivery due to solubility, systemic toxicity concerns, or other issues. By way of example, BAPN is known to be useful for LOX inhibition, but this compound is highly toxic, presenting problems for its effective use when administered systemically. The use of a stent, catheter, or other medical device for delivery of an active agent or compound such as BAPN permits use of the compound at effective dosages in a targeted or localized manner, thus decreasing the systemic toxic effects associated with such compounds and current routes of administration.

7. Composition Indications

The pharmaceutical formulations according to the present disclosure may be used to treat a wide variety of diseases. As used herein, "prevention" includes to prophylaxis, prevention of onset of symptoms, prevention of progression of a disease or disorder associated with fibrosis or correlated with LOX/LOXL activity. As used herein, "inhibition," "treatment," "treating," and "ameliorating" are used interchangeably and refer to, for example, stasis of symptoms, prolongation of survival, partial or full amelioration of symptoms, and partial or full eradication of a condition, disease or disorder associated with fibrosis or correlated with LOX/LOXL activity.

Compositions may be administered to a patient (e.g., a mammal such as a human or a non-human animal such as a primate, rodent, cow, horse, pig, sheep, etc.) in therapeutically effective amounts which are effective for producing a desired therapeutic effect by inhibiting a disease or disorder such as those described herein which are associated with fibrosis or LOX/LOXL activity, at a reasonable benefit/risk ratio applicable to any medical treatment. For human administration of the present compositions, the compositions may be formulated using methodology known by one of ordinary skill in the art. A therapeutically effective amount is an amount that achieves at least partially a desired therapeutic or prophylactic effect in an organ or tissue. In one example, the amount of an inhibitor of LOX/LOXL necessary to bring about prevention and/or therapeutic treatment of a disease or disorder is not fixed per se. The amount of an inhibitor of LOX/LOXL administered will vary with the type of disease or disorder, extensiveness of the disease or disorder, and size of the mammal suffering from the disease or disorder.

A response is achieved when the patient experiences partial or total alleviation, or reduction of signs or symptoms
of illness, and specifically includes, without limitation, prolongation of survival. The expected progression-free survival times may be measured in months to years, depending on prognostic factors including the number of relapses, stage of disease, and other factors. Prolonging survival includes without limitation times of at least 1 month, about at least 2 months, about at least 3 months, about at least 4 months, about at least 6 months, about at least 1 year, about at least 2 years, about at least 3 years, or more. Overall survival may also be measured in months to years. The patient's symptoms may remain static or may decrease.

[0199] Nonlimiting indications that may be treated using the pharmaceutical formulations of the present disclosure include those involving undesirable or uncontrolled cell proliferation. Such indications include benign tumors, various types of cancers such as primary tumors and tumor metastasis, restenosis (e.g., coronary, carotid, and cerebral lesions), hematological disorders, abnormal stimulation of endothelial cells (atherosclerosis), insults to body tissue due to surgery, abnormal wound healing, abnormal angiogenesis, diseases that produce fibrosis of tissue, macular degeneration, liver fibrosis, kidney fibrosis, lung fibrosis, scleroderma, atherosclerosis, and Alzheimer's disease, repetitive motion disorders, disorders of tissues that are not highly vascularized, and proliferative responses associated with organ transplants.

[0200] Generally, cells in a benign tumor retain their differentiated features and do not divide in a completely uncontrolled manner. A benign tumor is usually localized and nonmetastatic. Specific types of benign tumors that can be treated using the present disclosure include, but are not limited to, hemangiomas, hepatocellular adenoma, cavernous haemangioma, focal nodular hyperplasia, acoustic neuromas, neurofibroma, bile duct adenoma, bile duct cystoma, fibroma, lipomas, leiomyomas, mesotheliomas, teratomas, myxomas, nodular regenerative hyperplasia, trachomas and pyogenic granulomas.

[0201] In a malignant tumor cells become undifferentiated, do not respond to the body’s growth control signals, and multiply in an uncontrolled manner. The malignant tumor is invasive and capable of spreading to distant sites (metastasizing). Malignant tumors are generally divided into two categories: primary and secondary. Primary tumors arise directly from the tissue in which they are found. A secondary tumor, or metastasis, is a tumor which originated elsewhere in the body but has now spread to a distant organ. The common routes for metastasis are direct growth into adjacent structures, spread through the vascular or lymphatic systems, and tracking along tissue planes and body spaces (peritoneal fluid, cerebrospinal fluid, etc.)

[0202] Primary and metastatic tumors that may be treated by the methods disclosed herein may include, but not be limited to, lung cancer (including, but not limited to, lung adenocarcinoma, squamous cell carcinoma, large cell carcinoma, bronchioloalveolar carcinoma, non-small-cell carcinoma, small cell carcinoma, mesothelioma); breast cancer (including, but not limited to, ductal carcinoma, lobular carcinoma, inflammatory breast cancer, clear cell carcinoma, mucinous carcinoma, colorectal cancer (including, but not limited to, colon cancer, rectal cancer); anal cancer; pancreatic cancer (including, but not limited to, pancreatic adenocarcinoma, islet cell carcinoma, neuroendocrine tumors); prostate cancer; ovarian carcinoma (including, but not limited to, ovarian epithelial carcinoma or surface epithelial-stromal tumour including serous tumour, endometrioid tumor and mucinous cystadenocarcinoma, sex-cord-stromal tumor); liver and bile duct carcinoma (including, but not limited to, hepatocellular carcinoma, cholangiocarcinoma, hemangioma); esophageal carcinoma (including, but not limited to, esophageal adenocarcinoma and squamous cell carcinoma); non-Hodgkin’s lymphoma; bladder carcinoma; carcinoma of the uterus (including, but not limited to, endometrial adenocarcinoma, uterine papillary serous carcinoma, uterine clear-cell carcinoma, uterine sarcomas and leiomyosarcomas, mixed Mullerian tumors); glioma, glioblastoma, medullablastoma, and other tumors of the brain; kidney cancers (including, but not limited to, renal cell carcinoma, clear cell carcinoma, Wilms' tumor); cancer of the head and neck (including, but not limited to, squamous cell carcinomas); cancer of the stomach (including, but not limited to, stomach adenocarcinoma, gastrointestinal stromal tumor); multiple myeloma; testicular cancer; germ cell tumor; neuroendocrine tumor; cervical cancer; carcinoids of the gastrointestinal tract, breast, and other organs; and signet ring cell carcinoma.

[0203] Mesenchymal tumors may include, but not be limited to, sarcomas, fibrosarcomas, haemangiomata, angiomas, haemangiopericytoma, pseudangiomatous stromal hyperplasia, myofibroblastoma, fibromatosis, inflammatory myofibroblastic tumour, lipoma, angiolipoma, granular cell tumour, neurofibroma, schwannoma, angiosarcoma, liposarcoma, rhabdomyosarcoma, osteosarcoma, leiomyoma, and leiomyosarcoma.

[0204] Specific types of cancers or malignant tumors, either primary or secondary, that can be treated using this disclosure also include, but are not limited to, skin cancer, bone cancer, brain cancer, cancer of the larynx, gall bladder, pancreas, parathyroid, thyroid, adrenal, neural tissue, head and neck, bronchi, basal cell carcinoma, squamous cell carcinoma of both ulcerating and papillary type, metastatic skin carcinoma, osteo sarcoma, Ewing's sarcoma, vegeta
cell sarcoma, myeloma, giant cell cancer, small-cell lung tumor, gallstones, islet cell tumor, primary brain tumor, acute and chronic lymphocytic and granulocytic tumors, hairy-cell tumor, adenoma, hyperplasia, medullary carcinoma, phaeochromocytoma, mucosal neurenomas, intestinal ganglioneuromas, hyperplastic corneal nerve tumor, marfanoid habitus tumor, seminoma, ovarian tumor, leiomyomater tumor, cervical dysplasia and in situ carcinoma, neuroblastoma, retinoblastoma, soft tissue sarcoma, malignant carcinoid, topical skin lesion, mycosis fungoides, rhabdomyosarcoma, Kaposi's sarcoma, osteogenic and other sarcoma, malignant hypercalcemia, renal cell tumor, polycythermia vera, adenoscar
coma, glioblastoma multiforma, leukemias, lymphomas, malignant melanomas, epidermoid carcinomas, and other car-

27
zymes that break down matrices and cross-linked collagen or elastin appear to function more slowly or less efficiently. Expression of specific lysyl oxidases may be associated with different stages of the inflammatory response associated with cardiac ischemic events.

Cardiovascular Fibrosis

Compositions, methods, systems, medical devices and kits are provided herein for the treatment or prevention of cardiovascular or cardiac fibrosis, for example, associated with cardiovascular diseases such as congestive heart failure, cardiomyopathy, post-myocardial infarction defects in heart function, hypertensive heart disease (HHD), myocardial infarction (MI), atherosclerosis, restenosis (e.g. coronary, carotid, and cerebral lesions), and heart disease associated with cardiac ischemic events.

Expression of specific lysyl oxidases may be associated with different stages of the inflammatory response and wound healing after myocardial infarction. By specifically inhibiting the particular lysyl oxidase/s associated with the downstream fibrotic response, the detrimental consequences of cardiac remodeling and wound healing can be avoided, while allowing the immediate post-MI repair/healing process to occur.

The post MI-healing response can induce expression of LOX/LOXL but if this process continues unchecked, excessive cross-linking leads to extracellular matrix remodeling or fibrosis that results in cardiac dysfunction. The enzymes that break down matrices and cross-linked collagen or elastin appear to function more slowly or less efficiently and are outpaced by crosslinking events. As LOX/LOXL also plays a role in epithelial-mesenchymal transition (EMT), this contributes further to cardiomyocyte remodeling and cardiomyocyte hypertrophy, in addition to matrix remodeling.

Initial reparative fibrosis induced by the MI may be helpful (e.g., prevents aneurysm and related damage) and...
may be allowed to proceed unhindered. However, while not wishing to be bound to a particular theory or mechanism of action, the inventors believe that anti-LOX/LOXL treatment initiated following this reparative fibrosis phase could attenuate reactive (mal-adaptive) fibrosis that leads to cardiac dysfunction. For example, anti-LOX/LOXL treatment may be initiated 2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 36, 48 or more hours after MI, inclusive of all integers and times in between. Additionally, anti-LOX/LOXL treatment may be initiated 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, or more days after MI. Similarly, increases in blood pressure (hypertension) result in increased collagen deposition and reduced protein degradation in cardiac tissue. (Berk et al., J. Clin. Invest., 117(3): 568-575 (2007)). Anti-LOX/LOXL treatment initiated following diagnosis and/or establishment of hypertensive heart disease or hypertension can prevent, reduce, or ameliorate fibrosis associated with hypertension. Such anti-LOX/LOXL treatment is initiated 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14 or more days after increases in hypertension or systemic blood pressure are diagnosed or detected.

[0218] In some embodiments, biomarkers may be used to determine when an inappropriate level of cross-linking might be occurring: LOX levels have been shown to correlate with C reactive protein (CRP), a commonly used biomarker, and treatment may begin when CRP levels are elevated above appropriate normal levels. More directly, methods and test kits exist to measure the release of cross-linked collagen telopeptides in urine or blood. Elevated levels of these collagen fragments may indicate a transition from reparative fibrosis to reactive (mal-adaptive) fibrosis. In addition, measures of cardiac function and output, including those associated with efficient contraction of the ventricle, may be made.

[0219] In some embodiments, a limited duration of treatment is envisioned. Treatment should typically be sustained only long enough to prevent or attenuate reactive fibrosis to prevent or reduce cardiac dysfunction. For example, short-lived Fab antibody fragments are used when shorter durations of treatment are desired. Alternatively, full-length antibodies that have a longer half-life in serum may be used, with limited dosing over 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, or more weeks, inclusive of all days in between. Standard tests of cardiac function may be used to monitor progress and adjust dosing as necessary, along with assessment of relevant biomarkers discussed above. Limited duration of treatment adds to the safety of this approach.

[0220] The indications for the administration of the compositions described herein also include fibroses found outside of cardiovascular indications. Fibrosis is the abnormal accumulation of fibrous tissue that can occur as a part of the wound-healing process in damaged tissue. Such tissue damage may result from physical injury, inflammation, infection, exposure to toxins, as well as other causes. Examples of fibrosis include dermal scar formation, keloids, liver fibrosis, lung fibrosis (e.g., silicosis, asbestosis), and kidney fibrosis (including diabetic nephropathy and glomerulosclerosis). Additionally, fibrosis and deposition of collagen have been implicated in the formation of β-amyloid plaques, thus contributing to the development and progression of Alzheimer’s disease. The compositions described herein are also contemplated for the treatment, prevention, and/or amelioration of the following fibrotic conditions.

Dermal scar and keloid formation

[0221] Dermal scar and keloid formation are known to involve excessive collagen deposition and/or dysregulation of collagen deposition. This deviation from normal fibroblast remodeling of injured dermal tissue can result in thick and unsightly scarring. Keloids are known to be, in part, the result of dysregulated wound healing and subsequent elevated collagen deposition. Keloids, unlike the scars seen in normal wound healing, do not fade or regress over time. Though keloids are typically benign dermal tumors, they are unsightly and can accumulate into more problematic skin deformations and/or lesions. (Appleton, I., et al., Apoptosis, Necrosis, and Proliferation: Possible Implications in the Etiology of Keloids, Am. J. Pathol., 149(5): 1441 - 1447 (1996)). The accumulation of collagen in the skin is also implicated in scleroderma, a generalized term for numerous conditions of thickening or hardening of dermal tissue, where the common element is the overproduction or dysregulation of collagen in the dermal tissues by fibroblasts. (Akagi, A. et al., Expression of Type XVI Collagen in Human Skin Fibroblasts: Enhanced Expression in Fibrotic Skin Disease, J. Invest. Dermatol., 113: 246-250 (1999)). Given the central role of collagen deposition in fibrotic skin diseases such as scleroderma and keloid formation, the compositions described herein are useful in the prevention, treatment, and/or amelioration of fibrotic skin diseases, including but not limited to, scleroderma and keloid formation.

Liver fibrosis

[0222] Fibrosis of the liver is implicated in the pathology of numerous hepatic diseases. As previously noted, fibrosis occurs as a complication of haemochromatosis, Wilson’s disease, alcoholism, schistosomiasis, viral hepatitis, bile duct obstruction, exposure to toxins, and metabolic disorders. Left unchecked, hepatic fibrosis progresses to cirrhosis (defined by the presence of encapsulated nodules), liver failure, and death.

[0223] Liver fibrosis, including, but not limited to, cirrhosis, and associated conditions such as chronic viral hepatitis, non-alcoholic fatty liver disease (NAFLD), alcoholic steatohepatitis (ASH), non-alcoholic steatohepatitis (NASH), primary biliary cirrhosis (PBC), biliary cirrhosis, and autoimmune hepatitis, may be treated by the compositions and methods disclosed herein.
The chronic insults to the liver from such sources as parasites and viral infection (e.g. HBV, HCV, HIV, schistosomiasis) or the long term stress from alcohol consumption typically result in remodeling of the liver, presumably to encapsulate the damaged area and protect the remaining liver tissue from damage. (Li and Friedman, Gastroenterol. Hepatol. 14: 618-633, 1999). Liver fibrosis results in extracellular matrix changes, including 3-10 fold increases in total collagen content and replacement of the low density basement membrane with high-density matrix, which impair the metabolic and synthesis function of hepatocytes, hepatic stellate cells and endothelial cells. (Girogescu, M., Non-invasive Biochemical Markers of Liver Fibrosis, J. Gastrointestin. Liver Dis., 15(2): 149-159 (2006)). The compositions described herein are thus useful for the prevention, treatment, and/or amelioration of fibrotic liver diseases, and such use is contemplated herein.

Kidney fibrosis

Like liver fibrosis, kidney fibrosis can result from various diseases and insults to the kidneys. Examples of such diseases and insults include chronic kidney disease, metabolic syndrome, vesicoureteral reflux, tubulointerstitial renal fibrosis, diabetes (including diabetic nephropathy), and resultant glomerular nephritis (GN), including, but not limited to, focal segmental glomerulosclerosis and membranous glomerulonephritis, mesangiocapillary GN. It has become recognized that metabolic syndrome is a cluster of abnormalities including diabetic hallmarks such as insulin resistance, as well as central or visceral obesity and hypertension. In nearly all cases, dysregulation of glucose results in the stimulation of cytokine release and upregulation of extracellular matrix deposition. Additional factors contributing to chronic kidney disease, diabetes, metabolic syndrome, and glomerular nephritis include hyperlipidemia, hypertension, and proteinuria, all of which result in further damage to the kidneys and further stimulate the extracellular matrix deposition. Thus, regardless of the primary cause, insults to the kidneys may result in kidney fibrosis and the concomitant loss of kidney function. (Schena, F. and Gesualdo, L., Pathogenic Mechanisms of Diabetic Nephropathy, J. Am. Soc. Nephrol., 16: S30-33 (2005); Whaley-Connell, A., and Sower, J.R., Chronic Kidney Disease and the Cardiometabolic Syndrome, J. Clin. Hypert., 8(8): 546-48 (2006)). The compositions described herein are thus useful for the prevention, treatment, and/or amelioration of fibrotic kidney diseases (chronic kidney disease, diabetic nephropathy, glomerular nephritis, metabolic syndrome), and such use is contemplated herein.

Lung fibrosis

Fibrosis of the lung includes many syndromes and diseases. Exemplary diseases include idiopathic pulmonary fibrosis (IPF), idiopathic interstitial pneumonia, and acute respiratory distress syndrome (ARDS). Lung fibrosis may also include, but not be limited to, cryptogenic fibrosing alveolitis, chronic fibrosing interstitial pneumonia, interstitial lung disease (ILD), and diffuse parenchymal lung disease (DPLD). The pathogenesis of most lung fibroses, including the aforementioned diseases are not well understood, however all are characterized by an influx of inflammatory cells and a subsequent increase in the synthesis and deposition of collagen-rich extracellular matrix. (Chua et al., Am J. Respir. Cell. Mol. Biol., 33:9-13 (2005); Tzortzaki et al., J. Histochem. & Cytochem., 54(6): 693-700 (2006); Armstrong et al., Am. J. Respir. Crit. Care Med., 160: 1910-1915 (1999)). Given the identified role of increased collagen and extracellular matrix deposition in lung fibroses, the compositions described herein are useful for the prevention, treatment, and/or amelioration of lung fibroses by the inhibition of LOX/LOXL.

Alzheimer's disease

Alzheimer’s disease is a progressive neurodegenerative disorder characterized by neuronal loss due to accumulation of amyloid-beta plaques, and lysyl oxidase activity is also known to be increased in Alzheimer’s disease. (Gilad et al., Neurosci. Lett., 376(3): 210-13 (2005)). Amyloid-beta contains multiple lysine residues which represent targets for LOX/LOXL activity, thus inhibition of LOX/LOXL can treat, prevent, or ameliorate the accumulation of amyloid plaques in Alzheimer’s disease. Amyloid-beta plaques are also known to consist of additional proteins. One such protein contributing to the formation and content of amyloid-beta plaques is a collagen protein termed CLAC-P. CLAC-P is similar to collagen Type XIII in structure but is distributed in neurons. CLAC-P binds with amyloid-beta and contributes to the formation of amyloid-beta plaques. (Soederberg et al., J. Biol. Chem., 280(2): 1007-1015 (2005)). The compositions described herein are thus useful for the prevention, treatment, and/or amelioration of Alzheimer’s disease, including, but not limited to, the prevention of amyloid-beta plaque formation as well as the reduction in the persistence of amyloid-beta plaques.

Abnormal angiogenesis that may be treated or prevented by using the methods and compositions described herein include abnormal angiogenesis accompanying rheumatoid arthritis, ischemic-reperfusion related brain edema and injury, cortical ischemia, ovarian hyperplasia and hypervascularity, (polycystic ovary syndrome), endometriosis,
Diseases associated with abnormal angiogenesis require or induce vascular growth. For example, corneal fibroplastic), macular degeneration, corneal graft rejection, neurovascular glaucoma and Oster Webber syndrome. Diseases associated with undesired or abnormal angiogenesis. The method comprises administering to a patient suffering from undesired or abnormal angiogenesis a LOX/LOXL inhibitor in combination with an anti-neoplastic agent or anti-angiogenic agent that is not the LOX/LOXL inhibitor. The particular dosage of these agents required to inhibit angiogenesis and/or angiogenic diseases may depend on the severity of the condition, the route of administration, and related factors that can be decided by the attending physician. Generally, accepted and effective daily doses are the amount sufficient to effectively inhibit angiogenesis and/or angiogenic diseases.

According to this embodiment, the pharmaceutical formulations of the present disclosure may be used to treat a variety of diseases associated with undesirable angiogenesis such as retinal/choroidal neovascularization and corneal neovascularization. Examples of retinal/choroidal neovascularization include, but are not limited to, Bests diseases, myopia, optic pits, Stargars diseases, Pagets disease, vein occlusion, artery occlusion, sickle cell anemia, sarcoid, syphilis, pseudoxanthoma elastica carotid atherosclerotic diseases, chronic uveitis/vitritis, mycobacterial infections, Lyme's disease, systemic lupus erythematosus, retinopathy of prematurity, Eales disease, diabetic retinopathy, macular degeneration, Bechets diseases, infections causing a retinitis or chroiditis, presumed ocular histoplasmosis, pars planitis, chronic retinal detachment, hyperviscosity syndromes, toxoplasmatis, trauma and post-laceration complications, diseases associated with rubesis (neovascularization of the angle) and diseases caused by the abnormal proliferation of fibrovascular or fibrous tissue including all forms of proliferative vitreoretinopathy. Examples of corneal neovascularization include, but are not limited to, epidemic keratoconjunctivitis, Vitamin A deficiency, contact lens overwear, atopic keratitis, superior limbic keratitis, pterygium keratitis sicca, sjogrens, acne rosacea, phylectenulosis, diabetic retinopathy, retinopathy of prematurity, corneal graft rejection, Mooren ulcer, Terrien's marginal degeneration, marginal keratolysis, polyparteritis, Wegener sarcoidosis, Scleritis, periphigoid radial keratotomy, neovascular glaucoma and retrolental fibroplasia, syphilis, Mycobacterium infections, lipid degeneration, chemical bums, bacterial ulcers, fungal ulcers, Herpes simplex infections, Herpes zoster infections, protozoan infections and Kaposi sarcoma.

In yet another embodiment, the pharmaceutical formulations of the present disclosure may be used for treating chronic inflammatory diseases associated with abnormal angiogenesis. The method comprises administering to a patient suffering from a chronic inflammatory disease associated with abnormal angiogenesis a LOX/LOXL inhibitor in combination with an anti-neoplastic agent or anti-angiogenic agent that is not the LOX/LOXL inhibitor. The chronic inflammation depends on continuous formation of capillary sprouts to maintain an influx of inflammatory cells. The influx and presence of the inflammatory cells produce granulomas and thus, maintains the chronic inflammatory state. Inhibition of angiogenesis using the pharmaceutical formulations of the present disclosure may prevent the formation of the granulomas, thereby alleviating the disease. Examples of chronic inflammatory disease include, but are not limited to, inflammatory bowel diseases such as Crohn's disease and ulcerative colitis, psoriasis, sarcoidosis, and rheumatoid arthritis.

Inflammatory bowel diseases such as Crohn's disease and ulcerative colitis are characterized by chronic inflammation and angiogenesis at various sites in the gastrointestinal tract. For example, Crohn's disease occurs as a chronic transmural inflammatory disease that most commonly affects the distal ileum and colon but may also occur in any part of the gastrointestinal tract from the mouth to the anus and perianal area. Patients with Crohn's disease generally have chronic diarrhea associated with abdominal pain, fever, anorexia, weight loss and abdominal swelling. Ulcerative colitis is also a chronic, nonspecific, inflammatory and ulcerative disease arising in the colonic mucosa and is characterized by the presence of bloody diarrhea. These inflammatory bowel diseases are generally caused by chronic granulomatous inflammation throughout the gastrointestinal tract, involving new capillary sprouts surrounded by a cylinder of inflammatory cells. Inhibition of angiogenesis by the pharmaceutical formulations of the present disclosure should inhibit the formation of the sprouts and prevent the formation of granulomas. The inflammatory bowel diseases also exhibit extra intestinal manifestations, such as skin lesions. Such lesions are characterized by inflammation and angiogenesis and can occur at many sites other the gastrointestinal tract. Inhibition of angiogenesis by the pharmaceutical formulations of the present disclosure should reduce the influx of inflammatory cells and prevent the lesion formation.

Sarcoidosis, another chronic inflammatory disease, is characterized as a multi-system granulomatous disorder. The granulomas of this disease can form anywhere in the body and, thus, the symptoms depend on the site of the granulomas and whether the disease is active. The granulomas are created by the angiogenic capillary sprouts providing a constant supply of inflammatory cells. By using the pharmaceutical formulations of the present disclosure to inhibit angiogenesis, such granulomas formation can be inhibited. Psoriasis, also a chronic and recurrent inflammatory disease, is characterized by papules and plaques of various sizes. Treatment using the pharmaceutical formulations of the present
disclosure should prevent the formation of new blood vessels necessary to maintain the characteristic lesions and provide the patient relief from the symptoms.

Rheumatoid arthritis (RA) is also a chronic inflammatory disease characterized by non-specific inflammation of the peripheral joints. It is believed that the blood vessels in the synovial lining of the joints undergo angiogenesis. In addition to forming new vascular networks, the endothelial cells release factors and reactive oxygen species that lead to pannus growth and cartilage destruction. The factors involved in angiogenesis may actively contribute to, and help maintain, the chronically inflamed state of rheumatoid arthritis. Treatment using the pharmaceutical formulations of the present disclosure alone or in conjunction with other anti-RA agents may prevent the formation of new blood vessels necessary to maintain the chronic inflammation and provide the RA patient relief from the symptoms.

8. Diagnosis of Diseases

The present disclosure also provides methods for diagnosing, monitoring, staging or detecting the diseases described above by using agents that recognize different forms of LOX or LOXL. For example, as described above, antibodies against different forms of LOX or LOXL, the preproprotein, secreted, mature form, can be used for these purposes.

As described above, mature LOX or LOXL is cleaved and can be detected by virtue of it changes in molecular weight (immunoblot) or by use of antibodies that detect the uncleaved vs. cleaved form of LOX/LOXL, along with cellular localization by using various detection methods such as immunohistochemistry (IHC).

It is believed that the extracellular matrix and conditioned medium (e.g., See Example 4) should contain proteolytically processed LOX or LOXL whereas uncleaved LOX/LOXL should be localized intracellularly. Some cleaved LOX/LOXL may also be detected inside the cell as a consequence of uptake from the extracellular space.

Samples from individuals can be collected and analyzed by determining inactive or active LOX levels or different forms of LOX/LOXL levels. This analysis may be performed prior to the initiation of treatment using lysyl oxidase-specific therapy to identify tumors having elevated active LOX/LOXL expression or activity. Such diagnosis analysis can be performed using any sample, including but not limited to cells, protein or membrane extracts of cells, biological fluids such as sputum, blood, serum, plasma, or urine, or biological samples such as tissue samples, formalin-fixed or frozen tissue sections.

Any suitable method for detection and analysis of inactive and/or active LOX/LOXL can be employed. As used herein, the term "sample" refers to a sample from a human, animal, or to a research sample, e.g., a cell, tissue, organ, fluid, gas, aerosol, slurry, colloid, or coagulated material. The sample may be tested in vivo, e.g., without removal from the human or animal, or it may be tested in vitro. The sample may be tested after processing, e.g., by histological methods. The term "sample" may also refer to a cell, tissue, organ, or fluid that is freshly taken from a human or animal, or to a cell, tissue, organ, or fluid that is processed or stored.

In one embodiment, methods are provided for diagnosing cancer metastasis in a subject, comprising assessing active LOX or LOXL levels or activity in the blood, whereby a change in active LOX or LOXL levels or activity in the blood in comparison with a reference sample, indicates the presence of metastatic tumor growth. In some instances, the active LOX or LOXL levels or activities in the blood may be lower than those when measured earlier, which may indicate that the subject is at a greater risk of cancer metastasis; that the cancer has metastasized; or that cancer metastasis has increased.

In another embodiment, methods are provided for diagnosing cancer metastasis in a subject having a tumor, comprising assessing active LOX or LOXL levels or activity in the tumor, whereby a change in active LOX or LOXL levels or activity in the tumor in comparison with a reference sample indicates the presence of metastatic tumor growth. In some instances, the active LOX or LOXL levels or activities in the tumor may be higher than those when measured earlier, which may indicate that the subject is at a greater risk of cancer metastasis; that the cancer has metastasized; or that cancer metastasis has increased.

The reference sample may derive from the same subject, taken from the same tumor at a different time point or from another site of the body, or from another individual.

Measurement of active LOX or LOXL levels may take the form of an immunological assay, which detects the presence of active LOX or LOXL protein with an antibody to the protein, for example, an antibody specifically binding to active or secreted LOX or LOXL.

Immunostains also can be used in conjunction with laser induced fluorescence (see, for example, Schmalzing and Nashabeh, Electrophoresis 18:2184-93 (1997)); Bao, J. Chromatogr. B. Biomed. Sci. 699:463-80 (1997), each of which is incorporated herein by reference). Liposome immunoassays, such as flow-injection liposome immunoassays and liposome immunosensors (Rongen et al., J. Immunol. Methods 204:105-133 (1997), also can be used to determine active LOX or LOXL levels according to a method of the disclosure). Immunoassays, such as enzyme-linked immuno-sorbent assays (ELISAs), are useful in the methods provided herein. A radioimmunoassay also can be useful for determining whether a sample is positive for active LOX or LOXL or for determining the level of active LOX or LOXL. A
radioimmunoassay using, for example, an iodine-125 labeled secondary antibody, may be used.

[0248] In addition, one may measure the activity of active LOX or LOXL, thus ignoring the amount of inactive enzyme. Enzymatic activity of active LOX or LOXL may be measured in a number of ways, using a soluble elastin or soluble collagen with labeled lysine as a substrate. Details of an activity assay are given in Royce et al., "Copper metabolism in mottled mouse mutants. The effect of copper therapy on lysyl oxidase activity in brindled (Mobr) mice," Biochem J. 1982 February 15; 202(2): 369-371. Chromogenic assays may be used. One is described in Palamakumbura, et al. "A fluorometric assay for detection of lysyl oxidase enzyme activity in biological samples," Anal Biochem. 2002 Jan 15; 300(2):245-51.

[0249] Also provided here is a method for monitoring a subject's response to a therapy including a modulator of LOX/LOXL such as the treatment of cancer, tumors, and fibrotic diseases. The method comprises: detecting a change in the level C-reactive protein, or other acute-phase reactants, in the subject after administration of a modulator of LOX or LOXL to the subject, wherein the change indicates that the LOX or LOXL modulator has a therapeutic effect on the subject. A C-reactive protein is an important pharmacodynamic marker for systemic inflammation. Furthermore, C-reactive protein is thought to enhance LOX expression (Li et al., Circulation Research; (2004) 95:877). Thus, without being bound by theory, a reduced level of C-reactive protein (e.g., in the blood sample of the subject) as compared to that prior to the administration of the LOX or LOXL inhibitor can be indicative of the subject's response to the therapy using an inhibitor of LOX or LOXL. Methods includes including monitoring an increase or decrease in levels of C-reactive protein, which would be indicative of the subject's response to the therapy.

[0250] In another embodiment, methods are provided for monitoring a subject's response to a therapy including a modulator of LOX/LOXL such as the treatment of cancer, tumors, and fibrotic diseases. The method comprises: detecting a change in the level of collagen telopeptides or hydroxyproline content in the subject after administration of a modulator of LOX or LOXL to the subject, wherein the change indicates that the LOX or LOXL modulator has a therapeutic effect on the subject. The change can be an increase or decrease. For example, a decrease in collagen telopeptides or hydroxyproline content can be indicative of a therapeutic effect.

[0251] Although exemplary embodiments of the present disclosure have been described and depicted, it will be apparent to the artisan of ordinary skill that a number of changes, modifications, or alterations to the disclosure as described herein may be made, none of which depart from the spirit of the present disclosure. All such changes, modifications, and alterations should therefore be seen as within the scope of the present disclosure. The following examples are offered to illustrate but not to limit the disclosure.

EXAMPLES

Example 1: EMT/MET Assay

[0252] To detect whether a cell is in an EMT or MET state, cells are stained with antibodies specific to cellular protein markers for epithelial or mesenchymal states such as E-cadherin, vimentin, fibronectin, and phalloidin to detect F-actin (FIGURE 4).

Rhodamine Phalloidin Staining Protocol:

[0253] Cells were seeded 24 hours prior to day of staining; cells should be approximately 80% confluent 24 hours later in an 8-chambered slide. The next day, the media was aspirated and the chambers were rinsed with 1X PBS. Cells were then fixed with 4% Parafomaldehyde (PFA) for 20 minutes at room temperature and then rinsed once with 1X PBS. For permeabilization, the cells were treated with 0.5% Saponin (JT Baker, Phillipsburg, NJ) in PBS for 5 minutes at room temperature. The chambers were carefully rinsed once with 1X PBS and a 1:100 dilution of rhodamine phalloidin (Invitrogen, Carlsbad, Ca) in PBS was added to the cells and incubated for 15 minutes at room temperature. The chambers were rinsed two times with 1X PBS and the slides were mounted with Vectashield (Vector Laboratories, Burlingame, Ca).

E-Cadherin Staining Protocol:

[0254] Cells were seeded 24 hours prior to day of staining; cells should be approximately 80% confluent the next day in an 8-chambered slide. The next day, the media was aspirated and the chambers were rinsed with 1X PBS. Cells were then fixed with ice cold methanol and then incubated for 2 minutes in -20°C. The cells were rinsed once with 1X PBX and 1μg/ml of E-cadherin Ab (Calbiochem, Gibbstown, NJ) was added to the slide chambers. The slides were then incubated at 37°C for 1 hour. After carefully rinsing the chambers one time with 1X PBS, the secondary Ab (anti-mouse IgG by3 conjugated, Jackson Immuno Research, West Grove, Pa) was added and incubated at room temperature for 30-45 minutes. The chambers were rinsed two times with 1X PBS and mounted with Vectashield (Vector Laboratories,
Example 2: Assay for LOX/LOXL inhibitors that reduce EMT/promote MET in cells endogenously expressing significant levels of LOX/LOXL

[0255] BT-549, Hs5788t, MDA-MB-231, or NCI-H226 cells express significant levels of LOX/LOXL and are in an EMT or EMT-like state. The cells are seeded onto 8-well chamber glass slides (Nalgene Nunc International, Rochester, New York) at ~25-50% confluence. The cells are incubated for 18h under hypoxic (2% oxygen), anoxic (0.02% oxygen), or normoxic (21% oxygen) conditions.

[0256] LOX/LOXL inhibitors (e.g., anti-LOX/LOXL antibody, LOX/LOXL siRNA, LOX/LOXL shRNA, small molecule inhibitors, such as (APN or D-pencillamine) and controls (e.g., LOX/LOXL sense oligonucleotides, irrelevant control antibody, small molecule vehicle such as DMSO) are added to the cell culture media. LOX/LOXL levels are determined by RT-PCR and immunoblot analysis.

[0257] After 48-72 hours, cells are stained according to Example 1. Cells transfected with LOX/LOXL sense oligonucleotides should maintain EMT characteristics of positive vimentin or fibronectin staining with low levels of E-cadherin staining and an elongated and remodeled actin cytoskeleton as revealed by phalloidin staining of F-actin. Cells treated with candidate LOX/LOXL inhibitors that do not effectively target LOX/LOXL to effect MET induction of the EMT cells should also maintain these EMT characteristics.

[0258] Cells treated with LOX/LOXL inhibitors should reduce EMT characteristics and manifest MET characteristics of increased E-cadherin staining and reduced or negligible vimentin or fibronectin staining. The rhodamine-phalloidin staining of these cells should reveal a more compact and regular actin cytoskeleton.

[0259] Invasion/migration assays are also used to assess EMT and MET phenotypes of the cells, as increased invasiveness and migratory capacity are associated with EMT. (See e.g. Bedogni et al., Cancer Res. 64: 2552-2560 (2004)) Cells are serum deprived for 24h then 10⁴ - 10⁵ cells are seeded in triplicate on coated and uncoated inserts (for example, Matrigel™ coated inserts from BD Biosciences), and incubated under normoxic or oxygen-deprived conditions for 24h (for example, LOX/LOXL expression can differ under normoxic/hypoxic conditions as shown in FIGURE 33). Treatments with LOX/LOXL inhibitors and controls are continued throughout the experiment.

[0260] The cells maintaining an EMT state should be invasive and migratory, and able to invade through the Matrigel™-coated inserts, or migrate across other surface-modified inserts, more readily in comparison to MET cells. A similar analysis is conducted using a wound-healing or scratch assay, in which a scratch is made using a pipet tip in a confluent lawn of cells. The scratch is monitored over 24 - 96h using a microscope. Cells in a state of EMT that are more invasive and migratory should fill the scratch more rapidly than less invasive or migratory cells.

[0261] Those LOX/LOXL inhibitors that reduce EMT and promote MET are selected as candidates for further development.

[0262] As depicted in FIGURES 26A and B a screen for mAbs that inhibit cell invasion and migration that was performed. Final Pep2 supernatants screened were purified and concentrated (MO63 to MO82, 50ng and 200ng for each). MDA MB 231 cells were serum deprived for 24 hours and were seeded at 20,000 cells/well in serum free media. Cells were treated with triplicate sets of 50 ng and 200ng of antibody sera and were incubated for 48 hours. Invasive cells were dyed with calcein AM and the fluorescence was measured on a 96 well fluorescent reader (485 nm excitation, 520 emission).

Example 3: Assay for LOX/LOXL inhibitors that reduce EMT/promote MET with cells transfected with LOX/LOXL

[0263] MDCK, MCF-7, or SW620 cells do not express significant levels of LOX/LOXL and are not in an EMT state. The cells are transfected with plasmids that express LOX/LOXL to induce EMT in the cells (see for example FIGURE 6). The transfected cells are incubated for 18h under normoxic (21% oxygen), hypoxic (2% oxygen) or anoxic (0.02% oxygen) conditions. Expression of LOX/LOXL levels are determined by RT-PCR and immunoblot analysis.

[0264] The transfected cells are treated with LOX/LOXL inhibitors and controls, MET/EMT status determined as described in Example 2. Expression of LOX/LOXL levels of treated cells are determined by RT-PCR and immunoblot analysis.

[0265] Effective LOX/LOXL inhibitors should prevent the EMT state, or induce MET, of the transfected cells. (FIGURE 7) Transfected cells treated with LOX/LOXL sense oligonucleotides should be in an EMT state as should transfected cells without any treatment, or treatment with controls such as an irrelevant control antibody. The EMT/MET state of the treated transfected cells are analyzed as described in Example 1. The cells can also be analyzed using invasion and/or migration assays as described in Example 2.

[0266] Those LOX/LOXL inhibitors that reduce EMT and promote MET are selected as candidates for further development.
Example 4: Assay for LOX/LOXL inhibitors that reduce EMT/promote MET with cells treated with Conditioned Media (CM)

Making CM from CHO Cells:

[0267] CHO-Loxl2 cells were seeded into a T175 flask with a volume of 25 mls of media (MEM + 10% FBS, complete). 48 hours later, the media was replaced with 20mls of SFMII media (cells were 90-95% confluent at this point). The media was collected 72 hours later and filtered in a.22uM polyethylene filter. The filtered media was concentrated 20-25 times using an amicon (15kD cutoff) concentrator. Nine to ten flasks of 20 mls of media was prepared to make 8 mls of concentrated conditioned media for experiments.

Treating Cells with CM:

[0268] MCF-7 cells were seeded at 50,000 cells per well of an 8-chambered slide 1 day prior to treating with CM. Cells were seeded with complete media (MEM + 10% FBS, 1X L-glutamine). 500 µl of fresh conditioned media from Cho-Lox12 cells was added to the chambers containing MCF7 cells. The cells were incubated with the CM for 48 hours. Conditioned media from MCF7 wildtype cells was used as a negative control. After 48 hour incubation with CM, the cells were stained with rhodamine phalloidin (FIGURE 8).

Example 5: Anti-LOXL2 mAb Blocking Assays with cells treated with Conditioned Media (CM)

[0269] MDA-MB-231 (FIGURES 9, 10, 12) or Hs578t cells (FIGURE 11) were seeded in a T75 flask at 80% confluency and cultured in DMEM, 10% FBS, and 1X L-glutamine. These cells were grown for 72 hours to acquire the CM used for experiments. After 72 hours the CM was briefly centrifuged to eliminate dead cells and debris and was placed onto MCF-7 cells (FIGURES 10, 11) or SW620 cells (FIGURE 12) that were previously seeded at 50,000 cells per well in an 8-chambered slide. EMT-like phenotype changes were typically seen after 48 hour incubation with the conditioned media. MCF-7 or SW620 CM was used as a negative control. Two separate experiments were performed to demonstrate the blocking ability of anti-loxl2 mAbs to inhibit the phenotypic changes that occur with epithelial-mesenchymal transition (EMT).

Experiment 1: “Pre-incubation “:

[0270] One ml of CM (centrifuged to eliminate cellular debris) from MDA-MB-231 or Hs578t cells was pre-incubated with 2 µg or 4 µg (final concentration) of anti-loxl2 for 1 hour and 30 minutes prior to adding to MCF7 or SW620 cells. Anti-actin was used as a negative mAb control. (FIGURE 10E) The conditioned media was then added to the MCF7 or SW620 cells and incubated in 37°C and 5% CO2 for 48 hours. The actin cytoskeleton of the MCF7 or SW620 cells were stained with rhodamine phalloidin to analyze the blocking of EMT phenotypic changes (FIGURE 9).

Experiment 2: “Not preincubated “:

[0271] MDA-MB-231 or Hs578t cells were seeded into a T25 flask at 80% confluency and cultured in DMEM, 10% FBS, and 1X L-glutamine. Anti-Loxl2 mAbs (4 µg final concentration) were added to each flask respectively and the flasks were incubated with the media for 72 hours. Anti-actin was used as a negative mAb control (FIGURE 10E). The conditioned media was centrifuged to eliminate any cellular debris and then added to the MCF7 or SW620 cells and incubated in 37°C and 5% CO2 for 48 hours. The actin cytoskeleton of the MCF7 or SW620 cells were stained with rhodamine phalloidin to analyze the blocking of EMT phenotypic changes (FIGURES 11, 12).

Example 6: Anti-LOXL2 mAb Blocking Assays with cells treated with CM from transfected cells

Generation of hLOXL-2 MCD Stable Cell Line

[0272] pSecTag2hygro-hLOXL2 MCD (Minimal Catalytic domain, amino acids TAPDLVLNAE...to end of reading frame+Myc+His tags) was transfected into Hek293 cells and individual clones selected under Hygromycin B selection. Expression was gauged via Western blot with an anti-His antibody (see FIGURE 22)

Generation of Conditioned Media for EMT Studies in SW620 Cells

[0273] hLOXL2 MCD Hek293 stable cell line #7 was plated into a T175 flask using 12E6 cells or 6E6 cells, both in
30ml of cDMEM (DMEM + L-glutamine + 10% FBS, no Penn/Strep). The cells were grown for 72 hours and then the conditioned media was harvested for use in the SW620/EMT experiment described below. As a control, Hek293 cells were plated out at the same densities and treated in the same respect.

Conditioned Media from stable Lox12-MCD and induction of EMT:

[0274] SW620 cells were seeded at 50,000 cells per well in an 8-chambered well slide with DMEM, 10% FBS, and 1X L-glutamine. The conditioned media from cells expressing human Lox12-MCD was harvested for use in the SW620 / EMT assay as described above. In each chamber, 500 μl of conditioned media was added to the respective wells. Conditioned media from 293 cells was used as a negative control. EMT-like phenotype changes were typically seen after 72-96 hours later. (FIGURE 13)

[0275] CM from stable clones expressing human Lox12-SRCR domains 1-2 and 3-4 did not induce EMT-like phenotype changes after 72-96 hours.

Example 7: Assay for LOX/LOXL inhibitors with chemotherapeutic agents

[0276] LOX/LOXL inhibitors identified in Examples 2, 3, or 4 that reduce EMT/promote MET are used to treat BT-549, Hs578St, MBA-MD231, or NCI-H226 tumor cell lines, or alternatively, cell lines such as MCF-7 or SW620 that have been transfected to express LOX/LOXL or treated with CM from cells expressing LOX/LOXL.

[0277] Chemotherapeutic agents such as, alkylating agents (e.g. cisplatin, carboplatin), antimetabolites (e.g. methotrexate, gemcitabine), anthracyclines (e.g. doxorubicin); topoisomerase inhibitors (e.g. etoposide), mitotic inhibitors (e.g. paclitaxel), EGFR inhibitors (e.g. erlotinib or gefitinib), or other agents, such as, docitaxel, anthracycline, 5-fluorouracil, are added to the cells concomitantly with, or after, treatment with the LOX/LOXL inhibitor.

[0278] Cells treated with LOX/LOXL inhibitors and a chemotherapeutic agent are compared to cells treated with a chemotherapeutic agent alone using cell viability and apoptosis assays. Cell viability is measured using CellTiter-Glo™ (Promega) and apoptosis is measured using Apo-ONE™ (Promega), protocols as described in the manufacturer's manual.

[0279] A dose response curve for each set of experimental conditions (range of chemotherapeutic doses, LOX/LOXL inhibitor dose, number of doses, time of treatment) using triplicates, is plotted. Invasion and migration assays are also used for analysis, to determine if any synergy is observed between a LOX/LOXL inhibitor and chemotherapeutic drug in reducing cell invasion and migration.

[0280] LOX/LOXL inhibitors that act in synergy with a chemotherapeutic agent should have decrease in cell viability, increase in number of apoptotic cells, and/or decrease in invasion or migratory ability in comparison to cells treated with the chemotherapeutic agent alone.

[0281] Those LOX/LOXL inhibitors that act in synergy with a chemotherapeutic agent are selected as candidates for further development.

Example 8: Drug Sensitivity Assays with LOX/LOXL Inhibition

[0282] 96 well plates were seeded with 7,500 cells per well and 24 hrs later the medium was replaced with medium containing various concentrations of Cisplatin (Calbiochem, Gibbstown, NJ), Erlotinib (LC Laboratories, Woburn, MA), Paclitaxel (MP Biomedicals, Solon, OH), Methotrexate (Calbiochem, Gibbstown, NJ), B-amino-p-proionitrile (Sigma-Aldrich, St. Louis, MO) or 250ng/well antibody. After 5 days of continuous exposure, cultures were rinsed and live cell number was determined using CellTiter Glo™ (Promega, San Luis Obispo, CA) according to manufacturer instructions. Each drug concentration had 3 samples per cell line. (FIGURES 36,37,38)

[0283] For siRNA drug sensitivity studies, cells were transiently transfected with 20uM LOX, LOXL2, or non-targeting Stealth Select™ RNAi validated oligos using the Dharmafect transfection reagent according to manufacturer instructions (Thermo Scientific, Lafayette, CO) 24 hrs prior to drug exposure. Knock down levels following drug exposure were verified with quantitative PCR. Stable shRNA cell lines were generated using the MISSION® shRNA Lentiviral System (Sigma-Aldrich, St. Louis, MO). Knock down of LOX or LOXL2 was verified with quantitative PCR (FIGURE 35).

Example 9: Antibodies to LOX and LOXL2

[0284] Antibodies recognizing LOX and LOXL2 proteins are generated by immunizing mice with the peptides listed in Table 1. SEQ ID 1 and 8 are used to generate antibodies. The antibodies generated are screened to determine whether the antibodies specifically recognize the uncleaved, non-active form of LOX, the mature, active form, or both the uncleaved and cleaved forms.

[0285] Peptides of SEQ ID 2-6 are based on the mature LOX or LOXL2 enzyme. A peptide selected from Table 1 is
used to immunize mice. BALB/c mice are injected with 160 mg of purified peptide. For the initial injection, the peptide is mixed with Freund’s complete adjuvant (1:1) and injected subcutaneously. Subsequent injections are intraperitoneally in the absence of adjuvant.

[0286] Serum antibody to LOX or LOXL2 is determined by an enzyme linked immunosorbent assay (ELISA) in which the full-length or active LOX or LOXL2 protein is bound to polystyrene plates. After at least 2 immunizations over a period of at least 2 months, the spleen of one mouse with a high titer antibody directed against LOX or LOXL2 is removed and fused with cells of the P3 U1 mouse plasmacytoma cell line. The resulting clones are screened for their ability to bind LOX or LOXL2, or both, using the full-length as well as the active forms, in ELISA assays.

[0287] The specificity of the antibody to LOX or LOXL2, individually or cross-reactive, is determined by ELISA. A hybridoma-producing antibody reactive with LOX or LOXL2 is isolated and subcloned. This hybridoma is grown in tissue culture media as well as in ascites to serve as a source of LOX or LOXL2 antibody.

[0288] For generating human monoclonal antibody to LOX or LOXL2, as described in EP 0239400 (Winter et al.), the above-described mouse monoclonal is altered by substitution of its complementarity determining regions (CDRs) into a human monoclonal antibody or monoclonal antibody fragment. The CDRs from human heavy and light chain Ig variable region domains are substituted with alternative CDRs from murine variable region domains. These altered Ig variable regions may subsequently be combined with human Ig constant regions to create antibodies, which are totally human in composition except for the substituted murine CDRs. Such CDR-substituted antibodies would be predicted to be less likely to elicit an immune response in humans compared to chimeric antibodies because the CDR-substituted antibodies contain considerably less non-human components. The process for humanizing monoclonal antibodies via CDR “grafting” has been termed "reshaping." (Riechmann et al., Nature 332: 323-327 (1988); Verhoeyen et al., Science 239: 1534-1536 (1988)).

[0289] Transplantation of the murine LOX or LOXL2 antibody CDRs (such as CDRs from the murine monoclonal antibodies as described in Burbelo et al. Coll. Relat. Res. 6:153-162 (1986)) is achieved by genetic engineering whereby CDR DNA sequences are determined by cloning of murine heavy and light chain variable (V) region gene segments, and are then transferred to corresponding human V regions by site directed mutagenesis. In the final stage of the process, human constant region gene segments of the desired isotype (usually gamma I for CH and kappa for CL) are added and the humanized heavy and light chain genes are co-expressed in mammalian cells to produce soluble humanized antibody.

[0290] The transfer of these CDRs to a human antibody confers on this antibody the antigen binding properties of the original murine antibody. The six CDRs in the murine antibody are mounted structurally on a V region "framework" region. The reason that CDR-grafting is successful is that framework regions between mouse and human antibodies may have very similar 3-D structures with similar points of attachment for CDRs, such that CDRs can be interchanged. Such humanized antibody homologs may be prepared, as exemplified in Jones et al., Nature 321: 522-525 (1986); Riechmann et al., Nature 332:323-327 (1988); Queen et al., Proc. Nat. Acad. Sci. USA 86:10029 (1989); and Orlandi et al., Proc. Natl. Acad. Sci. USA 86:3833 (1989).

[0291] Nonetheless, certain amino acids within framework regions are thought to interact with CDRs and to influence overall antigen binding affinity. The direct transfer of CDRs from a murine antibody to produce a humanized antibody without any modifications of the human V region frameworks often results in a partial or complete loss of binding affinity. Thus it may be desired to alter residues in the framework regions of the acceptor antibody in order to obtain binding activity.

[0292] Queen et al., Proc. Nat. Acad. Sci. USA 86: 10029-10033 (1989) and WO 90/07861 (Protein Design Labs Inc.) have described the preparation of a humanized antibody that contains modified residues in the framework regions of the acceptor antibody by combining the CDRs of a murine mAb (anti-Tac) with human immunoglobulin framework and constant regions. They have demonstrated one solution to the problem of the loss of binding affinity that often results from direct CDR transfer without any modifications of the human V region framework residues; their solution involves two key steps. First, the human V framework regions are chosen by computer analysis for optimal protein sequence homology to the V region framework of the original murine antibody, in this case, the anti-Tac MAb. In the second step, the tertiary structure of the murine V region is modeled by computer in order to visualize framework amino acid residues, which are likely to interact with the murine CDRs and these murine amino acid residues are then superimposed on the homologous human framework. Their approach of employing homologous human frameworks with putative murine contact residues resulted in humanized antibodies with similar binding affinities to the original murine antibody with respect to antibodies specific for the interleukin 2 receptor (Queen et al., 1989 [supra]) and also for antibodies specific for herpes simplex virus (HSV) (Co et al., Proc. Nat. Acad. Sci. USA 88: 2869-2873, (1991)).

[0293] Further details of this humanization procedure are given in U.S. 5,225,539 to Winter et al., U.S. 4,816,397 to Boss et al and U.S. 4,816,567 and U.S. 6,331,415 to Cabilly et al., all of which are known to those in the art and are specifically incorporated by reference for purposes of describing the exemplified preparation.

[0294] Antibodies recognizing both LOX and LOXL2 are generated by immunizing mice as described above, with peptides having randomized amino acids of non-conserved amino acids between LOX and LOXL2, for example, between SEQ ID 4 and 5, and between SEQ ID 6 and 7. The antibodies generated should be cross-selective for LOX and LOXL2.
Those LOX/LOXL2 antibodies that are specific for LOX or LOXL2, or cross-reactive to both LOX and LOXL2, are selected as candidates for further development.

Example 10: Generation of antibodies cross-reactive to LOX and LOXL members

Antibodies cross-reactive to LOX and LOXL members are generated by immunizing mice with peptides derived from the highly conserved C-terminal region of the LOX/LOXL proteins, which also encompasses the catalytic domain. Antibodies generated against this region recognize the active form of LOX/LOXL.

Domains from which peptides to generate antibodies may be derived from are the catalytic domain, copper-binding domain, lysyl-tyrosylquinone co-factor domain, and cytokine receptor-like domain. Sequences of the copper-binding domain and catalytic domain are listed in Table 2 and are used to immunize mice as described in Example 9. Similarly, the specificity of the antibody generated is determined by ELISA against the full-length and processed forms of LOX, LOXL, LOXL2, LOXL3, and LOXL4.

Peptides with randomized amino acids of non-conserved amino acids between LOX, LOXL, LOXL2, LOXL3, and LOXL4 are also used to immunize mice to generate antibodies that are cross-reactive with the various forms of LOX/LOXL protein, for example LOX and LOXL, or for all 5 LOX family members. Immunization of mice and generation of mouse and human antibodies is described in Example 9.

The LOX/LOXL antibodies that are cross-reactive for LOX and various LOXL members are selected as candidates for further development.

Example 11: Generation of antibodies recognizing active LOX/LOXL that reduce EMT/promotes MET

[0300] EMT cells secrete active LOX/LOXL. Antibodies generated from Examples 9 and 10 are used in treating EMT cells in Examples 2, 3 or 4. The EMT or MET characteristics of the cells are then determined as described in Example 1. Antibodies that recognize the active LOX/LOXL2 should reduce EMT and promote MET of the cells.

[0301] Those LOX/LOXL antibodies that reduce EMT and promote MET of the cells are selected as candidates for further development.

Example 12: Inhibition of LOX/LOXL activity by antibodies

[0302] Antibodies generated from Examples 9 or 10 are used in LOX/LOXL activity assays as described in Fogelgren et al., J. Biol. Chem. 280:24690-24697 (2005). Briefly, the LOX/LOXL activity assay reaction mixture consists of 50mM sodium borate (pH 8.2), 1.2M urea, 40uM Amplex Red, 0.1 units/ml horseradish peroxidase, and 10mM 1,5-diamineopentane (cadaverine) substrate. Alternatively, the Amplex Red assay is performed in a physiological buffer such as phosphate buffer at pH 7.5. The protein, LOX/LOXL, is added to the reaction mixture in the presence or absence of 500uM BAPN or antibodies from Examples 9 or 10, and incubated. The fluorescent product is excited at 560nm, and emission is read at 590 nm (e.g. BMG Labtechnologies Inc. Polarstar Optima). LOX/LOXL in the presence of BAPN serves as a negative control, whereas absence of BAPN serves as a positive control. The measure of activity is based on the amount of fluorescence.

[0303] Those LOX/LOXL antibodies that inhibit LOX/LOXL activity are selected as candidates for further development.

Example 13: Inhibition of LOX/LOXL binding to other cellular or extracellular matrix components by LOX/LOXL antibodies

[0304] Antibodies generated from Examples 9 or 10 are used in ECM binding assays. Solid phase binding assays are performed as described in Fogelgren et al., J. Biol. Chem. 280:24690-24697 (2005). Wells of high protein-binding EIA/RIA microplate (Coming) are coated with tropoelastin, Type I collagen, soluble plasma fibronectin (pFN), insoluble cellular fibronectin (cFN), laminin, or BSA overnight at 4°C. The wells are blocked, washed, and then incubated overnight with a tagged version of LOX/LOXL (e.g. GST-LOX/LOXL) with or without the LOX/LOXL antibodies. The wells are again washed and the amount of LOX/LOXL binding is detected by a primary antibody against the tag of the LOX/LOXL (e.g. anti-GST), followed by a peroxidase-labeled secondary antibody. The peroxidase activity is then quantitated with a fluorogenic peroxidase substrate kit (Pierce). The samples are performed in triplicate and dissociation constants calculated with statistical software (e.g. Prism3 from Graphpad, Inc.).

[0305] Binding assays are also performed in which LOX/LOXL is used to coat the microplate wells. Antibodies from Examples 9 or 10 are added to the wells, prior to, or concurrent with tropoelastin, Type I collagen, pFN, cFN, or BSA. Binding is measured as described above, where the ECM proteins are detected with their respective antibodies, or an antibody against the tag, if a tagged form of the ECM protein is used, to detect the amount of ECM bound.

[0306] Binding of LOX/LOXL with other proteins, such as cellular receptors (e.g. uptake receptor integrin beta1), BTK (burton agammaglobulinemia tyrosine kinase), or other integrins is also performed using the aforementioned assay, wherein instead of ECM proteins are used, cellular receptors (e.g. uptake receptor integrin beta1), BTK (burton agammaglobulinemia tyrosine kinase) or other integrins are used.

[0307] Those LOX/LOXL antibodies that inhibit LOX/LOXL binding to ECM proteins, cellular receptors, and integrins, are selected as candidates for further development.

Example 14: Inhibition of LOX activity

[0308] Specific LOX activity was evident on the cell surface of NIH3T3 cells. Activity was quantitated with a horseradish peroxidase-coupled fluorescent assay method based on the oxidation of Amplex Ultra Red with a 1,5-diaminopentane substrate. LOX activity was inhibited with the irreversible small molecule inhibitor, BAPN, with a monoclonal antibody raised against a LOX peptide, and with a siRNA oligonucleotide specifically targeting LOX mRNA. (FIGURE 15)

[0309] NIH 3T3 cells were transfected with 100nM of LOX siRNA (Invitrogen Stealth, HSS106117, AUAACAGCCGACUCAAUCCCGU) or non-targeting control. 25ul of Dharmafect® #3 (Dharmacon) was mixed with 1ml of OPTIMEM

I® (Invitrogen) and sat for 5 minutes at room temperature. 50ul of 20uM siRNA was then added, mixed, and the transfection mix was incubated at room temperature for 15 minutes. 1ml of transfection mix was then added to a trypsinized cell suspension in growth media containing 1x10^6 cells and the resulting mixture was plated into a 10cm^2 culture dish. Six days after transfection, cells were trypsinized and replated into 96 well plate format at 50,000 cells/well. Day seven after transfection, cells were washed 2x with PBS and incubated with 100ul of the following reaction mix: 100uM Amplex Ultra Red® (Invitrogen), 20mM diaminopentane (Fluka), and 4u/ml horseradish peroxidase (Sigma) in PBS. BAPN and LOX mAb were added to 1mM and 15ug/ml final concentrations, respectively, immediately before diaminopentane and HRP addition. The plate was read in a Molecular Devices M5 plate reader at 37°C. The plate reader was configured to read fluorescence (ex=544 nm, em=590 nm) in kinetics mode for approximately 2.5 hours.

Example 15: Inhibition of LOXL2 activity

[0310] All plates were obtained from Corning. Secondary antibody and Pico substrate were from Pierce. Amplex red reagent was from Invitrogen. Horse radish peroxidase (HRP), 1,5-diaminopentane, antifoam were from Sigma. All ProteOn reagents were from Bio-Rad. LOXL2 was from R&D systems. Antibodies used in this study were produced at Antibody Solution or via ascites from Aragen Biosciences. All other reagents were of the highest quality possible.

Binding via ELISA

[0311] Binding of antibody to LOXL2 was determined using a luminescence based ELISA. White Corning plates were coated with 0.1 µg/mL of LOXL2 or antigen of interest in 50 mM borate buffer (pH 8.0) overnight at 4°C. Plates were washed using BioTek plate washer and blocked with 5% skim milk in PBST (0.05% tween-20) for 1 hour at room temperature. Plates were washed with PBST (0.05% tween-20) and then used immediately or stored at 4°C in dessicator for future use. The antibody to be tested was serially diluted in PBST (0.01% tween-20) and 100 µL of each dilution was added per well. Plates were incubated with test article for 1 hour at room temperature and then washed with PBST (0.05% tween-20). Detection antibody (anti-mouse HRP conjugate) was diluted 16000 fold in 5% skim milk in PBST (0.05% tween-20) and 100 µL was applied per well. Plates were incubated for 1 hour with detection antibody and then washed with PBST (0.05% PBST). Signal was detected using the SuperSignal ELISA pico chemiluminescent substrate from Pierce following the manufacturer’s instructions. Luminescence was measured using a Molecular Devices M5 plate reader with an integration time of 500 ms capturing all wavelengths. Data was background corrected and the dependence of luminescence signal to antibody concentration was fit using the Langmuir isotherm equation using the GraFit program. In instances where the antigen concentration was similar to the dissociation constant the quadratic equation of tight binding was used. Reported dissociation values were obtained from the fits to these equations.

[0312] Langmuir Isotherm equation

$$[PL] = \frac{B_{\text{max}} \cdot [L]}{K_D \cdot [L]}$$

[0313] Tight binding equation

$$[PL] = B_{\text{max}} \cdot \frac{(E)_T + [S]_T + K_D - \sqrt{(E)_T + [S]_T + K_D}^2 - 4(E)_T[S]_T}{2(E)_T}$$

Binding via SPR (Surface Plasmon Resonance)

[0314] Binding affinities were measured using a Bio-Rad ProteOn instrument thermostated to 25 °C. The binding affinities were determined using two methods, using amine coupling; one in which the antibody was immobilized and the antigen (LOXL2) was added, and another in which the antigen (LOXL2) was immobilized and antibody was added. Antibody or antigen was immobilized on a GLC chip using at 1:1 ratio of NHS to EDC provided with the ProteOn immobilization kit. Chip was first activated with NHS/EDC a mixture and then antigen or antibody at 1 µg/mL in acetate buffer pH 4.5 was flowed over activated surface to couple. This typically yielded a coupling of about 500 RU’s. The activated chip surface was then capped with the addition of 1M ethanolamine. Coupled chips were stored at 4°C and regenerated with 50 mM sodium hydroxide.

[0315] Dissociation constants were determined by probing the coupled chip with a dilution series of antibody or antigen in PBST (0.05% tween-20). Data was acquired on all six channels available on the ProteOn using a non-coupled channel
as a reference. Collected data was analyzed using ProteOn manager software from Bio-Rad.

**Screening assays**

[0316] Antibody candidates were initially chosen based on ELISA point tests. ELISA on multiple antigens was performed by Antibody Solutions and antibodies showing strong ELISA signal in the antigen of interest were selected for further characterization in enzymatic assays. LOXL2 produces hydrogen peroxide when the substrate 1,5-diaminopentane is deaminated and the enzyme regenerated.

[0317] Antibodies were assessed for their ability to inhibit enzymatic activity using a biochemical assay that couples the production of peroxide (liberated by LOXL2) to HRP and measuring the conversion of amplex red to a fluorescent product. Antibody hybridoma supernatant (10 μL) was added to 40 μL enzyme mixture (50 mM sodium borate pH 8.0, 5 units/mL HRP, 125 nM LOXL2, 10 ppm antifoam) and incubated at room temperature for 1 hour in a 96 well full area black plate. Enzymatic reaction was started with the addition of 50 μL of substrate solution (62.5 mM sodium borate, 100 μM amplex red reagent, 20 mM 1,5-diaminopentane, 10 ppm antifoam) and read in a Molecular Devices M5 plate reader at 37°C. The plate reader was configured to read fluorescence (ex=544 nm, em=590 nm) in kinetics mode for 1 hour. Data was recorded as the slope of the fluorescence response to time. These slopes were compared to a control in which hybridoma media was added to the enzyme mixture. Slopes less than that of control were considered inhibitors.

**IC50 determinations**

[0318] Dose responses on selected antibodies were carried out against LOXL2 using the coupled enzymatic assay described above. A dilution series of antibody was created in PBST (0.01% tween-20) and 10 μL of this was added to 40 μL of enzyme mixture (50 mM sodium borate pH 8.0, 5 units/mL HRP, 125 nM LOXL2, 10 ppm antifoam) and incubated at room temperature for 1 hour in a 96 well full area black plate. Enzymatic reaction was started with the addition of 50 μL of substrate solution (62.5 mM sodium borate, 100 μM amplex red reagent, 20 mM 1,5-diaminopentane, 10 ppm antifoam) and read in an M5 plate reader using conditions described above. The slopes of the fluorescence response as a function of time were plotted against antibody concentration and the data was fit to a four parameter fit using GraFit. The midpoint of this plot is the apparent IC50 and is the concentration at which fifty percent of the total response is inhibited (for example, **FIGURE 20**).

**Mode of inhibition**

[0319] Mode of inhibition of antibodies against LOXL2 was conducted using the model described below. In these experiments, the dependence of the steady state rate on the concentration of 1,5-diaminopentane was monitored under increasing concentrations of antibody. The purpose was to assess whether the K_m for substrate, k_cat or both change in the presence of antibody. Collected data was analyzed globally with GraFit using the model shown in figure below. Parameter α describes the effect of the compound on substrate affinity. An α value equal to one describes a situation in which the compound binds equally well the free enzyme and the enzyme-substrate complex (non-competitive inhibition like). Values less than one describe an interaction in which the compound binds the free enzyme better than the enzyme-substrate complex (competitive inhibition like). Values greater than one correspond to the compound binding the enzyme-substrate complex (un-competitive inhibition like). Values greater than one correspond to the compound binding the free enzyme better than the enzyme-substrate complex (competitive inhibition like). The β value describes the effect of the modulator on the rate of the enzyme. Activators have values greater than one (for a complete inhibitor β=0) and inhibitors have values greater than one. K_A is the dissociation constant of the compound, K_s is the Michaelis constant for the substrate and k is the catalytic rate of the enzyme. The steady state rates were determined from the slope of the fluorescence response as a function of time as described above. Data was plotted as the dependence of steady state rate on the concentration of substrate (1,5-diaminopentane) at several fixed concentrations of antibody and analyzed with GraFit. (for example, **FIGURE 21A**, and using a direct competitor, as shown in **FIGURE 21B**).

**Example 16: Detection of LOX/LOXL by immunoblot and immunohistochemistry (IHC) analysis**

[0320] Immunoblot (western blot) analysis was performed by lysing cells in lysis buffer (for example, 100mM NaH2PO4, 10mM Tris-HCL, 8M Urea, 0.05% tween-20, pH 8.0; or EDTA, NP40, Tris, NaCl, PMSF and "Complete mini, protease inhibitor cocktail" (Roche, #11836153001); or "Laemmli’s SDS sample buffer, 4X" (Boston BioProducts, #BP-110R). The lysate (typically 15 - 25 µg total protein) was loaded onto 4-12% Tris-Glycine gels (Invitrogen Carlsbad, CA) or NuPAGE Novex 4-12% Bis Tris gels (Invitrogen). Size fractionated proteins were transferred onto PVDF membrane (Invitrogen Carlsbad, CA) or Nictrocellulose membranes (Invitrogen).

[0321] ImmunobLOTS were blocked overnight at 4°C in 2% BSA, 5% dry milk in PBS. Following incubation with anti-LOX/LOXL primary antibody (monoclonal or polyclonal), blots were incubated with secondary antibodies to enable
The following day, the matrix and collagen approximately 48-72 hours later. Confluency, cells were seeded at 100,000 cells per slide. High confluency was used for detection of Lox associated with seeded at 30-40,000 cells per slide. Low confluency was used for detection of Lox in the cytosol 24 hours later. For high chamber glass slide (BD Falcon, Franklin Lakes, NJ) and allowed to adhere overnight. For low confluency, cells were Hs578t cells were cultured in DMEM containing 10% FBS and 1x glutamine. The cells were seeded in an 8 chamber glass slide (BD Falcon, Franklin Lakes, NJ) was incubated one hour prior to fixing the cells with 4% PFA. Secondary Ab for collagen was donkey anti-collagen antibody (1:50, Calbiochem anti-collagen type I Rabbit polyclonal, Gibbstown, NJ) was incubated one hour prior to fixing the cells with 4% PFA. Secondary Ab for collagen was donkey anti-rabbit Cy3 (ImmunoJacksonLabs, West Grove, Pa).

**Example 17: Detection of 2 forms of LOXL2**

**Example 18: Internalization and Uptake of LOX/LOXL2**

**Example 19: Detection of 2 forms of LOXL2**

**Example 20: Internalization and Uptake of LOX/LOXL2**

**siRNA knockdown of Lox and Loxl2 in Hs578t cells:**

Hs578t cells were cultured in DMEM containing 10% FBS and 1x glutamine in 10 cm tissue culture plates. The cells were permeabilized by adding saponin buffer (0.5% Saponin/1% BSA in PBS) at room temperature for 20 minutes. The secondary detection Ab (Alexa Fluor 488 donkey anti-mouse IgG, Invitrogen, Carlsbad, Ca.) was added at room temperature in saponin buffer and the cells were incubated for 30-45 minutes. The cells were then washed 3X in saponin buffer. The slides were mounted with vectashield (Vector Laboratories, Burlingame, Ca).

To detect collagen detection, anti-collagen antibody (1:50, Calbiochem anti-collagen type I Rabbit polyclonal, Gibbstown, NJ) was incubated one hour prior to fixing the cells with 4% PFA. Secondary Ab for collagen was donkey anti-rabbit Cy3 (ImmunoJacksonLabs, West Grove, Pa).

**siRNA knockdown of Lox and Loxl2 in Hs578t cells:**

Hs578t cells were cultured in DMEM containing 10% FBS and 1x glutamine in 10 cm tissue culture plates. The cells were grown until they were approximately 75% confluent. Two mixtures were made: In one 15 ml conical tube, 60 µl of 20µM of siRNA was mixed with 1 ml of OptiMEM™ (Thermo Scientific, Chicago, Illinois) transfection reagent was mixed with 1 ml of OptiMEM™. The two tubes were
incubated at room temperature for 5 minutes. After 5 minutes, the contents of both tubes were mixed into one. The mix was carefully pipetted up and down and incubated for 20 minutes at room temperature.

[0331] Hs578t cells were trypsinized and resuspended in 10 mls of complete media and were added to a 10cm tissue culture plate. For each siRNA condition, 2mls of the combined transfection mixture was added to the 10cm plate. The plates were gently swirled and were placed in the incubator with 37C and 5% CO2 overnight. The media did not need to be changed and was left on the cells for many days. For immunofluorescent studies (FIGURES 23, 24, 35), the transfection proceeded for at least 5 days to ensure sufficient knockdown and lowered protein levels.

**Summary**

[0332] The results demonstrate that at low cell confluency, LOX and LOXL2 do not remain secreted in the extracellular matrix but instead can be re-uptaken by tumor cells (as the antibody is internalized). The specificity of these staining patterns (FIGURES 23, 24, 25) was supported by matched siRNA knockdown controls. At high cell confluency, LOX and LOXL2 are now detected readily outside the cell in the extracellular matrix, with apparently little re-uptake. Staining patterns were supported by matched siRNA knockdown controls. Similar results of internalization and uptake of anti-Lox and anti-Loxl2mAbs and their colocalization with collagen was obtained for Loxl2 mAbs treatment of cells in place of siRNA knockdown.

**Example 19: Time Course of LOX/LOXL2 Internalization and Uptake**

[0333] The time course was initiated on cells that were already confluent (day 0). The cell line used was breast tumor cell line Hs578t, which expresses both LOX and LOXL2.

**IHC protocol (cells on chamber slides; based on DAKO’s En Vision+ System-HRP):**

[0334] All the steps were done at RT (room temperature), the primary antibody concentration was 5 μg/ml for anti-LOX and 15ug/ml for anti-LOXL2. The cells were washed with PBS (x 3). Then a peroxidase block (5 min) was performed before washing again with with PBS (x 3). The cells were then incubated with primary antibody diluted in 0.05 M Tris-HCl, pH 7.6 w/ 1% BSA (30 min). M64 and M20, LOX and LOXL2 monoclonal antibodies, respectively, (see for example FIGURE 26) were used. The cells were then washed with PBS (x 3) before being fixed with 4% PFA (10 min). the cells were then washed again with PBS (x 3) before being fixed with Peroxidase Labelled Polymer (30 min). The cells were then washed with PBS (x 3). The Substrate-Chromogen (20 μL DAB per 1 mL Substrate Buffer) was then added for 5-10 min. The cells were then washed with distilled water before counterstaining with hematoxylin (optional at times), dehydrated and permanently mounted with Entellan.

**Picro-Sirius Red (Sirius Red F3B) staining protocol:**

[0335] Sirius Red staining was used for collagen histochemistry. The cells were fixed with 4% PFA (10 min), however, the fixation is not critical. The cells were then stained in Picro-Sirius Red (Sirius Red 0.1% in saturated picric acid (Electron Microscopy sciences, cat# 26357-02) for 1 hour at RT. The cells were then washed in 2 changes of acidified water (5 mL acetic acid in 1 L of distilled water) before being dehydrated in graded series of ethanol and mounted.

**Results**

[0336] As shown in FIGURE 27, at Day 0, LOX and collagen I were already secreted and associated with the matrix, but LOXL2 was localized in the cytosol and was not secreted nor associated with the matrix yet. At Day5, more LOX and collagen I was secreted, and LOXL2 was secreted/associated with the matrix. At Day 9, LOX, LOXL2, collagen I and Sirius red all showed similar staining patterns, indicating LOX, LOXL2 and collagen I co-localize in the same regions. At Day11, a change in LOX staining pattern was detected, indicating less LOX was being secreted and/or associated with the matrix. LOX2, collagen I and Sirius Red staining, however, were still similar to each other and no real change in staining patterns was detected. Staining patterns of all the proteins at Day 13 and Day 15 were similar to those of Day 11. Based on these results, there were some differences in the timing of the secretion of LOX and LOXL2, respectively. The secretion of LOX and LOXL2 appears to be regulated and related to cell confluency. The timing of secretion may regulate the availability of active, extracellular LOX and LOXL2, which in turn, may initiate collagen cross-linking.

[0337] This example, combined with other Examples disclosed herein, demonstrate that the secretion of LOX and LOXL2 is highly regulated. At low cell density, the data disclosed herein indicates secreted LOX and LOXL2 are rapidly re-uptaken by cells (as the specific LOX and LOXL2 antibodies are detected inside the cell, suggesting that they are efficiently internalized). At high cell density, LOX and LOXL2 are no longer re-uptaken but are found associated with the
collagen matrix (extracellular), as determined by localization of specific LOX and LOXL2 antibodies. IHC analysis of
tumor cells and liver fibrosis cells indicate that a similar regulation of LOX and LOXL2 can occur, with differential distri-
butions of intracellular and extracellular LOX/LOXL in areas of disease.

**Example 20: LOX and LOXL2 Tissue Expression**

[0338] The decloaking chamber and solutions used are from BioCareMedical (Concord, Ca) unless otherwise stated. All procedures were performed at room temperature unless otherwise stated.

[0339] The decloaking chamber was filled with 500ml of distilled water (diH20). One slide container was filled with
200mls of Universal Decloaker antigen retrieval solution and another slide container was filled with 200mls of Hot Rinse;
the tissue microarray (TMA) slides (Cybrdi, Frederick, Maryland) were placed into the container with the decloaking
solution and were then placed into the decloaking chamber. The temperature settings were set at 80°C for 30 minutes
for breast TMAs. Once the temperature reached 90°C, the slides were removed from the decloaking antigen retrieval
solution and placed into the container with hot rinse. The temperature in the hot rinse container was brought down slowly
by exchanging 1/3 of the hot rinse with 1/3 of diH20 every two minutes until the temperature within the container was at
room temperature. The slides were then rinsed once with diH20 and then once in PBS with 0.1% Tween-20.

[0340] The slides were treated with Peroxidazed-1 for 5 minutes and then rinsed one time in PBS for 2 minutes. Then,
the slides were background blocked with SNIPER for 5 to 10 minutes and then rinsed one time in PBS for 2 minutes.
Primary antibody (Ab) was diluted in Da Vinci Green Universal Diluent. 5 μg/ml of rabbit polyclonal anti-Loxl2 antibody
and 3 μg/ml of monoclonal anti-Lox M64 was used. The slides were incubated with the primary antibodies for 2 hours
and were then rinsed 3 times in PBS-Tween-20, 2 minutes each rinse. The Mach3 polymer kit was used for antigen
detection by adding mouse or rabbit probe for 20 minutes. The slides were then rinsed once with PBS-Tween-20 and
followed by the addition of mouse or rabbit polymer for 20 minutes. The slides were then rinsed 5 times in PBS-Tween-
20, 2 minutes for each wash. DAB chromagen was added to the slides for 7 minutes and rinsed once in diH20. DAB
sparkle was added to the slides for 1 minute and rinsed once in diH20. The slides were then counter stained with
hematoxylin for 30 seconds to 1 minute and were then rinsed with water for 5 minutes and followed by dehydration with
graded alcohol. The slides were mounted with entellan mounting media (Electron Microscopy Sciences, Hatfield, Pa).
Tissue expression is as shown in **FIGURES 28** and **29**.

**Example 21: LOX and LOXL2 Expression in lung adenocarcinoma**

[0341] RT-PCR analysis of LOX and LOXL2 was performed on lung adenocarcinoma. Analysis was performed on
primary tumors, but some were associated with metastasis or recurrence. The data are a ratio of tumor to a matched
adjacent “normal” piece of tissue that is not necessarily completely normal, the individual transcript data for tumor and
normal are plotted in **FIGURES 31** and **32**. LOXL2 was overexpressed in about 4-5 out of 10 tumors and tended to be
associated with tumors known to be associated with lymph node metastasis or other recurrence/metastasis (**TABLE 3**).
Primers and probes used are listed in **TABLE 4**.

Example 22: Animal Model for Diabetic Nephropathy/Kidney Fibrosis

[0342] Transgenic mice which overexpress inducible cAMP early repressor display severe diabetes and exhibit glomerular hypertrophy, glomerular basement membrane thickening and sclerotic lesions. These mice may be used as a model for diabetic nephropathy. The compounds described herein can be administered to this model system and analyzed for their ability to prevent, treat, and/or ameliorate kidney fibrosis.

[0343] Transgenic mice are raised under established protocols and guidelines for animal experiments. Treatment group size, regimens, and controls are established based on previously identified doses and administration time-points for LOX/LOXL inhibitors. Mice are monitored and/or sacrificed at pre-determined time-points throughout the experimental time-frame for histological and biochemical analyses.

[0344] Histological analyses include microscopic and immunohistochemical analyses of kidney sections. Glomerular...
surface area and glomerular number are identified via established biochemical staining and microscopic analyses. Glomerular basement membrane thickening is determined via established methods for electron microscopy of kidney sections.

[0345] Serum and urinary variables are also monitored for determination of kidney activity/failure. Blood glucose and insulin levels are determined via established methodologies including ELISA and HPLC. Serum proteins such as creatinine and albumin are also monitored via established assays. Urine samples are assayed for protein levels including albumin and creatinine. Established assays are used for the detection of proteins in urine, including ELISA and HPLC.

[0346] Utilizing an animal model system such as the diabetic nephropathy mouse model described above, the compounds disclosed herein may be tested for prevention, treatment, and/or amelioration of kidney fibroses.

Example 23: Animal Model for Myocardial Ischemia/Infarction Fibrosis and ECM Remodeling

[0347] Male Wistar rats are housed and handled per current animal handling guidelines and protocols. Treatment group size, regimens, and controls are established based on previously identified doses and administration time-points for LOX/LOXL inhibitors. Rats are subject to ischemia/reperfusion injury monitored and/or sacrificed at pre-determined time-points followed by x-ray, microCT imaging, microscopic tissue examination, and immunohistochemical analyses.

Ischemia/Reperfusion Injury Protocol

[0348] Rats are anesthetized and placed on ventilation. Hearts are surgically exposed and a mini-pneumatic coronary occluder (catheter-based occlusion system) is placed around the desired coronary artery. The chest is then closed and the occluder-catheter and venous tubing are exteriorized between the scapulae. After surgery, the animals are allowed to recover for five days prior to starting the ischemia/reperfusion protocol.

Ischemia

[0349] Ischemia is implemented via the occluder-catheter on a schedule that include at least one pre-conditioning occlusion for 20 seconds followed by 5 minutes of recovery, and at least one occlusion for 2 minutes, followed by 5 minutes of recovery. Thereafter, occlusion time can vary up to 30 minutes. Ischemic protocol lengths can vary, with a typical protocol length of 4 weeks. Ischemia is implemented once per week, and cardiac function is monitored via echocardiography throughout the protocol. Rats are euthanized at the end of the protocol, and hearts are excised and examined for microvasculature, chamber size and function, and extent of fibrosis. LOX/LOXL inhibitors are administered at predetermined time points and dosages throughout the ischemia protocol. Ascending dosages and increasing frequencies of administration are administered in groupings sufficient to establish dose-limiting toxicities and efficacies. Control animals and protocols are maintained throughout all protocols.

Analyses

[0350] Ventricle size is determined via recordation of ventricle short-axis views by echocardiography during the protocol. Diastolic and systolic areas, defined as the minimum and maximum ventricle cavity areas during cardiac phase are analyzed. Coronary flow and microvasculature of the excised hearts is determined via a variety of imaging and staining techniques including microCT and x-ray. Fibrosis of the chambers is determined via sectioning of the cardiac tissue and trichrome staining or other established staining for cardiac tissue. Cross-sectional microscopy and histological analysis is also performed for evaluation of ventricle volume, size, and ventricle wall thinning.

[0351] Utilizing an animal model system such as the cardiac ECM remodeling system described above, the compounds described herein can be tested for prevention, treatment, and/or amelioration of cardiac fibrosis and cardiac ECM remodeling.

[0352] Bleomycin induced pulmonary fibrosis is a standard model for assessment of lung fibrogenesis including IPF, Interstitial Pneumonia, and ARDS. Male Wistar rats are housed and handled as per animal handling guidelines and protocols. Treatment group size, regimens, and controls are established based on previously identified doses and administration time-points for LOX/LOXL inhibitors. Rats are intra-tracheally injected with bleomycin at established dosages (typically 5 mg/kg). Control animals are maintained throughout the treatment period.

[0353] Following administration of bleomycin, test groups are then administered the predetermined LOX/LOXL inhibitor and monitored and/or sacrificed at pre-determined time-points for assessment of lung fibroses. Test periods can vary, with an exemplary test period being 4 weeks. Following sacrifice, rat lungs are examined for fibrosis and collagen content.
Utilizing an animal model system such as the bleomycin-induced lung fibrosis animal model described above, the compounds described herein can be tested for prevention, treatment, and/or amelioration of lung fibroses.

The invention is further characterised by the following numbered clauses:

1. A method for treating or preventing tumor invasion or metastasis in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of active lysyl oxidase or lysyl oxidase-like protein.

2. A method for treating or preventing angiogenesis in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of active lysyl oxidase or lysyl oxidase-like protein.

3. A method for treating or preventing fibrosis in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of active lysyl oxidase or lysyl oxidase-like protein.

4. A method for reducing tumor growth in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of active lysyl oxidase or lysyl oxidase-like protein such that the tumor growth is reduced by at least 25%, 50%, 75%, 90%, or 95%.

5. The method of clause 1, wherein the tumor is metastatic tumor.

6. A method for increasing or enhancing the chances of survival of a subject with metastatic tumor, comprising: administering to a subject in need thereof an effective amount of an inhibitor of active lysyl oxidase or lysyl oxidase-like protein, thereby increasing or enhancing the chances of survival of the subject treated by a certain period of time.

7. The method of clause 6, wherein the survival of the subject is increased by at least 10 days, 1 month, 3 months, 6 months, 1 year, 1.5 years, 2 years, 3 years, 4 years, 5 years, 8 years, or 10 years.

8. The method of clause 1, 2, 3, 4, or 6, wherein the LOX or LOXL inhibitor is an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.

9. The method of clause 1, 2, 3, 4, or 6, wherein the LOX or LOXL inhibitor is an antibody that specifically binds to a region of LOX or LOXL having an amino acid sequence selected from SEQ ID NOs: 1-18.

10. The method of clause 1, 2, 3, 4, or 6, wherein the LOX or LOXL inhibitor is an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.

11. The method of clause 1, 2, 3, 4, or 6, wherein the LOX or LOXL inhibitor inhibits both active LOX and active LOXL2.

12. The method of clause 1, 2, 3, 4, or 6, wherein the active LOX or LOXL is a mature form of LOX or LOXL after proteolytic processing of the preproprotein.

13. A method for treating or preventing tumor invasion or metastasis in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of lysyl oxidase and an inhibitor of a lysyl oxidase-like protein.

14. A method for reducing tumor growth in a subject in vivo, comprising: administering to the subject an effective amount of an inhibitor of lysyl oxidase and an inhibitor of a lysyl oxidase-like protein such that the tumor growth is reduced by at least 25%, 50%, 75%, 90%, or 95%.

15. The method of clause 14, wherein the tumor is metastatic tumor.

16. A method for increasing or enhancing the chances of survival of a subject with metastatic tumor, comprising: administering to a subject in need thereof an effective amount of an inhibitor of lysyl oxidase and an inhibitor of a lysyl oxidase-like protein, thereby increasing or enhancing the chances of survival of the subject treated by a certain period of time.

17. The method of clause 16, wherein the survival of the subject is increased by at least 10 days, 1 month, 3 months, 6 months, 1 year, 1.5 years, 2 years, 3 years, 4 years, 5 years, 8 years, or 10 years.

18. The method of clause 13, 14, or 16, wherein the LOX or LOXL inhibitor is an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.

19. The method of clause 13, 14, or 16, wherein the LOX inhibitor and the LOXL inhibitor are different.

20. The method of clause 13, 14, or 16, wherein the LOX inhibitor and the LOXL inhibitor are different and specifically bind to the LOX and the LOXL, respectively.

21. The method of clause 13, 14, or 16, wherein the LOX inhibitor or the LOXL inhibitor is an antibody that specifically binds to a region of the LOX or the LOXL having an amino acid sequence selected from SEQ ID NOs: 1-18.

22. The method of clause 13, 14, or 16, wherein the LOX inhibitor and the LOXL inhibitor is a single antibody, wherein the antibody has binding affinity for both the LOX and the LOXL.

23. The method of clause 13, 14, or 16, wherein the LOXL inhibitor is an inhibitor of LOXL1, LOXL2, or LOXL4.

24. The method of clause 13, 14, or 16, wherein the LOX inhibitor is an inhibitor of LOXL2 or LOXL4.

25. The method of clause 13, 14, or 16, wherein the LOX or LOXL inhibitor is an inhibitor of active LOX, LOXL2 or LOXL4.

26. The method of clause 13, 14, or 16, wherein the LOX or LOXL inhibitor inhibits both active LOX and active LOXL2.

27. A composition comprising: an inhibitor of lysyl oxidase, an inhibitor of a lysyl oxidase-like protein, and a phar-
maceutically acceptable carrier.

28. A method for treating a host with a disease associated with abnormal cell proliferation, abnormal angiogenesis, abnormal cell invasion or migration in local tissues and/or at distant sites, or a fibrotic disease, comprising: administering to the host a therapeutically effective amount of an inhibitor of at least one lysyl oxidase or lysyl oxidase-like protein in combination with a second therapeutic agent that is not the LOX or LOXL inhibitor.

29. The method of clause 27, wherein the LOX or LOXL inhibitor is an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.

30. The method of clause 27, wherein the LOX or LOXL inhibitor is an antibody that specifically binds to a region of LOX or LOXL having an amino acid sequence selected from the group consisting of SEQ ID Nos: 1-18.

31. The method of clause 27, wherein the LOX or LOXL inhibitor is an inhibitor of active LOX, LOXL2 or LOXL4.

32. The method of clause 27, wherein the LOX or LOXL inhibitor inhibits both active LOX and active LOXL2.

33. The method of clause 30, wherein the active LOX or LOXL is a mature form of LOX or LOXL after proteolytic processing of the preproprotein.

34. The method of clause 27, wherein the second therapeutic agent is a chemotherapeutic agent.

35. The method of clause 27, wherein the second therapeutic agent is a therapeutic biologic.

36. The method of clause 27, wherein the second therapeutic agent is radiation.

37. The method of clause 27, wherein the LOX or LOXL inhibitor and the second therapeutic agent treat the disease synergistically through inhibition of LOX or LOXL which renders the diseased cells in the host more susceptible to the anti-proliferative or pro-apoptotic effects of the therapeutic agent and reduces the viability of the diseased cells.

38. The method of clause 27, wherein the disease associated with abnormal cell proliferation is cancer, tumors, or restenosis.

39. The method of clause 27, wherein the fibrotic disease is selected from dermal scar formation, keloids, liver fibrosis, lung fibrosis, kidney fibrosis, diabetic nephropathy, scleroderma, and glomerulosclerosis.

40. A composition comprising: an inhibitor of at least one lysyl oxidase or a lysyl oxidase-like protein, a second therapeutic agent that is not the at least one lysyl oxidase or a lysyl oxidase-like protein, and a pharmaceutically acceptable carrier.

41. A method for selecting an inhibitor of tumor invasion, angiogenesis or metastasis, comprising: contacting cells that are in an epithelial-mesenchymal transition (EMT) state with an inhibitor of lysyl oxidase or a lysyl oxidase-like protein; and detecting a change in the EMT state of the cells, wherein reduction of the EMT state or a shift from the EMT to a mesenchymal-epithelial transition (MET) indicates that the LOX or LOXL inhibitor is an inhibitor of tumor invasion, angiogenesis or metastasis.

42. The method of clause 41, wherein the EMT state of cells has a characteristic selected from positive vimentin, positive fibronectin staining, low or non-detectable levels of E-cadherin staining, an elongated and remodeled actin cytoskeleton as revealed by phalloidin staining of F-actin.

43. The method of clause 41, wherein the MET state of cells has a characteristic selected from low or non-detectable levels of vimentin, low or non-detectable levels of fibronectin staining, positive or high levels of E-cadherin staining, physiologically normal actin cytoskeleton as revealed by phalloidin staining of F-actin.

44. The method of clause 41, wherein the reduction of the EMT state or a shift from the EMT to a MET state is detected by measuring or detecting a decrease in vimentin or fibronectin staining and/or an increase in E-cadherin staining as compared with the cells prior to being contacted with the LOX or LOXL inhibitor.

45. The method of clause 41, wherein the step of detecting includes detecting the invasiveness or migratory capacity of the cells in a scratch assay in vitro.

46. The method of clause 41, wherein the LOX or LOXL inhibitor is an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.

47. The method of clause 41, wherein the LOX or LOXL inhibitor is an antibody against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.

48. The method of clause 41, further comprising: contacting the cells with a therapeutic agent that is not the LOX or LOXL inhibitor in the presence of the LOX or LOXL inhibitor; and detecting a change in the viability of the cells.

49. A method for diagnosing cancer metastasis in a subject, comprising: assessing active LOX or LOXL levels or activity in the blood, wherein a change in active LOX or LOXL levels or activity in the blood in comparison with a reference sample indicates the presence of metastatic tumor growth.

50. The method of clause 49, wherein active LOX or LOXL levels or activities in the blood is lower than those in a reference sample indicates the presence or increase of cancer metastasis.

51. A method for diagnosing cancer metastasis in a subject having a tumor, comprising: assessing active LOX or LOXL levels or activity in the tumor, wherein a change in active LOX or LOXL levels or activity in the tumor in comparison with a reference sample indicates the presence of metastatic tumor growth.

52. The method of clause 49 or 51, wherein active LOX or LOXL levels or activities in the tumor is higher than those in a reference sample indicates the presence or increase of cancer metastasis.
53. The method of clause 49 or 51, wherein the step of assessing includes assessing the levels of the active LOX or LOXL using an antibody that binds to the active LOX or LOXL.

54. The method of clause 49 or 51, wherein the step of assessing includes assessing the levels of the active LOX or LOXL using an antibody that binds to the active LOX, LOXL2 or LOXL4.

55. The method of clause 49 or 51, wherein assessing comprises assessing the levels of the active LOX or LOXL using an antibody that binds to both active LOX and active LOXL2.

56. The method of clause 49 or 51, wherein the active LOX or LOXL is a mature form of LOX or LOXL after proteolytic processing of the preproprotein.

57. A method for monitoring a subject’s response to a therapy including a modulator of LOX/LOXL in the treatment of a disease, comprising: detecting a change in the level of C-reactive protein in the subject after administration of a modulator of LOX or LOXL to the subject, wherein the change indicates that the LOX or LOXL modulator has a therapeutic effect on the subject.

58. The method of clause 57, wherein the modulator of LOX or LOXL is an inhibitor of LOX or LOXL.

59. The method of clause 58, wherein a reduced level of C-reactive protein in a blood sample of the subject as compared to that prior to the administration of the LOX or LOXL inhibitor is indicative of the subject’s response to the treatment with the LOX or LOXL inhibitor.

60. The method of clause 58, wherein the disease is a disease associated with abnormal cell proliferation.

61. The method of clause 60, wherein the disease associated with abnormal cell proliferation is cancer, tumors, or restenosis.

62. The method of clause 58, wherein the disease is a fibrotic disease.

63. The method of clause 62, wherein the fibrotic disease is selected from dermal scar formation, keloids, liver fibrosis, lung fibrosis, kidney fibrosis, diabetic nephropathy, scleroderma, and glomerulosclerosis.

64. A method for treating a pathological cardiovascular condition or disease in a subject, comprising: administering to the subject an effective amount of an inhibitor of lysyl oxidase (LOX) or lysyl oxidase-like protein (LOXL).

65. The method of clause 64, wherein the inhibitor of LOX or LOXL inhibits an active form of LOX or LOXL.

66. The method of clause 64, wherein the pathological cardiovascular condition or disease is hypertension, hypertensive heart disease, myocardial infarction, atherosclerosis, or restenosis.

67. The method of clause 66, wherein the pathological cardiovascular condition or disease is associated with cardiovascular fibrosis and the inhibitor of LOX or LOXL is administered locally to the site of cardiovascular fibrosis.

68. The method of clause 67, wherein the inhibitor of LOX or LOXL is administered via a stent.

69. The method of clause 68, wherein the inhibitor of LOX or LOXL is coated on the stent.

70. The method of clause 67, wherein the inhibitor of LOX or LOXL is administered locally to the site of cardiovascular fibrosis via a catheter.

71. The method of clause 64, wherein the inhibitor of LOX or LOXL is administered prior to the onset of the pathological cardiovascular condition.

72. The method of clause 64, wherein the inhibitor of LOX or LOXL is administered after the onset of the pathological cardiovascular condition.

73. The method of clause 72, wherein the pathological cardiovascular condition is myocardial infarction, and the inhibitor of LOX or LOXL is administered at least 1, 2, 3, 5, or 10 hours after the myocardial infarction or 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, or 14 days after the myocardial infarction.

74. The method of clause 64, wherein the inhibitor of LOX or LOXL is an antibody or an antigen-binding fragment thereof against LOX or LOXL, a small molecule inhibitor, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.

75. The method of clause 64, wherein the inhibitor of LOX or LOXL is an antibody or an antigen-binding fragment thereof that specifically binds to a region of LOX or LOXL having an amino acid sequence selected from SEQ ID NOs: 1-18.

76. The method of clause 64, wherein the inhibitor of LOX or LOXL is an inhibitor of at least one of active LOX, LOXL2 or LOXL4.

77. The method of clause 64, wherein the inhibitor of LOX or LOXL inhibits both active LOX and active LOXL2.

78. The method of clause 64, wherein the active LOX or LOXL is a mature form of LOX or LOXL after proteolytic processing of a preproprotein form of LOX or LOXL.

79. A method for preventing a pathological cardiovascular condition or disease in a subject, comprising administering to the subject an effective amount of an inhibitor of lysyl oxidase (LOX) or lysyl oxidase-like protein (LOXL) prior to, concurrently, or after an adverse cardiovascular event.

80. The method of clause 79, wherein the adverse cardiovascular event is myocardial infarction.

81. The method of clause 79, wherein the adverse cardiovascular event is acute myocardial infarction.

82. The method of clause 79, wherein the inhibitor of LOX or LOXL is administered at least 1, 2, 3, 5, or 10 hours after the myocardial infarction, or 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, or 14 days after the myocardial infarction.
83. A device for preventing or treating a pathological cardiovascular condition or disease in a subject, comprising a component comprising an inhibitor of lysyl oxidase (LOX) or lysyl oxidase-like protein (LOXL).
84. The device of clause 83, wherein the component is a stent.
85. The device of clause 83, wherein the inhibitor of LOX or LOXL has a molecular weight below 500 Daltons.
86. The device of clause 85, wherein the inhibitor of LOX or LOXL is $\beta$-aminoproprionitrile (BAPN) coated on the stent.
87. The device of clause 83, further comprising a catheter for delivering the inhibitor of LOX or LOXL locally to the site of cardiovascular fibrosis caused by an adverse cardiovascular event.
88. A kit comprising a pharmaceutical composition comprising an inhibitor of LOX or LOXL and a pharmaceutically acceptable excipient; and instructions for how to treat or prevent a pathological cardiovascular condition or disease using the pharmaceutical composition.
89. A method for treating a disease associated with fibrosis in a subject, comprising administering to the subject an effective amount of an inhibitor of lysyl oxidase (LOX) or a lysyl oxidase-like protein (LOXL), wherein the fibrosis is selected from liver fibrosis, kidney fibrosis, lung fibrosis, dermal scarring, keloid formation, and Alzheimer's disease.
90. The method of clause 89, wherein the inhibitor of LOX or LOXL inhibits an active form of LOX or LOXL.
91. The method of clause 89, wherein the inhibitor of LOX or LOXL is an antibody or antigen-binding fragment thereof against LOX or LOXL, a small molecule inhibitor of LOX or LOXL, siRNA, shRNA or an antisense polynucleotide against LOX or LOXL.
92. The method of clause 89, wherein the LOX or LOXL inhibitor is an antibody or antigen-binding fragment thereof that specifically binds to a region of LOX or LOXL having an amino acid sequence selected from SEQ ID NOs: 1-18.
93. The method of clause 89, wherein the inhibitor of LOX or LOXL inhibits both active LOX and active LOXL2.
94. The method of clause 89, wherein the LOX or LOXL is a mature form of LOX or LOXL after proteolytic processing of a preproprotein.

Claims

1. A lysyl oxidase like protein 2 (LOXL2) inhibitor for use in a method of treating cancer or a cardiovascular disease or condition, wherein the inhibitor is an antibody or antigen-binding fragment thereof that specifically binds to LOXL2, a siRNA, a shRNA, or an antisense polynucleotide.

2. The LOXL2 inhibitor for use in a method according to claim 1, wherein the method prevents, inhibits, or reduces angiogenesis, tumor invasion, metastasis, or tumor growth, or increases survival of a subject with the cancer.

3. The LOXL2 inhibitor for use in a method according to claim 1 or claim 2, wherein the cancer is selected from the group consisting of lung cancer, breast cancer, colorectal cancer, pancreatic cancer, prostate cancer, skin cancer, bone cancer, ovarian cancer, liver cancer, anal cancer, bile duct cancer, esophageal cancer, leukemia, lymphoma, bladder cancer, uterine cancer, brain cancer, kidney cancer, cancer of the head and neck, cancer of the stomach, myeloma, testicular cancer, germ cell tumor, neuroendocrine tumor, cervical cancer, and gastrointestinal cancer.

4. The LOXL2 inhibitor for use in a method according to any of claims 1-3, wherein the inhibitor is an anti-LOXL2 antibody or antigen-binding fragment thereof.

5. The LOXL2 inhibitor for use in a method according to claim 4, wherein the antibody or fragment thereof is humanized or human.

6. The LOXL2 inhibitor for use in a method according to claim 4 or 5, wherein the antibody or antigen-binding fragment specifically binds within a region of LOXL2 having the enzyme domain, the copper binding domain and the catalytic domain.

7. The LOXL2 inhibitor for use in a method according to any of claims 4-6, wherein the antibody or antigen-binding fragment specifically binds to a region having an amino acid sequence selected from the group consisting of SEQ ID NOs: 3, 5, 7, 11, and 16.

8. The LOXL2 inhibitor for use in a method according to any of claims 1-7, wherein the inhibitor is administered in combination with an anti-neoplastic agent, a chemotherapeutic agent, an anti-angiogenic agent, or an anti-fibrotic agent.

9. An antibody or antigen-binding fragment thereof for use in a method of treating cancer or a cardiovascular disease or condition, wherein the antibody or antigen-binding fragment thereof specifically binds to an amino acid sequence selected from the group consisting of SEQ ID NOs: 1-18.

10. The antibody or antigen-binding fragment thereof of claim 9, wherein the antibody or antigen-binding fragment thereof specifically binds to lysyl oxidase (LOX).

11. The antibody or antigen-binding fragment thereof for use in a method according to claim 9, wherein the antibody or antigen-binding fragment thereof specifically binds to LOXL2.

12. The antibody or antigen-binding fragment thereof for use in a method according to any of claims 9-11, wherein the antibody or antigen-binding fragment thereof specifically binds to LOX and LOXL2.
13. The antibody or antigen-binding fragment thereof for use in a method according to any of claims 9-12, wherein the antibody or antigen-binding fragment is human or humanized.

14. A detection method, comprising detecting levels of LOX or one or more LOXL in a sample from a subject, wherein the levels indicate the presence of a tumor, metastasis, angiogenesis, fibrosis, or a cardiovascular condition in the subject.

15. The detection method of claim 14 comprises contacting the sample with an antibody or fragment thereof that specifically binds to LOX or one or more LOXL, and detecting binding of the antibody or fragment thereof to a protein in the sample.

\[ K_M = 0.5 \text{ ug/mL} \]

**Rate (RFU/sec)** vs. **[poly-D-Lysine] (ug/mL)**
Competitive inhibition
• Inhibitor typically bears structural similarity to substrate
• Inhibition noticeable at low substrate concentrations but can be overcome at high substrate concentrations

Uncompetitive inhibition
• Inhibitor binds at site that becomes available after substrate is bound at the active site
• Inhibition most noticeable at high substrate concentration

Non-competitive inhibition
• Inhibitor binds at site away from substrate binding site
• Relative inhibition is the same at all substrate concentrations

\[
\begin{align*}
E + S & \overset{K_S}{\rightleftharpoons} ES \xrightarrow{k_p} E + P \\
+ & + \\
I & I \\
\frac{K_i}{\alpha K_i} & \frac{\alpha K_S}{\alpha K_i} \\
EI + S & \overset{\alpha K_S}{\rightleftharpoons} ESI
\end{align*}
\]

If $\alpha < 1$ inhibitor is uncompetitive
If $\alpha = 1$ inhibitor is noncompetitive
If $\alpha \gg 1$ inhibitor is competitive
